Journal of the Royal Society of Arts.

No. 3,287. VOL. LXIV.

FRIDAY, NOVEMBER 19, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

ONE-HUNDRED-AND-SIXTY-SECOND SESSION, 1915-1916.

SESSIONAL ARRANGEMENTS.

The Opening Meeting of the One Hundred and Sixty-Second Session was held on Wednesday, November 17th, when an address was delivered by DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council. The subject of the address was, "English and German Methods Contrasted." (See pp. 6-16, below.) The chair was taken at 4.30 p.m.

PAPERS TO BE READ BEFORE CHRISTMAS.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

NOVEMBER 24.—SIR EDWIN PEARS, "Constantinople, Ancient and Modern." COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., will preside.

DECEMBER 1.—THE MASTER OF CHRIST'S COLLEGE, CAMBRIDGE (Arthur Everett Shipley, Sc.D., F.R.S.), "Insects and War." SIR WILLIAM J. COLLINS, K.C.V.O., M.S., F.R.C.S., will preside.

,, 8.—LIEUT.-COLONEL W. A. TILNEY, F.R.G.S., F.R.A.S., late 17th Lancers, "The Art of Finding your Way at Night without a Compass." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, will preside.

,, 15.—J. JEF. DENYN, Carillonneur de Malines, and WILLIAM W. STARMER, F.R.A.M., "Carillons and Carillon Playing." (With Illustrations.)

COLONIAL SECTION.

Tuesday afternoon at 4.30 p.m. :—

NOVEMBER 30.—SIR SYDNEY OLIVIER, K.C.M.G., late Governor of Jamaica, "Recent Developments in Jamaica: Internal and External." SIR HENRY A. BLAKE, G.C.M.G., will preside.

INDIAN SECTION.

Thursday afternoon, at 4.30 p.m. :—

DECEMBER 16.—C. C. McLEOD, President of the London Jute Association, "The Indian Jute Industry." SIR JOHN PRESCOTT HEWETT, G.C.S.I., C.I.E., will preside.

PAPERS TO BE READ AFTER CHRISTMAS.

PROFESSOR J. A. FLEMING, M.A., D.Sc., F.R.S., "The Organisation of Scientific Research." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, will preside.

R. W. SETON-WATSON, D.Litt., "The Balkan Problem."

CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Optical Appliances in Warfare."

LAWRENCE CHUBB, "The Common Lands of London: the Story of their Preservation."

REV. P. H. DITCHFIELD, "The England of Shakespeare."

W. A. CRAIGIE, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

VICTOR HORTA, Directeur de l'Académie Royale des Beaux-Arts de la Ville de Bruxelles, "Belgian Architecture."

CHARLES DELCHEVALERIE, "Belgian Literature."

LESLIE URQUHART, "The Economic Development of Russia."

J. ARTHUR HUTTON, Chairman of the British Cotton Growing Association, "The Effect of the War on Cotton Growing in the British Empire."

S. CHARLES PHILLIPS, M.S.C.I., "Paper Supplies as affected by the War."

PROFESSOR T. G. MASARYK, "The Slavonic Peoples."

COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., late Survey of India, "The Romance of the Indian Ordnance Survey."

SIR DANIEL MORRIS, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland."

PROFESSOR WYNDHAM R. DUNSTAN, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m. :—

January 13, February 17, March 16, April 6, May 18.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m. :—

February 1, March 7, May 2.

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m. :—

WALTER ROSENHAIN, D.Sc., F.R.S., Superintendent, Metallurgy Department, National Physical Laboratory, "Optical Glass." Three Lectures.

LECTURE I.—NOVEMBER 29.—Comparison of optical with ordinary glass—Defects and properties of glass for optical purposes—Transparency—Colour—Bubbles and defects—Striæ or veins—Internal strain and annealing—Hardness and durability—Testing of optical glass—The optical properties of glass—Refraction and dispersion—Their relation in crown and flint glasses—Glasses introduced by Schott and Abbe—Partial dispersions and the secondary spectrum—Apochromatic glasses and lenses.

LECTURE II.—DECEMBER 6.—History of optical glass manufacture—Fraunhofer, Guinand, Feil, Bontemps, Chance—Schott and Abbe—Hopkinson and Stokes—Efforts in England. The present method of optical glass manufacture—The furnace—The pot—Production and treatment—The process of melting and fining—Stirring and finishing—Cooling—Breaking up, selecting and moulding—Annealing—The final form of the glass.

LECTURE III.—DECEMBER 13.—The present process of manufacture—General difficulties—Costliness—Cost of the pot—Time of production—Cost of melting—Raw materials—Low yield of good glass—Risks of the process—Risks of loss during melting—Failures due to striæ—Risks of contamination—Errors and variations of optical constants—Range of glasses demanded by opticians—Small quantities required—Need for large stock of optical glass. Special difficulties in England—Cost of raw materials and of labour—Refractories. Special difficulties connected with "new" glasses—Their chemical activity—Action on pots—Absorption of colouring impurities—Attainment of extreme optical properties. Need for research—The general problem—How to make good optical glass—Necessary improvements in pots and refractories, and in furnaces and methods of working—Utilisation of new materials and electric methods—The special problems relating to individual types of glasses—Optical and other properties to be realised simultaneously—The limitations of possible glasses—Optical properties of crystalline media—Future possibilities.

FOTHERGILL LECTURES.

Monday afternoons, at 4.30 p.m.:—

REV. DR. HERBERT WEST, D.D., A.R.I.B.A. (author of "Gothic Architecture in England and France"), "Flemish Architecture." Three Lectures.

February 7, 14, 21.

EDWARD A. REEVES, F.R.A.S., Map Curator, Royal Geographical Society, "Surveying." Three Lectures.

March 27, April 3, 10.

J. ERSKINE-MURRAY, D.Sc., F.R.S.E., M.I.E.E., "Vibrations, Waves, and Resonance." Four Lectures.

May 1, 8, 15, 22.

JUVENILE LECTURES.

These Lectures will be given on Wednesday afternoons, January 5 and 12, at 3 p.m. The Lecturer and Subject will be announced later on in the *Journal*.

PROCEEDINGS OF THE SOCIETY.

THE SOCIETY was founded in 1754, and incorporated by Royal Charter in 1847, for "The Encouragement of the Arts, Manufactures, and Commerce of the Country, by bestowing rewards for such productions, inventions, or improvements as tend to the employment of the poor, to the increase of trade, and to the riches and honour of the kingdom: and for meritorious works in the various departments of the Fine Arts; for Discoveries, Inventions, and Improvements in Agriculture, Chemistry, Mechanics, Manufactures, and other useful Arts; for the application of such natural and artificial products, whether of Home, Colonial, or Foreign growth and manufacture, as may appear likely to afford fresh objects of industry, and to increase the trade of the realm by extending the sphere of British commerce; and generally to assist in the advancement, development, and practical application of every department of science in connection with the Arts, Manufactures, and Commerce of this country." In 1908 the Society was granted the privilege of adding "Royal" to its title.

FELLOWSHIP.—At the Annual General Meeting held on June 24th, 1914, a By-Law was made authorising all Members of the Society to use the designation of Fellow.

ORDINARY MEETINGS.—Meetings are held every Wednesday during the Session (November to June), at which papers on subjects relating to inventions, improvements, discoveries, and other matters connected with Arts, Manufactures and Commerce are read and discussed.

INDIAN SECTION.—This Section was established in 1869, for the discussion of subjects connected with the Indian Empire. Six or more Meetings are held during the Session.

Colonial Section.—This Section was formed in 1874 under the title of the African Section. It was enlarged in 1879, to include the consideration of subjects connected with the Colonies and Dependencies. Four or more Meetings are held during the Session.

Cantor Lectures.—These Lectures originated in 1863, with a bequest by Dr. Cantor. The Lectures deal with the latest applications of Science and Art to practical purposes, and are, as far as possible, experimentally illustrated.

Fothergill Lectures.—Courses of Lectures, similar to the Cantor Lectures, are given from time to time under this bequest.

Howard Lectures.—The bequest of Mr. Thomas Howard (1872) is now devoted to occasional courses of Lectures on motive power and its applications.

Shaw Lectures.—Under the Shaw bequest Lectures on Industrial Hygiene are given from time to time.

Aldred Lecture.—The bequest of the late Dr. Aldred has been devoted to the establishment of an Annual Lecture.

Cobb Lectures.—Funds have been provided for occasional Lectures in memory of the late Mr. Francis Cobb.

Juvenile Lectures.—A Short Course of Lectures, suited for a Juvenile audience, is delivered to the children of Fellows during the Christmas holidays.

Admission to Meetings. — Fellows have the right of attending the above Meetings and Lectures. They require no tickets, but are admitted on signing their names. Every Fellow can admit two friends to the Ordinary and Sectional Meetings, and to the Cantor and other Lectures. Books of tickets for the purpose are supplied, but admission can also be obtained on the personal introduction of a Fellow. For the Juvenile Lectures special tickets are issued.

Journal of the Royal Society of Arts.—The *Journal*, which is sent free to Fellows, is published weekly, and contains full Reports of all the Society's Proceedings, as well as a variety of information connected with Arts, Manufactures and Commerce.

Examinations.—Examinations, founded in 1854, are held annually by the Society, through the agency of Local Committees, at various centres in the country. They are open to any person. The subjects include the principal elements of Commercial Education and Music. Full particulars of the Examinations can be had on application to the Secretary.

Library and Reading-room.—The Library and Reading-room are open to Fellows, who are also entitled to borrow books.

A History of the Society has lately been published (John Murray, pp. 558, 15*s.* net) and can be obtained from any bookseller. It gives a history of the Society's work from 1754 to 1880.

Conversazioni are held, to which Fellows are invited, each Fellow receiving a card for himself and a lady.

Election of Fellows.—Candidates are proposed by Three Fellows, one of whom, at least, must sign on personal knowledge; or are nominated by the Council.

The Annual Subscription is Two Guineas, payable in advance, and dates from the quarter-day preceding election; or a Life Subscription of Twenty Guineas may be paid. There is no Entrance Fee.

CALENDAR FOR THE SESSION.

The following is the Calendar for the Session 1915–1916. It is issued subject to any necessary alterations :—

The Cantor Lectures, the Fothergill Lectures, the Ordinary Meetings, and the Meetings of the Indian and Colonial Sections (unless otherwise announced) will commence at Half-past Four o'clock.

The Annual General Meeting will be held at Four o'clock.

The Juvenile Lectures will be given at Three o'clock.

PROCEEDINGS OF THE SOCIETY.

FIRST ORDINARY MEETING.

Wednesday, November 17th, 1915; DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Alexander, Alexander, National Gum and Mica Company, 59th Street and 11th Avenue, New York City, U.S.A.

Ardaseer, J. Grenville, Worli Hill, Bombay, India, and Olney House, Richmond, Surrey.

Audy, Alphonse William, 33, Civil Lines, Poona, India.

Baldwin, Mrs. Edith Brake, 24, Avenue-road, Leamington Spa.

Basu, Narendra Kumar, 99, Upper Circular-road, Calcutta, India.

Bhattacharyya, Jyotischandra, M.A., B.L., Purnea, Bihar, India.

Bhore, Joseph W., B.A., I.C.S. (Diwan of Cochin), Ernakulam, Cochin, South India.

Bloxam, John Astley, F.R.C.S., J.P., The Old Malt House, near Maidenhead, Berks.

Buckley, Edward S., jun., 2039 Sansom-street, Philadelphia, Pa., U.S.A.

Cardona, Joseph M., 1917, Catamarca-street, Rosario, Argentine Republic.

Chance, Clinton Frederick, B.A., 12, Arthur-road, Edgbaston.

Chu Ju, General Chiang Chun Yamen, Chekiang, China.

Clark, The Hon. Sir William Henry, K.C.S.I., C.M.G., Windcliffe, Simla, India.

Davson, Edward R., 20, Ennismore-gardens, S.W.

Dholpur, His Highness the Maharaj Rana of, Dholpur State, India.

Evans, Gerald A., LL.B., J.P., P.O. Box 151, Pietersburg, N. Transvaal, South Africa.

Furness, Horace Howard, jun., 2034, De Lancey-place, Philadelphia, Pa., U.S.A.

Gibbs, A. E., Pennsylvania Salt Manufacturing Company, Greenwich Point, Philadelphia, U.S.A.

Gwalior, Major-General His Highness The Maharaja of (Sir Madho Rao Sindhia Bahadur), G.C.S.I., G.C.V.O., LL.D., A.D.C., Madho Bilas, Sipri, Gwalior, India.

Ingels, Lionel, 5, Grosvenor House, Calcutta, India.

Lambagraon, Lieut.-Colonel the Hon. Raja Jai Chand of, C.S.I., Lambagraon, Kangra District, Punjab, India.

Leech, Arthur John, The Palms, College-road, Madras, India.

Liebert, William Ernest Cato, Messrs. Huttenbach Bros. & Co., Penang, Straits Settlements.

Lord, James Spain, Dover House, Bridge-street, Canterbury.

McCorry, Joseph James, 73, University-avenue, Belfast.

Miln, David Anderson, LL.B., M.A. (Edin.), 30, Greencroft-gardens, South Hampstead, N.W.

Mitchell, Alfred H., M.I.Mech.E., Port of London Authority, Elevator Dock, Silvertown, E.

Musgrave, Henry Arthur Fitzherbert, United Service Club, Calcutta, India.

Naidu, P. N. Muthuswami, B.A., Pagadala Bagh, Saidapet, Madras, India.

O'Callaghan, Major-General Sir Desmond D. T., R.A., K.C.V.O., 53, Iverna-court, Kensington, W.

Pite, Professor Arthur Beresford, F.R.I.B.A., 21, Willow-road, Hampstead, N.W.

Renult, William, 141, Broadway, New York City, U.S.A.

Showers, St. George, 32, Elm Park-road, S.W.

Singh (of Kapurthala), Sirdar Charanjit, Chadwick, Simla, India.

Singh, Rai Bahadur Choudri Amar, P.O. Pali, Dist. Bulandshare, United Provinces, India.

Smith, Alexander, 21, Oakshaw-street, Paisley, Scotland.

Smith, Lieut.-Colonel Thomas, V.D., The Muir Mills Co., Ltd., Cawnpore, India.

Sundaracharlu, S. K., M.A., Tahsildar, Tindivanam, South India.

Thorne, Mathew Henry, Rua Padrão, Vallongo, Portugal.

Vanderlip, Frank Arthur, A.M., LL.D., National City Bank, New York City, U.S.A.

The CHAIRMAN delivered the following

ADDRESS.

The Royal Society of Arts, to which we have the honour to belong, now enters upon the 162nd year of its existence in the culminating stage of the greatest war the world has yet seen. Our Society has had a long, useful and distinguished career, and it is our duty, as its present members, to see to it that its power for good is maintained and its beneficent course continued to aid a future England, as it has undoubtedly assisted the England of the past. Our Society is a characteristically English institution, and its proceedings faithfully reflect the numerous incidents of the progress of our Empire through the dawn and rise of industrial civilisation. All the great matters of national, Imperial, and industrial development are to be found fully discussed in our Proceedings for more than a century and a half.

In ordinary times your Chairman addressed you on matters in the field in which he had won his reputation. I propose to deviate from this course, and so avoid inflicting upon you a technical engineering address on gaseous explosions and the internal-combustion engine.

It seems to me more appropriate in these stirring and critical times to reflect the current of all our thoughts, and to express my appreciation of the high honour of acting as your Chairman by attempting a defence of England's position under the title of "English and German Methods Contrasted."

Friends and foes agree as to England's success, but find great difficulty in understanding the reason why.

Our friends see in our proceedings a lack of order and method, and attribute our position in the world to a large extent to our good fortune in being early in the field; we became, they think, the first of the world's industrial nations by a happy combination of circumstances independently of any particular qualities of our own. This is evident from the expressions used by friendly nationalities towards England and Englishmen.

One able writer of foreign extraction, in a recent article, refers to England as "unpractical, illogical, idealistic, laughing England." Another speaks of England's extraordinary facility for "muddling through." Our enemies, the Germans, while agreeing that England has built up a mighty empire, "which is the object of all policy," assert that this has been accomplished with a complete disregard of political morality.

Bernhardi says: "We must not deceive ourselves as to the principles of this English policy. We must realise to ourselves that it is guided exclusively by unscrupulous selfishness, that it shrinks from no means of accomplishing its aims, and thus shows admirable diplomatic skill." Bernhardi's idea is in opposition to the friendly view, and is shared by numerous enemy writers.

Our own Professor Seeley, in his great work on "The Expansion of England," makes the much quoted statement: "We seem, as it were, to have conquered and peopled half the world in a fit of absence of mind."

We ourselves know that we have built up a world civilisation, but doubt grievously as to its lasting power. Some business men even consider our commercial ruin as imminent. Mr. Chamberlain predicted this as our fate in 1903. Even in 1915, we are assured by many of our professor friends that unless we organise we shall become bankrupt in a few years, victims to the superior systems of Germany and America. German methods especially are extolled as worthy of our imitation, and they are continually contrasted with English, greatly to our disadvantage. The German methods are stated to be scientific, accurate and far-sighted; the English, amateurish, inaccurate and short-sighted.

Professor Unwin and Dr. Hele-Shaw, in recent addresses, expressed themselves as much impressed by the fact that Germany's output of pig iron and steel is now nearly double that of England. Professor Unwin says: "Although Germany has on the whole poorer qualities of iron ore and coal, her production of pig iron has increased from 11,000,000 to 19,000,000 tons annually, while ours increased only from 9,000,000 to 11,000,000 tons. To-day her production of steel is nearly twice as great as ours." Dr. Hele-Shaw also calls attention to Germany's increased steel production, and he evidently fears the competition of Germany after the war. He states: "As I have already quoted, Germany's power in war is admitted to be her mechanical organisation, and the organisation of every material and engineering force to that end. Just as striking, if not more so, is her organisation for the arts of peace, and I lately heard a very shrewd man of affairs express his amazement at Germany's entrance into war, when by peacefully pursuing the way she was going she would have dominated the world commercially in a few years' time, and, in the words of the speaker, might in many manufactures have made us practically bankrupt. It is undoubtedly in the matter of scientific organisation even more than the organisation of science that Germany has achieved such wonderful results, and it is therefore in this direction that we must leave no stone unturned if we wish to have any chance of holding our own in the future." Those two distinguished engineers obviously think our country in a bad way.

The chemists, too, are of the same opinion. In this very hall Lord Moulton has said: "After the war, if we do not effect a change, the textile industries would step into a slavery to the Germans as great as that in which they hope to put us in a political and military sense." Dr. Foster, the treasurer of the Chemical Society, has also said: "The Germans are so imbued with the need of pursuing modern and efficient methods of education, in applying science to industry, that they hold in contempt a country which notoriously neglects such processes."

English methods are called in question also by literary men, politicians, and even an Admiral.

In the late Professor Cramb's most interesting work, "Germany and England," is found the following. Speaking of Germany, he says: "From Austria and from France she had endured insult upon insult, measureless humiliations. But from England?

"England's possessions, England's arrogance on the seas, her claim to world-wide empire—these, Germany answers, are to Germany an insult not less humiliating than any she has met with in her past. And what are these English pretensions? And upon what are they based? Not upon England's supremacy in character or intellect. For what is the character of this race which thus possesses a fifth of the habitable globe and stands for ever in the path of Germany's course towards her 'place in the sun,' in the path of Germany's course towards empire? . . . England's supremacy is an unreality, her political power is as hollow as her moral virtues, the one an arrogance and pretence, the other hypocrisy. She cannot long maintain that baseless supremacy. On the sea she is being rapidly approached by other Powers; her resources, except by immigration, are almost stationary, and her very immigration debases still further her resources. Her decline is certain. There may be no war. The display of power may be enough, and England, after 1900, like Venice after 1500, will gradually atrophy, sunk in torpor." This, Professor Cramb states, is the German indictment of England.

His own view is thus given: "When, turning to England, I consider the apathy or the stolid indifference of the nation—when, for instance, I consider the deliberate and hostile silence or loud calumnies which, for the past seven years, have accompanied Lord Roberts's crusade; and when, over against this apathy, I survey in this month of February, 1913, the energy, the single devoted purposefulness throbbing everywhere throughout Germany, her forward-ranging effort, her inner life, her army, her fleet, I seem to hear again the thunder of the footsteps of a great host. . . . It is the war bands of Alaric!"

Professor Cramb obviously did not approve of the methods of his countrymen.

Politicians also bring this charge of apathy, and frequently exhort England and its men of business to "wake up."

One would have thought that at least our Navy was sound, but we are informed by Lord Charles Beresford, in a remarkable book entitled "The Betrayal," published in 1912, that even there no safety is to be found. This book is an indictment of the entire Navy, as to its organisation, ships, and officers. The very titles of the chapters are alarming. Take, for example, "Ships without Docks," "The Delusion of the 'Dreadnought' Policy," "The Fraud on the Public," "How Not to Do it," and so on.

Lord Charles Beresford alludes to the great North Sea concentration as the "scrapping policy." He objects to the whole principle of the "Dreadnoughts," and considers their building only led the British public into a delusion, from which they were still suffering in 1912, and one objection he makes is sufficiently surprising: "In 1906 the tradition of dignity and courtesy hitherto prevailing in the Service was rudely violated, and Great Britain proclaimed herself the Bully of the Seas."

He objects to the "Dreadnoughts" for a singular reason: "The British traditional policy was reversed in another respect. Hitherto it had been our practice to keep so powerful a margin of strength in ships that we could afford to await the result of the experiments of other Powers. In due time, when it became clear what our requirements with regard to other Powers were, we proceeded to fulfil them."

According to Lord Charles Beresford, in building the "Dreadnought" the Admiralty boasted that we led the world, and this statement, he says, was false.

In another part of the book, speaking of the Home Fleet, he states: "I said privately at the time, and I say publicly now, that the Home Fleet was a fraud on the public and a danger to the State."

Engineers, chemists, literary men, politicians, and an Admiral, have all protested in effect the inferiority of our methods and the superiority of the German. According to this school of thought we can only be saved from national, industrial, and scientific extinction by humbly following the German lead, and copying her institutions as closely as our limited intelligence permits.

Now, is all this true? Is German success so great and ours so small? How do we compare with Germany in peace and in war?

It is quite true that Germans now manufacture more steel per annum than we do. It is true that they supplied us with dyes for use in our textile industries. It is true that they organised industry for the purpose of raising prices, and carried out the Kartell system, so as to produce powerful combinations of separate business organisations, such as the Rhenish Westphalian Coal Kartell, the Westphalian Coke Kartell, the Wire Kartell, and syndicates also of the pig-iron, the half-finished iron and steel.

It is true that for many years they have directed their organisations to the purpose of war, and inspired their whole people with a hatred of England, because of the insult of our world-wide Empire, and the annoying universality of the English flag upon the seas of the world.

It is true that Lord Fisher effected the great North Sea concentration of our Fleet; it is true that England designed the "Dreadnought" type of battleship, and invented numberless mechanisms to make it a success; and it is true that some of our politicians, in the heat of argument, carried their dissensions to such intensity as to encourage the Kaiser in vain hopes; but it is not true that these facts, looked at in their proper light, in any way shew England's methods to be unsuccessful or England's position to be unsafe in the world.

In times of peace nations must depend one upon the other for products which each is particularly suited to produce. It is misleading, for example, to cite the relative production of pig-iron and steel as proving either the prosperity of Germany or the decadence of England. A very slight examination shows this to be so. The United Kingdom, for example, has a total of 23,417 miles of railway, and an area, roughly, of 121,000 square miles. Germany has now 37,949 miles of railway, and an area of 242,867 square miles. Germany has abundant store of ores, fit for reduction by the basic steel process—the invention of English metallurgists, Thomas and Gilchrist—and it would indeed be extraordinary if a capable and industrious nation such as the Germans are, with all their faults, could not succeed in making most of the steel required for their own uses. It is obvious, from the most cursory glance at German exports and imports, that the greater quantity of steel made by her is used at home. We do not hear anything of the relative decadence of Germany as compared with America, and yet the American production of steel exceeds the German in nearly the same ratio as Germany exceeds England. The reason for the greater production in America is the same, that American railways again exceed in mileage the German. The area of the United States is, roughly, 3,571,223 square miles, and the railways are 246,573 miles. Notwithstanding this enormous production of steel in both Germany and America, steel exports do not form a large proportion of the total of either country.

Again, while our chemists can point to the German predominance in dyes, England can point to whole districts of Germany which depend for the prosperity of their textile mills upon yarn spun in Lancashire and upon machinery made there. At the present moment these industries are brought to an absolute standstill by the lack of English yarn. Germans might well use Lord Moulton's words, and say that the German industries are under the same tyranny which England holds over the world, by what they are pleased to call the lack of freedom of the seas. Quite a number of German industries absolutely depend on England for their success.

If comparative magnitude of industries is to be taken as the standard of success, then England can point to her shipbuilding, marine engineering, her ocean carrying trade, her cotton and woollen textile industries, her huge coal-mining industry, and others in which she is supreme in the world.

Take shipbuilding for example. In the year 1911, the United Kingdom built 69 per cent., and Germany only 9·7 per cent., of all the vessels launched in the world during that year. Germany's shipbuilding thus only amounted to about one-seventh that of Britain. In the same year the United Kingdom owned 46 per cent. of the total sea tonnage of the world, and Germany 11 per cent., less than one-fourth of Britain. Shipbuilding naturally varies considerably with the demand, but Britain builds on an average about 60 per cent. of the world's output in each year. Many of these ships are built for other nations, including Germany, but nevertheless British-owned shipping remains supreme in tonnage, quality, and capability of the vessels comprising our mercantile fleet. Naturally, as our shipbuilding and shipping output leads all others, our marine engineering industry is also much the greatest in the world.

In the textile industries, too, we are supreme. This can be most easily seen by comparing the numbers of the world's cotton spindles at a recent date. In 1912, our mills in the United Kingdom contained 55,165,000 spindles. Germany, Austria-Hungary, Italy, Russia and France, only contained among them 36,139,000 spindles. Practically the whole continent of Europe thus only contained less than three-fourths of our spindles. The United States mills contained 29,523,000 spindles.

Now with regard to coal production. In 1911, the coal-mining industry of the United Kingdom raised 271·9 million tons; Germany, 158·2 million tons; and the United States, 443 million tons. The United States is thus the greatest coal-producing country in the world; Britain comes second, and Germany third.

Compared to Germany by the magnitude standard, Britain, from these figures, must be considered superior. The intensity of industrial effort, however, in different countries is measured best by the actual consumption of coal per head of the population of each country. In the same year, the United States consumed 4·54 tons per head, the United Kingdom 4·08 tons, and Germany 2·03 tons. These figures show clearly that America and England have reached a higher stage of industrial civilisation than Germany. The larger coal consumption shows that America and England require greater motive power and greater use of fuel for metallurgical and other processes than Germany.

These examples deal only with a few industries, and it may be argued by the upholders of Germany that, notwithstanding our supremacy in some, yet on the whole British industry is out-distanced by the German. Such a statement can be tested by comparing the total external trade of the countries one with another, that is, the imports plus the exports. In 1911, the total external trade of the United Kingdom was £1,031,000,000; the German, £807,000,000; and the United States of America, £671,000,000. In 1912, the British total external trade rose to £1,344,000,000. The German and American figures are not yet available, but it is certain that in total trade England remains well in advance of Germany.

Another test of the success of a nation is to be found in the difference between imports and exports. In a highly successful nation, the imports are always greater in money value than the exports, and the difference between imports and exports indicates the earnings of the country from foreign nations by means of shipping, banking, engineering design, and investments in foreign undertakings.

In time of peace, the excess of imports represents the payment to the British for services rendered outside of the export of goods in that particular year, and the sum naturally varies from year to year, and is greater over a series of years in Britain than in any other country. England is the great creditor nation of the world.

Tried in all these ways, industrial England must be considered as highly successful; but no country can be deemed really successful nationally unless it contrives to supply its people with sufficient food, for physical efficiency, comfortable clothing, and suitable housing. Physical comfort can best be judged by considering the income of the nation per head of the population, and in considering this adopting a standard of rea income—that is, income in terms of the things required for subsistence and comfort which we can afford to get. Tested in this way, Germany compared to England is a poor country. Her average income per head of the population is but little more than half ours. Before the war, the total income of the United Kingdom was about £2,400,000,000, or £53 per head per annum of our population. The German figure is something like £30 per head. Even Bernhardi admits the superior prosperity of England from this point of view, although he deals with a more elusive figure than income, viz., that of capital. He states that throughout the German Empire the capital in 1911 was between 5,000 and 6,000 Marks per head of the population. He credits England with 6,000 to 7,000 Marks per head. Capital value, however, is not in my view so reliable for our purpose as total income. The income gives the actual working wealth capable of application in various ways. The capital is so much of it fixed that there is no possibility of changing or liquidating so as to apply to any other than one purpose. Without doubt, the average Englishman, from the physical comfort standpoint, is much better situated than the average German. His wages are higher, his food is cheaper, his housing is better, and his hours of labour are shorter than the German's. He has a better chance of improving himself physically and intellectually.

Whatever then be the German organisation for the arts of peace, and whatever be our lack of method or organisation, all tests which can be applied show the English as a nation to have attained greatly superior results as compared with Germany.

We are particularly characterised as unscientific in our methods. It is difficult to see exactly what is meant by this statement, but many of our professors continually proclaim, like Dr. Foster, our national neglect of science, especially in its application to industry.

An examination of the leading scientific work of England shows that it is always brilliant, far-reaching, and early in the field. Practically all fundamental discoveries in science have originated in England, France, or Italy. Germany's scientific work is undoubtedly of an important kind, but it is always of what may be called the "pedestrian" type; hard-working and plodding, but with little foresight or brilliancy.

The scientific discoveries of England in the

nineteenth century are numerous. For example, in the domain of heat, the whole science of thermodynamics was originated and worked out between France and England. One of the two great fundamental discoveries in thermodynamics, the Carnot cycle, was made in France early in the nineteenth century; the fundamental work of Joule, of Manchester, determined the other, the mechanical equivalent of heat, about 1840; and the subsequent work of MacQuorn Rankine and Lord Kelvin in England co-ordinated Carnot's and Joule's discoveries, and produced the two great thermodynamic laws—the first, the mechanical equivalent of heat, and the second, the limitation of heat conversion into work depending upon the temperature of source and the temperature of discharge.

The German physicists Meyer and Clausius also did good work, but its importance was secondary compared to that of the English investigators.

In electricity also the greatest discoveries fall to England. Faraday's discovery of the production of electric currents by motion of a conductor in a magnetic field was one of the most fundamental and far-reaching ever made. All subsequent work resulting in the production of the dynamo and electric motor, and the huge power and lighting electrical developments of to-day, flowed from Faraday's discovery made at the Royal Institution in Albemarle Street, London.

In the theory of light also, work of fundamental importance was due to English physicists from Thomas Young to Clerk-Maxwell and Poynting. Clerk-Maxwell's electromagnetic theory of light was used in predicting the existence of ether waves travelling through space at the same velocity as light, but with wave-lengths incomparably greater. Clerk-Maxwell's work, in fact, suggested wireless telegraphy. It is true that Hertz, a German, and an able experimenter, was the first to design apparatus whereby what is called the "wireless wave" could be sent through a short space and detected, but Hertz's work could not have existed without the prior work of Clerk-Maxwell.

The work of Sir William Crookes also, and his study of the various phenomena of electrical discharge in high vacua, disclosed effects hitherto unsuspected, and enabled him to produce rays within an evacuated bulb which could be caused to act upon the molecules so as to make them bombard pieces of metal and refractory material placed within the bulbs, the material being actually rendered incandescent by the bombardment of the invisible molecules. Crookes' work suggested developments which were taken up in Germany, and one result was the discovery of Röntgen's rays. Röntgen, a German, is a man of scientific merit without doubt, but he followed Crookes—he did not lead him. Another wonderful discovery of Sir William Crookes led to the radiometer, and this led to other discoveries made by both English and Continental scientific men.

England, too, was first in the investigation of liquefied air, hydrogen, and other gases. It is true that the French physicist, Cailletet, had previously liquefied air on a very small scale within a tube, but it remained without effect upon our knowledge of low temperatures until Sir James Dewar, by designing and installing large apparatus, succeeded in producing liquid air at a temperature below its boiling-point, so that it could be poured from vessel to vessel in the open atmosphere. A whole series of interesting discoveries were made by Sir James Dewar and his English and Continental followers in connection with low temperatures.

The work of Clerk-Maxwell, Crookes, and Dewar led to discoveries as to the nature of the atom, and this subject was taken up in the most brilliant manner by Sir J. J. Thomson. From his work a whole new science has sprung, and the twentieth century may be hereafter known as the century of the atom and the molecule.

The names of Sir William Huggins and Sir Norman Lockyer show that England has not neglected solar and stellar spectroscopic research.

Atomic and molecular knowledge has increased notably since the discovery of radium. Originally radio-activity was discovered by a French physicist, Becquerel. Professor and Madame Curie, working on the known fact of the radioactivity of certain ores, succeeded in concentrating the part to which this peculiar property was due, and produced radium bromide. To the French is due this brilliant discovery; but to the English investigators, Professor Rutherford of Manchester, Professor Bragg of Leeds, Professor Strutt of London, and Professor Soddy of Glasgow, is due the wonderful modern development which gives a complete history of atomic disintegration and enables us to realise the enormous energy stored up in the atom. Bragg's work, too, upon the structure of the crystal, as determined by the X-rays, brilliantly follows up the other recent knowledge.

In scientific chemical discovery we have not been behind, as is proved by the mere mention

of the great English names: John Dalton, Humphry Davy, Michael Faraday, Thomas Graham, Thomas Andrews, William Robert Grove, Edward Frankland, William Crookes, and William Henry Perkin, which at once call to mind the great fundamental matters; the atomic theory; the electrolytic decomposition of the alkalies; nitro-benzole; gaseous diffusion; critical temperatures of gases; the gas battery; thallium; and aniline dyes. The work of Lord Rayleigh and Sir William Ramsay resulted in the discovery of argon, a gas which had been hinted of as existing in the atmosphere more than a hundred years ago by Cavendish. The discovery, too, of helium as a decomposition product from radium emanations by Ramsay is one of the first importance.

In biology also English scientific men take a leading place. Darwin was a man of a century, and the mass of biological investigation at present in progress in England is surpassed in its results by no German work.

In pure science, whatever opinion may be held as to our methods, our results greatly surpass those of Germany.

The invention of England, too, is more important than that of Germany. English inventors created the steam-engine, applied it first to pumping, then to factories, and later to marine propulsion and railway locomotives. All the great steam inventions of the past 150 years have been English, or rather, British—separate condenser, high-pressure, expansion, compounding, tripling, and, last of all, the greatest steam invention since the time of James Watt, the steam turbine, all purely British.

In electricity, too, England has taken a most important part in the development of Faraday's discovery; the magneto, the dynamo, and the investigation of the fundamental laws of dynamo and motor, are all English.

The incandescent electric lamp was the simultaneous production of the Englishman, Swan, and the American, Edison.

Telegraphy, too, has been largely developed in England. The inventions of Lord Kelvin, the mirror-galvanometer, the syphon recorder, and his studies of induction in submarine cables, made transatlantic telegraphy possible. The modern developments in transatlantic telegraphy are also English. The invention of Mr. Sydney Brown enabled the syphon recorder to be modified so as to print in type in the same manner as an ordinary receiving printing instrument.

In wireless telegraphy, too, the first application of the work of Clerk-Maxwell in England and of Hertz in Germany was made by Sir Oliver Lodge, and his discoveries form the basis of much of the successful wireless telegraphy of the world. The brilliant Italian, Marconi, of Italian and British parentage, by his genius perfected the wireless telegraphic methods in such a way as to combine physics with engineering, and sent messages across the sea in some cases to the enormous distance of 6,000 miles. Marconi carried out the most of his work in England with the assistance of English physicists and engineers.

In the application of the science of thermodynamics to both the steam and internal-combustion engines, England has taken a leading part. Our committees and investigators have been most energetic.

England was early in the field in internal-combustion engineering work. Professor Farish (1817), the Rev. William Cecil (1820), and Samuel Brown (1823), followed by a long line of inventors, have worked conscientiously and successfully in developing both steam and internal-combustion engines to make them fit for the great modern purposes of driving fixed machinery, motor-cars, and aircraft. In this work it is true America led with the flying machine, by Professor Langley's brilliant work resulting ultimately in the successful application of the internal-combustion engine to flight by the brothers Wright.

By the work of the Advisory Committee on Aeronautics, the National Physical Laboratory, and the Government Aircraft Factory, acting in combination with private firms and inventors, most successful aeroplanes have been produced, and the superiority of the British aeroplane has been distinctly proved in the present war.

England, too, has been most fortunate in her great societies and institutions for the advancement of scientific knowledge, industrial knowledge, and the application of such knowledge to the general purposes of civilisation. The oldest of these great and useful institutions is the Royal Society, instituted in 1662. Next is the Royal Society of Arts, dating from 1754, now beginning its one hundred and sixty-second session; followed by the Royal Institution, established in 1800. The great technical institutions also are the Institution of Civil Engineers, established January, 1818, and the Institution of Mechanical Engineers, established 1847. The discoveries made by the Fellows of the Royal Society and by the professors of the Royal Institution are unrivalled in the world. The

application of science to our industries has been and now is very substantially advanced by the activity of our own society. The Royal Society of Arts and our two great engineering institutions have accomplished great things. No German institutions approach these in influence for good.

In all this there is no sign whatever of any lack of application of science to industry. In industry, in the attainment of comfort and science and invention we are alike successful. Germany is also successful because she shares the results with ourselves of the work of the whole world, but she shows no signs of success in the least likely to overcloud England. Our professors, in my view, are entirely mistaken. They see a successful Germany; they imagine her more successful than she is. They see an unsuccessful England simply because they have failed to take a broad view of the whole position. Tested by results, England is successful both in industry, science, and invention.

The inevitable conclusion we arrive at is that England compares to great advantage with Germany in all the arts of peace.

How do we compare in war?

England has in the past been engaged in many wars. The result is evident in our huge Empire, the greatest which the world has ever seen; great sister dominions governing themselves, controlling huge tracts of country, and having populations of British and their descendants of about 16 millions external to these islands. We also have Crown Colonies and huge Dependencies, such as India, Ceylon; Protectorates, such as Egypt. In fact, the British Empire exists in Europe, Asia, Africa, America, and Australasia, with a population of more than 400 millions, and a total area of over 13,000,000 square miles.

British methods of governing have hitherto enabled us to maintain this huge Empire in security with a total army of about 700,000 men all told, including territorials and reserves. The geographical fact of the British being an island race led to an empire spread over the seas of the world, and made it necessary to maintain a great fleet.

Our small army provoked German contempt; our fleet, German admiration and rivalry.

German reasoning is very curious. They thought that a nation with so small an army had no right to exercise dominion over one-fifth of the world. They felt strongly that right could only exist when accompanied by huge physical power in the shape of a great military system. The freedom of our colonies and our dependencies was entirely misunderstood by them. They felt that all were longing to liberate themselves from the British yoke. They thought that at the first breath of war Australia, Canada, New Zealand and South Africa would rebel, and that India would rise against our small army and annihilate it. They failed to understand that the freedom of the governed formed an essential part of the British method of ruling. In these islands, in her colonies and in her dependencies government was so arranged by England as to reduce interference with the liberties of the people to the absolute minimum. Governing was always arranged as part of the English system in the interests of the governed. The portion of the world ruled from England experienced prosperity such as had never been known before. Accordingly, when the great war broke upon us last year, Germans were astounded to find that from all the world over help in men, money and munitions was at once lavishly forthcoming. Australia, Canada and New Zealand sent strong contingents of their best men. India and Indian princes were eager to fight for England. Only in South Africa did Germany succeed in raising a comparatively insignificant rebellion; and even here they were astounded to find that Britain withdrew all her troops and left General Botha with his loyal followers to deal with their domestic concerns. The result we have seen. Not only did the rebellion subside in the Commonwealth of South Africa, but the South Africans themselves vigorously proceeded against German South-West Africa, and speedily reduced it to subjection.

Whatever England's moral virtues are, her supremacy has proved to be anything but an unreality. Whatever her moral virtues are, her political power has proved to be anything but an arrogance and a pretence. The German idea of the British position proved to be absolutely wrong.

The German rivalry in fleet building lasted for many years, but England followed improvement with improvement; a continuous increase in tonnage of our war vessels, stronger armour, larger guns and enormously increased motive power. Strain as the Germans might with all their science and method, they utterly failed to keep pace with Britain. When they were building battleships with 11-inch guns, ours had 12-inch; when they attained to 12-inch we had 13½-inch; and when they attained to 14-inch guns we presented them with a fleet

having 15-inch guns. At first Germany tried to persuade herself that her smaller guns were superior to the larger British, and that in some way her mechanism was better and her sailors more completely trained. In motive power as well as guns and ships they also followed England. Sir Charles Parsons succeeded in applying the steam-turbine to ships in 1897. The English Admiralty soon came to the conclusion that battleships not only required powerful armour and large guns, but higher speeds than were obtainable by reciprocating engines. The Parsons turbine gave power within limits of weight which made very high speeds possible. Accordingly England had battleships with over a million horse-power in steam-turbines afloat before the slow movement of the German brain grasped the fact that turbines were better than reciprocating engines.

This was also true of our merchant fleet. England had about half a million horse-power in steam-turbines aboard her merchant fleet before the Germans had a single merchant turbine vessel. Germany signally failed to keep pace either with shipbuilding, guns, armour, or engines as found in the British fleet.

Before the war, because of such utterances as those of Lord Charles Beresford, many doubted the power of the British fleet, and Germany often proclaimed it over-rated, and even German officers drank to "The Day" when the battleships of Britain and Germany would meet in the final great trial. After fifteen months of war the relative positions of Germany and Britain in the world prove the overwhelming strength of the British fleet; the German battle fleet locked up in the Baltic and the Kiel Canal; the German mercantile fleet swept entirely off the seas; no single German cruiser afloat to harass British commerce; the British flag supreme upon the seas; and British commerce proceeding in its normal manner in all the seas of the world. The German admission of Britain's overwhelming strength is here complete. They do not share Lord Charles Beresford's views as to the illusion of the "Dreadnought" policy, although they may agree with him that Great Britain has become, so far as Germany is concerned, the "Bully of the Seas."

The British navy is as efficient in her battle cruisers, light cruisers, torpedo destroyers and submarines as she is in the battle fleet. Contrary to the idea assiduously circulated by Germany, Britain took the lead in submarine construction, and at the beginning of the war Britain possessed many times the number of submarines existing in the German navy. Britain's torpedoes, too, were of a very powerful and efficient type, developed—again in Britain—by British officers of the Royal Naval Torpedo Factory to a power and speed greatly in excess of those of the German torpedoes. Undoubtedly in war our naval results are superior to those of Germany.

With regard to the army, Germans failed to see that, given a sufficiently powerful navy, Great Britain had ample time to produce a numerous and powerful army. It is true that at first Britain had prepared only a small army; and at first, as Mr. Asquith has said, she sent over to the Continent in a few weeks some six divisions—about 120,000 men; but in doing this she amply fulfilled all her promises to her Allies. It speedily became evident, however, that the Allies stood in need of greater assistance than this; but the difficulty arose, not because of any defect in Britain's preparations or in the fulfilment of British promises, but on account of unexpected difficulties found by our gallant Allies in developing their full strength. British resource and elasticity enabled us to go rapidly to their assistance; and now, as Mr. Asquith has told us, Field-Marshal Sir John French has nearly one million men fighting on the western front, and we have large armies, safely transported by our ships and protected by our cruisers, in the East, all fighting vigorously.

Britain is successful, even on the military side, to a degree which surprises Germany.

So far Germany has been entirely unsuccessful. It is only necessary to glance at the extracts reaching England from the German papers in the early days of the war and to read Bernhardi's work to see how different this war is from that planned by the German Emperor and his great General Staff. The original idea undoubtedly was rapidly to overwhelm France by violating the neutrality of Belgium, and then to turn on Russia before she had time to mobilise fully. The German idea was definite on this point, and Bernhardi lays special emphasis on the rapidity of movement. "France," he says, "must be so completely crushed that she can never again come across our path." Six months seemed to be the extreme period set by them for this work. Britain was not intended to fight at all, and the British intervention, by Britain's secure grip on the seas, nullified all Germany's elaborate preparations.

Germany has lost millions of men and has not succeeded in one of her objectives. Even at the present moment England is successful in war; we have only to exercise patience and stand firm

to see the final collapse of the enemy. In war, as in peace, judged by success, England's methods are not inferior to those of Germany.

Why, then, does Germany, with its order and method, fail in war, while "unpractical, illogical, idealistic England" is successful?

The cause, I believe, is to be found deep down in the nature of the respective peoples. The German brain is, according to Buckle, deductive, while the English brain is inductive. All German philosophers have invariably been of the deductive type, while among English philosophers only Newton and Harvey are deductive. Practically all others are inductive. The deductive brain, allied to stupidity and a curious irrelevance, is characteristically German, and often produces absurd results. Even when legitimately used the deductive system is dangerous. It looks far more orderly and brilliant to deduce a whole universe from a few general propositions, but in actual life it is much safer and more accurate to rise from the particular to the general rather than to descend from the general to the particular. Darwin's brain was essentially inductive. He amassed numerous facts; he reasoned at short range from those facts, and ultimately established general propositions after much study and examination of apparently trifling matters. The inductive system treats formal logic with contempt, and this is characteristic of the English intellect. In science Faraday was eminently inductive. He always accumulated a great mass of experimental facts, and reasoned from them at short range to some general principle which he found underlying all the facts.

The inductive method may be said to be essentially an experimental method. English inventors have been almost invariably inductive. James Watt and his colleagues produced splendid and powerful steam-engines, working with an economy admirable for the time, without a knowledge of the mechanical theory of heat. No professor or scientific man could have given them that knowledge, because it did not spring into existence during Watt's lifetime. Notwithstanding ignorance of the great general principles, by diligent experiment, reasoning from experiment close to his facts, and summing up all his reasons, he developed on true lines. The science of thermodynamics did not create the steam-engine. On the contrary, it may be truly said that that science originated in the study of steam motive power.

English science is still essentially inductive, although after a certain stage induction and deduction are powerful aids one to the other. The inductive method looks disorderly. It is a method of trial and error, but more solid knowledge has been gained by its use. It looks unmethodical because the mind is confused by a multitude of facts. Ultimately, however, after sufficient care has been devoted to the study of the facts, it becomes methodical in a safe manner. The inductive method is a method particularly suited to the limitations of the human brain. The deductive method requires an accuracy of postulate or premises in most cases beyond the range of the human intellect. In some cases the method gives brilliant results, as in Adam Smith's treatment of "The Wealth of Nations" and Poincaré's treatment of the "Theory of Explanation."

Mathematical studies deal eminently in deduction, but most practical affairs, although guided by mathematical considerations, are too complicated to be fully treated mathematically. Some simplification is always necessary before it is possible to find a formula to fit the usual complication of facts occurring in engineering. Continental mathematicians and physicists always smiled while they admired the inductive intellect of Lord Kelvin, who at one time said that he never considered he understood a theory unless he could make a model illustrating its action. This making a model of everything is characteristically English, and safe. The model permits us to see incongruities and departures from simple theory. The deductive intellect tries to strain matters—and, indeed, human affairs—into a rigid frame, granting only general propositions and deducing all the rest from these. The Germans as a nation always tried to do this. They must have formal order. They must think out a complete system, all the parts flowing one from the other, all co-operating in different ways to produce the desired result.

The whole German nation is moulded upon the military idea of power and the rights of nations determined by power alone. It is a simple-minded and foolish idea, which entirely misses the unknown occurrences and forces easily discovered by inductive methods. It gives an apparent simplicity and order to real disorder. Life is infinitely complex, and the human intellect is too feeble to grasp all life in one simple ordered sequence. Germans attempt this and they fail. The English realise the truth. They have no illusion about the mightiness of their intellect. They do not say, as a German says, "This should, or must, act in this way"; they ask, "Here are circumstances; what is

really happening ?" They observe the circumstances, and they deal with occurrences largely as they present themselves. The English always grasp, however, in war as in peace, the essentials which must be observed if failure is to be avoided. The Germans sometimes succeed in their ordered sequence, but Nature interferes most rudely and prevents the accomplishment of things which German reason proves absolutely to its own satisfaction should really follow. England grasped the main facts of its existence protected by water and an industrial population needing large supplies of food from outside; hence an overwhelming navy, and behind the "sure shield" of the navy she knew she would have time, whatever arose, to plan, devise, and meet difficulties. In this great war she is doing that, as she ever did. All the appearance called unpractical, illogical, or muddling through, is but appearance. England is not unpractical. She is the most practical nation in the world. She is not formally logical, but she is idealistic, her ideal being that of freedom for her sons and for the whole world of nations, small and large alike.

After delivering the address, the Chairman presented the Society's medals which were awarded for papers read during last Session.

At the Ordinary Meetings:—

Sir William A. Tilden, D.Sc., F.R.S., F.C.S., "The Supply of Chemicals to Britain and her Dependencies."

William A. Young, "Domestic Metal Work of the Eighteenth Century."

J. A. Hunter, "The Textile Industries of Germany and of Great Britain."

Hon. John Collier, R.O.I., "Portrait Painting: the Technique of the Great Masters."

Professor W. J. Ashley, M.A., M.Com., Ph.D., "The Economic Position of Germany."

Horace M. Thornton, M.I.Mech.E., "The Industrial Uses of Coal Gas."

A. S. E. Ackermann, B.Sc., Assoc.M.Inst.C.E., "The Utilisation of Solar Energy."

Charles Darling, A.R.C.Sc.I., F.I.C., "Recent Progress in Pyrometry."

In the Indian Section:—

Captain Sir George Duff Dunbar, Bt., "Tribes of the Brahmaputra Valley."

Lieutenant-Colonel A. C. Yate, "The Indian Army."

Perceval Landon, "Basra and the Shatt-ul-Arab."

Sir Charles H. Armstrong, "Indian Trade and the War."

In the Colonial Section:—

Major E. H. M. Leggett, R.E., D.S.O., "The Economic Development of British East Africa and Uganda."

Edward R. Davson, "Sugar and the War."

For Special Lecture:—

Paul Lambotte, Directeur des Beaux Arts au Ministère des Sciences et des Arts de Belgique, "Constantin Meunier et les Sculpteurs Belges de son Temps."

Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., in proposing a hearty vote of thanks to the Chairman for his very able address, said it was not usual to discuss the subject-matter of the address at the opening meeting of the Session, but on the present occasion he was sorry that was not the custom, because many gentlemen were present at the meeting who could have added most useful commentaries to what the Chairman had said. To his mind the address had been a most clear and useful epitome of the material position in science, industry, and commerce, as between Germany and this country, and it ought to be most widely circulated. In particular, he would like every Member of Parliament to have a copy of it. Enough had been heard, at any rate, for the Fellows to congratulate themselves that so able a scientist as Dr. Dugald Clerk had kindly consented to be the Chairman of the Society for the present Session.

Mr. Charles Hawksley, M.Inst.C.E., in seconding the motion, said the Chairman's address had been most reassuring, and he hoped that not only the members but many others would take it to heart. He had clearly shown that England was not so much behind Germany as they had been apt to think, and he had proved that in many things she was actually ahead of her. He hoped that view would be widely spread, because there was a tendency not to give sufficient importance to what was done by scientists and other workers in this country.

The motion was put to the meeting by Sir Thomas Holdich and carried unanimously.

The Chairman having briefly acknowledged the compliment, the meeting terminated.

SUBMARINE OIL PIPELINES.

In the course of a paper on "The Petroleum Industry of Mexico," recently read before the Institution of Petroleum Technologists, Mr. P. Charteris A. Stewart gave an interesting account of the way in which large oil-tankers are loaded with oil while moored some distance out at sea.

Owing to the unfavourable nature and the comparatively shallow water close in to the coast, the Mexican Eagle Oil Company originated the idea

of laying submarine pipelines to points where the largest tankers could be conveniently moored for loading purposes at any state of the tide and weather.

They have three deep-sea loading berths at Tuxpam Bar, with duplicate pipelines to each berth; the Penn Mexican Fuel Company also have two loading berths equipped in the same manner with pipelines in duplicate.

The first two lines were laid by the Mexican Eagle Oil Company for the loading of the Oil Fields of Mexico Company's oil in March, 1910; these were six inches in diameter, and respectively 3,608 ft. and 5,150 ft. long below high-water mark. After being hauled through the breakers, these lines were continued into deep water by laying from barges, which was slow, costly and unsatisfactory work, as on reaching deep water the pipe developed bends in laying.

In view of the experience obtained with the first two six-inch sea lines, the succeeding eight-inch lines, each 5,150 ft. long, laid in 1911, were screwed up completely on shore on a carefully prepared wooden track twelve inches wide, at right angles to the shore, and directly in line with its permanent location. The pipe was mounted on small wooden trolleys, each running on a single roller; the trolleys were lashed to the pipe at alternate joints. The trolleys were removed during launching by cutting the lashings when they reached the end of the runway, allowing the trolleys to fall into a pit, from which they were removed as the hauling out progressed.

One hundred and thirty trolleys were used, each taking a weight of 1,277 lb., or two lengths of pipe. After screwing together, the end of the pipeline was closed by a bull plug, and the whole line coated with Texaco dip applied hot and spirally wrapped, like puttees, with burlap in strips twenty inches wide, after which another coat of Texaco dip was applied hot as before.

Uprights with vertical rollers were placed as guides at the water's edge on either side of the runway. An inch and a quarter steel cable, 1,750 ft. long, was made fast to the end of the pipeline, and taken out to a 3,000-ton steamer ("San Cristobal"), which was used as a tow-boat. In one instance this cable was taken out overnight, and, before hauling out commenced, got carried somewhere to the south and sanded over, so that the first pull was not in the true direction, and the necessity of the guide-posts was demonstrated; as a rule, however, after making the initial pull by means of her windlass on anchors previously laid ahead, the steamer had no difficulty in keeping on her course and towing out the line, at the rate of three to four miles per hour, to within a few feet of the buoyed position, the steamer towing the pipeline being attended by a tug to keep her bows in the correct course and correct any tendency to drift with the current, the slow speed of the towing not being sufficient to give the steamer steerage way.

The lines terminate in 43 ft. of water, which is below wave-action, and at the point where the iron pipe ends, 120 ft. of armoured flexible hose was attached by divers. The free end of the hose is closed by a blank flange, and allowed to lie on the sea-bottom when not in use, its position being marked by a small buoy attached to the hose by a chain sufficiently strong to lift it.

The rise and fall of tide is approximately two feet, so that the depth of water, 43 ft., is sufficient for the largest tank-steamers to load at any time; tankers of 15,000 tons dead weight drawing 28 ft. are regularly loaded.

Vessels loading come into position and moor to the permanent buoys, and are assisted, when required, by a tug of 1,000 horse-power permanently stationed at Tuxpam. After mooring, the tank-steamer picks up the marking buoy with the most conveniently situated of her own derricks, and raises the flexible hose alongside the vessel's rail. The hose is attached to the vessel's own loading connections, usually amidships, the weight of the hose remaining on the vessel's derricks.

The necessary control valves for the various lines are on shore, and are so arranged that any loading pump can be used on any line, or two pumps can be used to load one vessel. The loading station comprises three pump units, each of a capacity of 1,500 barrels per hour, or a total loading capacity of 4,500 barrels per hour, the pumps being suitably designed for handling heavy crude oils. They are triple-expansion, duplex, condensing, and can work up to a pump pressure of 450 lb. per square inch. Steam is supplied by the water-tube boilers, and the station is run continuously, allowing loading to proceed at all times.

With the code of signals in force between the pumping station and the vessel, it is possible to load the largest steamers in almost any weather, only fierce northers (75 kilometres per hour) occasionally interfering with loading operations.

As a rule it takes about twenty-four hours to load one of the large 15,000-ton tankers of the Mexican Eagle Oil Transport Company, which is equivalent to a loading rate of about 4,375 barrels per hour.

POTASH IN SPAIN.

For some time past potash deposits have been known to exist near Barcelona, and borings and analyses have been repeatedly made in the region where the salts are found in the provinces of Barcelona and Lerida. According to a report by the United States Consul-General at Barcelona, the results have been particularly favourable, but it will require the employment of capital and enterprise to make potash in this region a commercially profitable product.

In the various borings near the town of Sarria, potash salts were found at depths between 121·33 and 196·85 ft. and others at 426·50 ft. At 885·82 ft., the greatest depth attained, important quantities

of potassium compounds were found to rest on a stratum of white salt not yet pierced. In the area tested by borings comprising some 2,690,000 square ft. there are approximately 2,550,000 tons of carnallite and 1,150,000 tons of sylvite, which should produce a total of 3,675,000 tons of potassium salts.

From the general characteristics of the region it is considered probable that there are further deposits in greater or less proximity to those already tested. In a stream running by the salt works of Cardona there is a large percentage of potash in solution, and it has been discovered that vast quantities of potash have already been allowed to go to waste in the salt mines that might have been profitably used.

On account of the exceptionally irregular geological formation of this particular part of the country near Barcelona it is difficult to make exact valuations of the amount of potash salt that can be mined. Nevertheless, the presence of certain gypsum beds and the potash-holding streams will serve as a guide to determine the continuation of the potash deposits.

Particular interest has been displayed in these potash deposits by non-Spanish capitalists. One large tract is already owned outside of Spain, but in view of the great national importance of the deposits the Spanish Government are taking measures for their supervision, if not for their exploitation.

At the present time the amount of potash used per square mile of cultivated land in Spain is very small compared with that used in some countries. Nevertheless, fairly large imports of potash have been made in Spain, and it would be greatly to the advantage of Spanish agriculturists to use the domestic product, which it is calculated could be sold at about £10 a ton, or £5 a ton less than the cost of the imported product of the best grade. Since the beginning of the war, imports of potash have practically ceased. When the product now latent near Barcelona is brought to the surface and made a marketable commodity, there should ultimately be a surplus for export after the home requirements are satisfied. For the time being, however, in spite of a great outside demand, there can be no export of potash mined in the country.

GERMAN SUBSTITUTE FOR JUTE AND HEMP.

In view of the scarcity of jute and hemp in Germany for industrial purposes, German manufacturers have been directing their investigations along various lines in an effort to discover, if possible, some practical substitute for these fibres. That they have been successful in these endeavours would appear from a report of the recent meeting of the Union of German Jute Manufacturers, at which various samples of fibres from a German plant (*Epilobium hirsutum*) were submitted.

According to a report on the subject by the United States Consul at Breslau, this discovery was partly due to an accident. It appears that a man had used this plant as a roof-covering for a cart-house some years ago. Recently, in removing this old roof, he found that a certain rough hair-like fibre could be peeled off the stems or reeds. After a number of experiments with a quantity of these fibres it was further discovered that, on account of their age and the effects of the weather, they were too brittle for practical purposes; so several plants of this year's growth were tried, with the result, says the Consul, that another useful and practical textile fibre has been discovered.

Further investigations were made with other species of the *Epilobium* family, and it was found that all of them produced a fibre similar to hemp. The best results were obtained from the rough-haired willow rose (*Epilobium hirsutum*), followed by the narrow-leaved species (*Epilobium angustifolium*). All of these grow wild and in great abundance in Germany. The two species just mentioned have stems about 5 ft. in length, require no particular soil, and produce a fine fibre. It is believed that by attentive cultivation a fibre as valuable as jute may be obtained.

There are sufficient quantities of these plants in Germany to supply the jute manufacturers with fibres for a year, and the only question which confronts the manufacturers is that of gathering in the crop. For this purpose school children were to be employed during the holiday season, Government officials having promised to aid in the systematic organisation of these young harvesters. The Union of Manufacturers will give, it is stated, every encouragement to the further cultivation of this plant.

FLAX FIBRE IN THE UNITED STATES.

The common impression that flax fibre of a sufficiently good quality cannot be produced in the United States is declared to be quite unfounded in a new publication of the United States Department of Agriculture—Farmers' Bulletin, 669. "On the contrary," says the Bulletin, "it has been demonstrated beyond all doubt that fibre flax of excellent quality can be grown in various sections of the United States." Experiments, for instance, have shown that fibre flax from Puget Sound compares very favourably with that produced in the famous flax region of Courtrai (Belgium), and fibre of good quality has also been grown in Minnesota, Wisconsin, and Michigan. Weather records show that the temperature and humidity in the principal flax centres of Europe are much the same as those which prevail in certain sections of New York, Michigan, Wisconsin, Minnesota, Oregon, and Washington.

Nevertheless, there is a belief that the growing of fibre flax—a very different thing from the growing of flax seed—cannot be successfully carried on in America. As a matter of fact, at the present time it cannot be, but this is entirely because of

market conditions. The individual farmer can grow fibre flax, but he cannot prepare the fibre. Flax farmers, of course, could unite to pay for an experienced man to attend to this work for them, but under present conditions it would seem better for them to grow their flax under contract with the dealer. In the past, however, spinners and manufacturers have paid little more than half as much for American fibre as for the imported varieties of equal grade. In consequence, the fibre dealers cannot offer the farmer a high price for his product.

On the other hand, the production of flax fibre in Europe has been decreasing for some time, and at the moment the supply is practically cut off. It probably will be several years before the European production is as great as formerly, and it appears, therefore, that the present moment offers opportunities for the establishment of the industry in the United States.

During the past three years the prices paid to the farmer for flax straw with the seed, drawn directly from the shock, have varied from 10 to 17 dollars (£2 1*s*. to £3 10*s*.) per ton, and the yield has been about two tons of unthreshed straw per acre. The grower usually receives from 2 to 3 dollars (8*s*. 3*d*. to 12*s*. 4*d*.) more for pulled flax than for cut flax, and there is also a larger crop when the flax is pulled, thus saving all that would otherwise be wasted as stubble. Up to the present, however, no satisfactory pulling machine has been made, and, except where labour can be secured at a comparatively low rate, cutting the flax with a grain binder appears to be the more economical method in the United States. In Europe the usual method of harvesting is by hand-pulling. This not only increases the quantity of the crop, but prevents the fibre near the cut ends of the straw becoming discoloured or otherwise injured.

It is, however, after the straw has been harvested that the real difficulties begin. The preparation of fibre from the straw requires technical knowledge and skill, and can safely be undertaken only by those who are experienced in the work. For this reason the Bulletin referred to above urges prospective flax growers to make arrangements with dealers for marketing their product, or else by means of co-operative associations to secure the services of an expert.

PAINTING AND PREVENTION OF RUST.

The *Zentralblatt* draws attention to a series of experiments conducted by Liebreich and Spitzer to determine the effect of the number of coats of paint on the rate of rusting of iron. They polished four iron plates and painted them—the first with one coat, the second with two, the third with three, and the fourth with four. The plates were then exposed to steam for one day. The paint was dissolved off and the following distinct results noted:—

The iron under the single coat was bright all over, that under two coats was partly rusted, that under three coats rusted still more, while the iron under the four coats was covered with rust. This experiment shows that several coats of paint do not protect as well as one coat.

The explanation of this is that subsequent coats of paint or varnish tend to dissolve part of the previous coat. This has the effect of loosening the previous coat and making it porous, the porosity increasing with the number of coats. Air and moisture penetrate the pores and the iron below is rusted.

Where rust is feared, the coat of paint or varnish is usually made too thick, and the application of a second and third coat naturally does no good. The proper procedure is to remove all old paint by using the sand blast, solvents, etc., and then give the clean iron surface a single coat of the paint or varnish.

ARTS AND CRAFTS.

Women Home-Workers.—It seems to be inevitable that at this time of year the function of the artistic crafts which is most conspicuous should be the production of small objects suitable for presents. People do not refurnish or redecorate their houses as a rule in midwinter; they do not often put up stained glass windows at a time when, in our climate, there is little chance of seeing them in their full beauty. Big and important works of any kind are rarely exhibited in November and December, and the shops, with the exception of the jewellers and silversmiths and the booksellers, wait to show their more imposing wares until the days are beginning to lengthen. On the other hand, the approach of Christmas brings hope and opportunity to a host of home-workers in the artistic crafts, and to the growing class of semi-philanthropic organisations which provide work for the crippled, the mentally deficient, the blind, and those debarred for one reason or another from entering the labour market on quite the ordinary terms. One cannot help wondering what effect the war will have in the long run on undertakings of this kind; it would seem as though, in view of the increased taxation which we must expect, they might have to modify their working to some extent. It is, at any rate, to be hoped that they will be able to weather the difficult time which must lie before them. The case of the home worker is, perhaps, somewhat different. She (it is generally a woman) produces mainly luxuries which, though people in the past have been able to afford them, will not probably be much in demand in the years that are coming. Meanwhile, the shortage of men is giving many women their chance, and those who are not pre-eminently successful in their craft would, especially if they are young and unfettered, do well to consider whether they would not be well advised to turn their attention to some form of work in which they were helping to provide something that

people cannot do without. Many people (particularly women) appear not to grasp the fact that the spending power of the greater part of the well-to-do classes is going to be curtailed, not merely for the next few months or whatever limit they put to the continuance of the present struggle, but for some considerable time after, and that never again will conditions be just as they were before it began. That there will be room for a certain number of thoroughly well-equipped and competent women art workers who are also capable organisers, we all of us hope and believe, but it looks, to say the least of it, doubtful, whether in the domain of the artistic crafts there will be any place for women of lesser power, unless they are willing to take industrial posts, and to train as trade workers rather than as artists or artist-craftswomen.

Disabled Soldiers and the Artistic Crafts.—The exhibition and sale of Christmas toys and other objects made in the Lord Roberts' Memorial Workshops, which was held at Prince's Skating Club at the end of October, did not pose at all as an art exhibition. Its aim was to make known the work being done by our wounded soldiers, and to find a market for some of the work already executed. But the objects shown had for the most part some artistic interest. They consisted mainly of toys and baskets, together with furniture of a fairly simple type. The last was for the most part rather amateurish—it takes time to train even a sound man as a joiner and cabinet-maker—but the work was, on the whole, very promising. The baskets were of many kinds and their execution varied enormously. Some of them were really beautifully made, and the shapes were for the most part simple, sensible and good. There was very little of the fussy kind of product known as the fancy basket, and the majority of the exhibits would have unobtrusively held their own in the positions they were meant to occupy. The gilded baskets were rather garish, but with that exception there was very little fault to find with the work viewed as the output of men who were learning their trade and not past masters of it. The toys require rather more notice. Most people are determined that never again shall the overwhelming majority of our toys be imported from Germany, and there is a growing feeling that the toys of the future must be more beautiful than those of the past, better that is to say in colour and in form, and, in the case of more expensive toys, more individual. War economy is not likely to be allowed to take the form of depriving children of their toys, and it had been demonstrated long before this war that disabled soldiers and sailors could make wonderfully attractive wooden animals and the like, which rejoiced the heart not only of children but of parents, and bore evidence of having given pleasure as well to those who made them. Toymaking, therefore, suggests itself at once as an excellent trade for wounded soldiers, and the exhibition at Knightsbridge showed that those responsible for Lord Roberts' Workshops had realised the fact. Some of the most desirable toys, such as cannon, monitors and torpedo boats, did not leave very much scope for art, but the forts were a great improvement on the old imported ones, and the fairy stories, Cinderella, Jack the Giant Killer, Puss in Boots, and the rest, in which the lid of the box acted as a kind of drop scene and the principal characters were cut out and mounted on little wooden stands, so that they could be moved about at will and made more or less to act the story, were not only a happy thought but evidently conceived and controlled by someone with real artistic feeling. The toys as a whole, though not of course works of art exactly, were up to a standard of taste which was certainly not reached a couple of years ago. The prices were naturally a little higher, but they were by no means exorbitant. There were good toys to be had for a shilling and five shillings, though it was perhaps rather more difficult to find what one wanted at the popular price of half-a-crown. The exhibition, however, was a very good one, and augurs well for the success of the workshops.

Embroidery at Westminster.—The Needlework Competition of the *Daily Sketch* attracted an extraordinary number of competitors, and the exhibition held at the Central Hall, Westminster, included plenty of really good embroidery, some of it employed to excellent artistic purpose. There were over thirty classes, most of which were to do with lace and embroidery. For all that the show was, to the lover of art needlework, somewhat of a disappointment. In the first place, as the objects were mostly for sale, they had to be displayed in a fashion which made it rather difficult to study them. Further, the lighting of the Central Hall is not peculiarly well adapted to the exhibition of fine needlework, and it was almost impossible to judge of the stitchery of a good deal of the work. The visitor to the exhibition was, moreover, rather oppressed with the feeling that at the present moment there was no very insistent demand for important and expensive pieces of embroidery, and that the amount of energy which had been put into the production of the objects on view could just now have been employed to greater advantage. At the same time the work, especially in some of the classes, reached at times a high level of artistic and technical achievement, and it was both interesting and instructive to see so large a collection of artistic needlework of all kinds. The Church embroidery was a little disappointing, for while some of the smaller objects were tasteful and well executed, much of the larger work was mechanical in the extreme. There was a good show of tapestry and *petit point*, some good cutwork, and a great deal of satisfactory old English embroidery, but perhaps the most interesting section was that devoted to needlework pictures. The panel which took the first prize in this class was a beautiful piece of work, admirable both in treatment and in

stitching; but a considerable number of the competitors who sent in figure pictures had fallen into the error of attempting a type of pictorial representation quite beyond the powers of the needle. The landscapes were happier, and many of them were really attractive pictures in stitchery which had, one felt, been drawn with the needle, and showed no striving on the part of the worker to attempt the impossible.

Women's Work at Knightsbridge.—The Exhibition of Women's Work now being held at the Prince's Skating Club is an interesting show, but hardly perhaps justifies its sub-title of "an Exhibition of the Arts and Crafts of the Homeworker," for it includes very little of the work of the best women craftworkers. Its value on the arts and crafts side is mainly due to the fact that a number of guilds, societies, and associations are exhibiting. Amongst these may be noted Queen Alexandra's schools of needlework and of woodcarving at Sandringham, from which come exhibits covering a very wide field; the Dun Emer Guild, which makes a speciality of Celtic designs; the Barclay workshops for the blind, which show some admirable weaving, some of it in patterns; the Hampshire House workshop, whose exhibit of dressmaking and embroidery attracts by the brightness and freshness of its colour; and the Essex Handicraft Association, which sends, amongst other things, some good run lace. The war cannot be making it easy for undertakings of this kind to continue to extend their work, and it is satisfactory to see that they are doing their best to carry on, and in some cases adapting themselves to changed conditions.

OBITUARY.

Sir Patrick Playfair, C.I.E.—Sir Patrick Playfair died at his residence in Ennismore Gardens on the 12th inst.

The son of Mr. Patrick Playfair, of Dalmarnock, Lanarkshire, and Ardmillan, Ayrshire, he was born in 1852, and after being educated at Loretto and Glasgow University, he went out to Calcutta, and eventually became a partner in the mercantile and jute manufacturing firm of Messrs. Barry & Co. He was Vice-President and subsequently President of the Bengal Chamber of Commerce, which he represented on the Bengal Legislature. From 1893 to 1897 he served as additional member of the Legislative Council of the Viceroy and Governor-General of India, and he took an important part in the establishment of a separate Department of Commerce and Industry, with a member of the Viceroy's Executive at its head. He was sheriff of Calcutta in 1896, and was created a knight in the following year. He was also one of the organisers of the Victoria Memorial in Calcutta.

In 1899 he organised the first body of British Volunteers from India to fight beyond its shores, and it was largely due to the assistance rendered by him to his old friend, the late Colonel D. M. Lumsden, C.B., that Lumsden's Horse was raised.

Sir Patrick became a member of the Royal Society of Arts in 1898. He served on the Indian Section Committee from 1900 to the time of his death. He frequently attended meetings of the Indian Section, and occasionally took part in the discussions.

NOTES ON BOOKS.

Savage Man in Central Africa. By Adolphe Louis Cureau. Translated by E. Andrews. London: T. Fisher Unwin. 12*s*. 6*d*. net.

This is a book of remarkable scientific interest. The author lived for over twenty years in the French Congo, and during that time he devoted himself to a minute and careful study of the natives in that great region. For this task he had very special qualifications: he spoke their dialects, he lived their life, and, being endowed with a sympathetic and understanding nature, he thought their thoughts as far as is possible for a mind so unlike their own. The result is a wonderfully comprehensive and clear account of the Central African as he exists to-day, based entirely upon M. Cureau's first-hand observation.

The plan of the book is divided into three parts—the first describes the geographical and human environment of the French Congo; the second deals with the psychological individual as an element of social life; and the third with the social life itself. The French Congo covers an immense extent of ground, and the author had opportunities of studying the life of the native in all stages of its complexity, from the simple couple to the highest social organisations to be found in tropical Africa.

Some of the author's conclusions, as one might perhaps expect of one whose observations have been so careful and so extensive, are of the nature of heresies. For instance, he has no exaggerated opinion of the fineness of the black man's senses. "The negro," he says, "neither sees nor hears better than we do, even in the bush. He is simply more accustomed to the sights and sounds of his native land. It is the education of his senses, not their keenness, which enables him to distinguish game among the thick foliage or to recognise the distant summons of the war-drum. In this respect we are no whit inferior to him; indeed, we assert our superiority as soon as we have adapted our eyes and ears to the conditions of the African environment."

In this connection M. Cureau has some remarks on the value of psychological experiments, which may be commended to the attention of some of our present-day experimental psychologists. "Experimentation" [*i.e.*, in the case of the Negro], he remarks, "seems to me quite impracticable, if one wishes to obtain certainty and accuracy. Most of its processes demand that the

patient shall yield himself to them intelligently, and shall realise what is expected of him. You need hope for nothing of the kind from the Negro. I have often noticed how the clinical examination of sick natives is hindered by impediments due to the patients themselves. When one attempts to make them breathe, count, cough, assume certain positions, their awkwardness is so great that it reduces medical observation to purely objective indications, as in the case of children and animals. Hence we must be satisfied with the superficial observation sufficient for our present object."

M. Cureau has made a point of avoiding anecdotes which are merely picturesque. He does, however, tell one or two, which throw light on the Negro's psychology. Of these, perhaps, the most illuminating is a tale he relates to illustrate the fickleness of the native character: "The captain of a French steamer, who had put in at a village to buy provisions and wood, recognised, in a crowd which came running down to the river bank, a man who was a stranger to that district, and who had lately served as steersman on his boat. When questioned as to what he was doing there, the man replied that he was a captive in the village, and as such was destined some day or other to fill the cooking-pot of his masters. The captain thereupon offered to carry him off. He refused, because at the time he was enjoying all the luxuries of life, and the prospect of the knife had consequently no power to disturb him. The boat left without him."

Thanks to the author's easy style and the excellent translation which Mr. Andrews has provided, the book is extremely readable. At the same time it contains an immense amount of information, the fruit of twenty years' careful observation and study, and is a most valuable addition to anthropological literature.

Oil Seeds and Feeding Cakes. With a Preface by Wyndham R. Dunstan, C.M.G., LL.D., F.R.S. London: John Murray. 2*s*. 6*d*. net.

This volume contains the first series of monographs published by the Imperial Institute. The subjects dealt with are copra, palm kernels, ground-nuts, sesame seed, and mowra seed. Of these substances the first two have recently been brought prominently to the notice of stock owners as a result of the war. Formerly large quantities were exported to Germany and Austria-Hungary, but the closing of these markets has made it necessary for growers to find a new outlet for their products. In the case of copra, while a certain amount formerly came to Great Britain and France, the annual export to Germany and Austria was about 150,000 tons, valued at some £3,250,000. The situation was brought by the Imperial Institute to the notice of the principal British firms interested in copra, or likely to be so, with the result that the exports to London from Ceylon have risen from 1,500 cwt. in 1912 to 562,500 cwt. in 1914.

The story of the palm-kernel industry is very similar. Before the war Hamburg was the port to which practically all palm kernels were shipped, and the crushing or pressing operation was carried out there. The trade was a very large one, and a great proportion of the raw materials came from British tropical possessions—*e.g.*, in 1912 Germany received from British West Africa alone 250,000 tons of palm kernels, valued at £3,800,000. When the war broke out there was practically no market in this country for palm kernels, but a considerable industry has now sprung up, and, so far as British West Africa is concerned, the regular export of kernels to Great Britain has now been established. Both copra cake and palm-kernel cake are excellent food for cattle, the latter being particularly suited to milch cows, and the Board of Agriculture have published a special leaflet (included in this volume) in which the merits of both foods are described and analysed.

The great market for ground-nuts was Marseilles, where a very large industry was carried on in expressing oil and manufacturing cake. The latter was mainly exported to Germany, where its merits as a cattle food were well recognised; but since the closing of this market the Marseilles industry has fallen off, and there is now a great supply of ground-nuts to be disposed of. In addition to supplying a good cattle food, the ground-nut yields an oil which is useful in the manufacture of margarine, etc. It also has a further valuable property: it is a leguminous plant and possesses the power of fixing the nitrogen of the air, and rendering it available in the soil as a plant food, so that in the rotation of crops in the tropics, and especially in connection with cotton cultivation, the growth of the ground-nut is of great importance.

The principal use of sesame and mowra seeds is to provide edible oils. The first yields a well-known substitute for olive oil, and is most used in the manufacture of margarine; the second furnishes a fat much used for cooking by the natives of India.

There seems to be no doubt that the industries in connection with all these substances are capable of very great expansion, and the publication of this volume ought to do a great deal to establish them firmly in Great Britain.

English Railways: their Development and their Relation to the State. By Edward Cleveland-Stevens. London: George Routledge and Sons, Ltd. 6*s*. net.

The object of this book (which forms No. 42 in the series of monographs by writers connected with the London School of Economics and Political Science) is to present a detailed historical account of the consolidation of English railways up to the year 1900. Considering the enormous importance of our railway systems, and the vast interests which they represent, the amount of general literature on the subject is surprisingly small, although official records (*e.g.*, Parliamentary Papers, Hansard's Debates, Reports of Inquiries, etc.) and periodical literature (*e.g.*, railway newspapers and pamphlets)

are voluminous. The student of railway history will, therefore, be indebted to Mr. Cleveland-Stevens, who has produced from this heterogeneous mass of material a well-digested and methodical account of the evolution of English railways. Some idea of the labour involved in tracing out this development may be obtained from the statement that our present systems are "the consolidated outcome of more than a thousand separate companies of earlier days." The same idea is also graphically conveyed by two maps, showing the railway systems of 1848 and those of the present day, in which a short mileage under many companies is contrasted with a long mileage under the control of few.

Throughout the book Mr. Cleveland-Stevens plays the part of the impartial historian. He regards a knowledge of the past history of railways as a necessary preliminary to the intelligent study of the problem of their control in the future. The lines on which that problem is to be solved do not, of course, come within the scope of the present volume; but from the accounts given of the suicidal competition and inadequate services of small companies, it is not very difficult to guess something of the direction in which, in the author's opinion, they ought to develop.

GENERAL NOTES.

Water-power Development in Relation to Fisheries.—The construction of the great dam for hydro-electric power development in the Mississippi River at Keokuk, Iowa, has created, incidentally, the opportunity to study certain factors of importance to the conservation of river fisheries. The subject of fishways, which has attracted considerable attention from the engineering aspect, has never been studied adequately by biologists under actual field conditions. It is now officially announced, by the United States Bureau of Fisheries, that the bureau is conducting observations to supply the deficiency of information. The existence of a practical barrier in the river at Keokuk also affords unusual facilities for the study of fish migrations, and the creation of a large river lake above the dam probably will make feasible the development of important fisheries similar to those now conducted in Lake Pepin, a natural lake of generally similar configuration. As the conditions in the lake gradually assume permanency the loss of crops on the drowned farm lands should be compensated for in considerable measure by an increasing fish supply.

Production of Tanning Extract and Alcohol from Sulphite Lye.—The Norwegian *Farmand* states that an establishment for utilising the waste lye from sulphite pulp production is now being built at Embretsfos, near Drammen. The establishment will be ready to begin work in three months, and it is estimated that the production of tanning extract from the lye will be about 3,000 barrels per year. Also a factory for producing alcohol from the lye will probably be built in the near future in connection with a Norwegian cellulose mill.

The National Wealth of the United States.—The United States Bureau of the Census has just issued a bulletin, entitled "Estimated Valuation of National Wealth, 1850–1912," in which are given estimated values of the various classes of real, personal, and other property owned in each State and in the district of Colombia in the year 1912, with comparative figures for 1904 and earlier years as far back as 1850. The aggregate for the United States in 1912 was $187,739,000,000, which is equivalent to $1,965 per head. This bulletin has been prepared in connection with the Bureau's decennial investigation of wealth, debt, and taxation, and the statistics contained in it will later form a part of the final report upon that subject. These estimates are not presented as very close approximations to accuracy, but as being the best which can be made from the data available, and as being fairly comparable with those published eight years ago, relating to 1904. Copies of the bulletin can be obtained on application to the Director of the Census, Washington, D.C.

Formosa Sugar.—The latest official returns of the sugar-mills in operation in Formosa give the total of modern-style mills as 36, with a crushing capacity of 27,070 tons per day. There are also 39 old mills with a crushing capacity of 3,190 tons per day, besides 220 old native mills of unknown but small capacity. The area of fields under sugar-cane during 1914 was 215,198 acres, producing on an average (estimated) 14½ cwt. of sugar per acre. Early in 1915 shipments of refined sugar were made to Hong-Kong, which, however, were probably intended for re-export elsewhere. While the war doubtless gave an impetus to this export, it is only the realisation of hopes long existing, and efforts will not be spared to maintain a position in foreign markets.

Population of the Russian Empire.—The total population of the Russian Empire at the present time is estimated at 170,350,000, sparsely distributed over an area of 22,012,000 square kilometres (8,226,632 square miles). Of this, Russia in Europe, with a population of 137 millions, covers an area of 5,390,000 square kilometres (2,080,540 square miles), and Asiatic Russia, with a population of only 33,350,000, occupies 16,622,000 square kilometres (6,146,092 square miles). The number of inhabitants of the principal cities in order of their importance is: Petrograd, 1,911,000; Moscow, 1,505,000; Warsaw (before German occupation), 864,000; Odessa, 498,000; Kiev, 447,000; Lodz, 404,000; Riga, 328,000.

Germany's Food Supply.—Professor W. J. Ashley has followed up the admirable paper on "The Economic Position of Germany," which he read before the Society last February, with an article in the current number of the *Quarterly Review*. It is entitled "Germany's Food Supply," and in it the author deals with the food question at greater length than was possible in his paper, and with reference to later developments in the matter. A great many new facts are discussed, and the whole article deserves the close attention of all interested in the economic aspects of the war.

French and Flemish Books for Belgian Wounded.—The Comité des Visites aux Blessés Belges appeal for French and Flemish books in order to give to the Belgian wounded soldiers literature in their own language. About 3,000 volumes have already been received. These have been widely circulated, and it would be difficult to exaggerate the pleasure which they have given. But amongst the wounded are many students and technical workmen, who desire to follow up their studies, and for this purpose want books on science and engineering, chemistry, physical science, mathematics, mechanics, electricity and other sciences, and also commercial study books, technological works, etc. The Committee appeal earnestly for gifts of this kind, or for financial help which would allow them to buy such books. All parcels and letters should be addressed to Madame Carton de Wiarts at the Library Department of the Committee, Sardinia House, Sardinia Street, Kingsway.

The Professional Classes War Relief Council.—A great sale, which is being organised under the patronage of their Majesties the Queen and Queen Alexandra, will be held at the Royal Albert Hall on December 8th, 9th, and 10th. The Fine Art section will be devoted to pictures, curios and antiques of all kinds, and special appeal is made to those who have such objects in their possession, as it is felt that there are many who would be willing to give active and generous support by making donations to this section who would perhaps find it impossible to make the usual contribution. Gifts of every kind will be very gratefully received and acknowledged by the Gifts Secretary, Royal Albert Hall, London, who will be happy to answer any inquiries as to donations. A fund has already been raised to cover all expenses connected with the sale, and therefore the entire proceeds of the sale will go direct to the funds of the Professional Classes War Relief Council.

MEETINGS FOR THE ENSUING WEEK.

Monday, November 22...Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Mr. C. H. Hewitt, "Handwork on Negatives, including Knife-work."

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. Mr. E. M. Konstam, "Case Law under the Finance Acts."

Tuesday, November 23...Illuminating Engineering Society, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Discussion on the First Report of the Departmental Committee on Lighting in Factories and Workshops.

Sanitary Institute, 90, Buckingham Palace-road, S.W., 4.15 p.m. Dr. L. Parkes, "The National and Social Aspect of the Lower Birth-rate."

Royal Dublin Society, Leinster House, Dublin, 8 p.m. 1. Professor W. Brown, "The Subsidence of Torsional Oscillations and the Fatigue of Iron Wires when subjected to the Influence of Alternating Magnetic Fields of Frequencies up to 250 per second." 2. Mr. P. E. Belas and Dr. M. Hartog, "On the Path of a small Permeable Body moving with negligible acceleration in a Bi-polar Field." 3. Mr. T. G. Mason, "Preliminary Note on the Carbohydrates of the Musci." 4. Mr. J. J. Dowling, "A New Form of very high Resistance for use with Electrometers."

Photographic Society, 35, Russell-square, W.C., 8 p.m. Mr. H. Main, "Nature Notes near Home."

Zoological Society, Regent's Park, N.W., 5.30 p.m. 1. Mr. G. A. Boulenger, (*a*) "A list of the snakes of East Africa, north of the Zambesi and south of the Soudan and Somaliland, and of Nyassaland"; (*b*) "A list of the snakes of North-East Africa, from the Tropic to the Soudan and Somaliland, including Socotra"; (*c*) "Descriptions of a new Amphisbæna and a new snake discovered by Dr. H. G. F. Spurrell in Southern Colombia." 2. Professor A. Dendy, "On some Land-Planarians collected in Western Australia and Tasmania by members of the British Association for the Advancement of Science." 3. Mr. C. T. Regan, "The Morphology of the Cyprinodont Fishes of the Subfamily Phallostethinæ."

Wednesday, November 24...Royal Society of Arts, John-street, Adelphi, W.C., 4.30 p.m. Sir Edwin Pears, "Constantinople, Ancient and Modern."

Electrical Engineers, Institution of (Local Section), The University, Birmingham, 7 p.m. Professor A. B. Field, "Some Difficulties of Design of High-speed Generators."

Japan Society, 20, Hanover-square, W., 8.30 p.m. (Joint meeting with the China Society.) Mr. L. Binyon, "The Art of Asia."

Thursday, November 25 ... Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. J. H. Knight, "The Early History of Railways."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Professor A. B. Field, "Some Difficulties of Design of High-speed Generators."

Optical Society, Burlington House, W., 8 p.m. Mr. J. H. Sutcliffe, "The Influence of Visual Errors in Musketry."

Friday, November 26...Engineers and Shipbuilders, North-East Coast Institution of, Newcastle-on-Tyne, 7.30 p.m.

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

Saturday, November 27...Municipal Engineers, Institution of, 4, Southampton-row, W.C., 12 noon. Annual General Meeting. 2.30 p.m. 1. Presidential Address. 2. Mr. H. Boot, "The Manufacture of Cement." 3. Mr. W. L. Carr, "The Benefits derived by an Urban District adopting a Town-Planning Scheme."

Journal of the Royal Society of Arts.

No. 3,288. VOL. LXIV.

FRIDAY, NOVEMBER 26, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, NOVEMBER 29th, at 4.30 p.m. (Cantor Lecture.) WALTER ROSENHAIN, D.Sc., F.R.S., Superintendent, Metallurgy Department, National Physical Laboratory, "Optical Glass." (Lecture I.)

TUESDAY, NOVEMBER 30th, at 4.30 p.m. (Colonial Section.) SIR SYDNEY OLIVIER, K.C.M.G., late Governor of Jamaica, "Recent Developments in Jamaica: Internal and External." SIR HENRY A. BLAKE, G.C.M.G., will preside.

WEDNESDAY, DECEMBER 1st, at 4.30 p.m. (Ordinary Meeting.) THE MASTER OF CHRIST'S COLLEGE, CAMBRIDGE (Arthur Everett Shipley, Sc.D., F.R.S.), "Insects and War." SIR WILLIAM J. COLLINS, K.C.V.O., M.S., F.R.C.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

JUVENILE LECTURES.

Two of the Members of the Council—Professor John Millar Thomson, LL.D., F.R.S., and Mr. James Swinburne, F.R.S. — have kindly undertaken to deliver the Juvenile Lectures this year. Professor Thomson will give the first lecture on Wednesday afternoon, January 5th, at 3 p.m., his subject being "Crystallisation." Mr. James Swinburne will give the second on Wednesday, January 12th, at 3 p.m.; his subject will be "Science of some Toys." Both lectures will be very fully illustrated with experiments.

Special tickets are required for these lectures. They can be obtained, when ready, on application to the Secretary.

A sufficient number of tickets to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply for them at once.

PROCEEDINGS OF THE SOCIETY.

SECOND ORDINARY MEETING.

Wednesday, November 24th, 1915; COLONEL SIR THOMAS HUNGERFORD HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., Vice-President of the Society, in the chair.

The following candidate was proposed for election as a Fellow of the Society:—

Thain, James Edward Vyner, C.S.P. College, Exmouth, Devon.

THE CHAIRMAN, in introducing Sir Edwin Pears, said that he was really introducing the one man in all England who was best qualified to speak on the subject of Constantinople. His long residence there, and his practice as a lawyer, which brought him into contact with every class of society, his immense powers of observation, and, more than all, his literary ability, which had resulted in a most excellent history of the place, all seemed to bear out that view.

The paper read was—

CONSTANTINOPLE, ANCIENT AND MODERN.

By SIR EDWIN PEARS.

When I was asked to read a paper, or speak, on the subject of "Constantinople, Ancient and Modern," I had to consider what view I should take of the matter. Naturally, in an audience like this, there are people who do not know much about the subject, and there are undoubtedly experts, equal to any to be found in England; and, therefore, it seemed to me to

follow that what I had to say should be of a popular character as far as possible, but not losing sight of the great points which are of especial interest to us at the present moment.

Let us begin with Ancient Constantinople. I suppose everybody in the room knows that Constantinople was founded by the Great Emperor Constantine, and that on the official Name Day, 330, it received the name of New Rome. The Patriarch, as you are aware, signs himself to this day *Patriarchus novæ Romæ*, and has done so from that time to the present.

Now I am not going to attempt to give you any kind of history of the place throughout those years. I will take some of the brief periods during which Constantinople has written its name largely on the pages of time. We will pass Constantine altogether and go on to two centuries later, when we get to the period of, I think on the whole, the greatest Emperor that ever ruled in Constantinople—Justinian. I daresay that many of you—many of the ladies even—have read a good deal about him, especially his personal side. You all know his love for the beautiful actress Theodora, his constancy to her, his insisting on marrying her, and how she proved a very good wife. I think everybody admires that famous scene when, in the great riots that took place in the city between the liberals and conservatives, otherwise called the blues and greens, the whole city was in an uproar, and the two factions united with each other in order to get rid of Justinian. Then poor Justinian lost his head, as we men occasionally do. But the wife kept hers, and the speech she delivered on the occasion is one that comes rolling down the centuries with a fine message. "I have worn the Imperial purple. If we are to be captured and killed, well, the Empire's purple is a glorious winding-sheet. Let us fight it out!" And with the aid of the great generals, Belisarius and Arsenius, they fought it out, and Justinian was able to continue the work of his lifetime—and a wonderful work it was.

In the first instance Justinian is spoken of as a great lawyer, and he is responsible for what we Latins call Roman Law, meaning by that the law of the New Rome and not of the city on the Tiber. Those of you who are not lawyers can hardly imagine what an enormous effect the law of Justinian has had upon the jurisprudence of the world. There is not a civilised country in the world at this moment whose law is not saturated with the principles laid down in the time of Justinian.

Our own English law and, to a certain limited extent, that of Russia are the two which owe least to the legislation of Justinian, but if you ask any equity lawyer he will tell you that the principles on which our Courts of Equity act are all taken bodily from the Law of Justinian. Then, if he knows what he is talking about, he will tell you that the laws of France, of Italy, of Spain, of Belgium, and of a large part of Germany are simply the Codes of Justinian with slight modifications. So that this Emperor —and we must attribute the advantages of the change to the Emperor himself—gave law to the civilised world. Now, in addition to that, Justinian is spoken of as the great road and bridge builder, and perhaps for my present purpose that is his most convenient designation. Justinian the road maker and bridge builder is, I will not say more renowned, but equally renowned with Justinian the law-giver. Now what did he do in the way of road making and bridge building, and why did he do it? For the purpose of answering those questions I must ask you to listen to a matter as to which, on the only occasion when I have spoken on this subject since I was in London, I received several letters, the latest being received only yesterday. The history of the trade and commerce between the East and the West is always a fascinating subject and is one that in the course of the long existence of this Royal Society of Arts has, I am quite sure, often attracted the attention of the members. It used to be said with a certain amount of truth—certainly it was true until the year 1700 —that the nation which possessed the trade between the East and the West was necessarily the richest nation in the world. If you go back to really ancient history, say one thousand years before Christ, you will find that at that time Egypt, so far as the West was concerned, had a monopoly of the trade between the East and the West, the East standing for India and the countries beyond. The trade from Egypt to the East went at that time along three well-known roads: the first led from Egypt through Petra—which you all know by the beautiful photographs that have been taken during the last two or three years by the Society called the Palestine Exploration Fund. The ruins of Petra are extremely beautiful, and show that the city was at one time well supplied with water and was a really beautiful city. From there the road struck almost due east right across the Arabian Desert to the Persian Gulf. That was the first and the earliest great

road that we have between the East and the West. At the present time the road is absolutely impossible because there is no water in any part of it.

Then let us jump our periods of history to about a thousand years before the time of Christ—that would be the time of Solomon. The wise king of the Jews had the sense and the capacity and the ingenuity to divert the stream of traffic between the East and the West so that it should pass through his kingdom of Judea and so make him and his people rich. When that diminished, a second passage was established: it already existed in the time of Solomon, and was in full use at the time of Christ. That passed from Egypt along the Mediterranean coast in the country of the Philistines, Philistia as it is called, then took the valley through Judea —and if you had some of the beautiful relief maps of the Palestine Exploration Fund you would see the great natural depression that exists—and then struck due eastward, practically following the same road as was followed by the first road that I mentioned, which was already nearly out of use in the time of Christ. There was a third road which at that time was in full vigour, and came into still greater vigour during the next two centuries, which ran through Palmyra, or, as it is called in the Bible, "Tadmor in the Wilderness." I have not been to Tadmor, for when I was at Damascus, which is the nearest place to it, they said to me, "If you go you will die for a certainty," and I had not the slightest intention of dying at that time. It was a very hot season. The only water that exists in Palmyra is derived from a number of marshes in the neighbourhood which support a few wandering Bedouins. It is a deserted city. It was so entirely deserted that it was forgotten, and any of you who care to turn up in Bohn's Library the volume on "Early Travels in Palestine," will see there an account given by our chaplain at Aleppo, who took a party of colonists there. They went to explore these ruins—and superb ruins they are, though I only know them by photographs—and they then found that this mass of ruins was Palmyra. You may recall the fact that the famous Arab Queen, Zenobia, held court at Palmyra until she was defeated by the Romans.

These were the three great ancient roads that crossed the country and along which trade passed. There had already commenced in that part of the world a long period of drought; Arabia and Syria have for centuries—for millenniums, indeed—been liable to periods of alternate moisture and drought. You have got some proofs of that in the Old Testament. You remember the story of Jacob and Joseph, and of there being no pasture for the flocks, and of the people going down into Egypt to obtain provender for themselves and their flocks. That is an experience that has in the course of centuries been constantly repeated. After the time of Zenobia the districts to the south gradually became drier and drier. I could give you scores of illustrations as to how they became dry and as showing that they had dried up. For example, you all know that the Dead Sea is 1,300 feet below the level of the Mediterranean. It is below the level of the Mediterranean at the present time, but the old sea beaches that are around the Dead Sea show that at various times it has been very much higher. For example, Nazareth, which is now well up on the hills, was on the borders of the lake, and if you go farther north you come to the lake on which Capernaum and Gennesareth stood, which, in the time of Christ, were villages on the shores of the lake, but are now ruins on the hills. The water has receded. An old Russian monk, who visited the country about the year 1100, has a very poetical story that when Christ went down to the Jordan the waters fell back before their Lord and Master: that is his explanation of the water receding. However, we have nothing to do with poetry here, but plain matter-of-fact. The drying up of the country had enormously diminished the trade between East and West. Justinian saw that it might be recovered if roads existed between the Bosphorus, where he was reigning, and the Persian Gulf. Accordingly his first task was to make roads. We know where most of the roads were; some of them can be found very well in traces at the present time; along them there are the sites of cities that have long since been deserted, sometimes because the period of drought continued, sometimes on account of sheer pure misgovernment. I see in the audience two of my friends who know Smyrna better than I do, and from Smyrna there is a very charming expedition that may be made to Hierapolis. Now what is Hierapolis? In the first instance it was distinctly on one of these great Justinian roads. What is it now? What was it then? If you want to see what it was then, you can read a very fine account in Renan's Travels, and another, perhaps more practical, in those of my friend Sir William

Ramsay. In the first place, its position is superb. I know the Tyrol fairly well and Switzerland, but I know no valley that is more beautiful than that which the Smyrniotes call the Asiatic Switzerland. Amidst the great amphitheatre of hills there flow springs of hot water. I fancy the temperature is usually about 170° or 180° F. These well up from the ground and flow along the streets of an ancient city, and, depositing a certain amount of lime, have built themselves channels by the side of the street, where the water has been running for the last three thousand years, possibly longer. You can see the ruins of two enormous theatres, one of which we calculated would seat 30,000 people and the other 20,000. You see the ruins of churches and temples and especially of a large bathing establishment. The place had been knocked about considerably by earthquakes, but still you can see every indication that the city was once a wealthy city and well inhabited. What is it now? Who live in it now? A few gipsies, as useful and as useless as gipsies usually are. I speak of them as gipsies because they belong to the great families of Nomads. There is not a soul except these wandering Nomads who lives in the place. The waters are running as quietly and beautifully and making as beautiful terraces as they have ever done, but the place is a mass of ruins. That is one set of ruins on one of Justinian's roads, and one can hardly pass from that part of the world without remembering what Ephesus was. The best account that I have ever seen of Ephesus was written by Dean Farrar in his book on the Epistles of the Apostle Paul. He made a careful study of what the city was, and pictures a highly-cultivated and highly-civilised place, with half a million inhabitants. It is very wonderful and very interesting now to sit in the ruins of the very theatre that you read about in the Acts of the Apostles, where the great riot took place, the makers of the images of Diana fearing that their trade was going to be damaged by these new men who were preaching about a new God in the city. That, however, is apart from my purpose here to-day. This great city is now dried up. The quays, the wharves, are still there, and the iron rings along the wharves are not yet entirely rusted away. But it is naturally a scene of desolation.

We arrive at the point that Justinian, the great road maker, succeeded by this great measure of his in attracting the commerce of the eastern world of India and China and the districts outside what is now the region of Turkey, to the Bosphorus, and thereupon the commerce of Constantinople increased enormously and the city became wealthy.

Justinian is spoken of also as the bridge maker, and in the way of bridge making it would be easy to give you many striking examples of what remains. The only one I will mention now is one that I know very well at a place called Sabanja. I had read of the bridge there and wished to see it. It is a bridge which I suppose, is just about twice the length of Waterloo Bridge, and I compare it with Waterloo because, like that bridge, it has no pitch in the middle, but is entirely on a dead level. One day when it was raining very heavily and my friends were out shooting, I went exploring for this bridge. When I reached it, the first and most striking feature was that there was no water. The bridge is built over a marsh. At the end of this splendidly constructed bridge, which has lasted from about 570 down to the present time, is a *tête de pont*, under which five hundred soldiers might have sheltered themselves, who were there, of course, to guard the bridge in case of any invasion along this great road. The authorities say that in the middle of the bridge, and by the side of it, there was an inscription which ran something like the following—I did not see it because I was wet through, and I had to make certain sketches and then get back to the village about eight or ten miles away: "Thou, old river, which hast hitherto flowed by thine own will, hast been compelled for all time by the divine Justinian to flow under this bridge." As a matter of fact, the river has broken away, and there is no stream nearer than ten miles—one of Nature's practical jokes.

I have described Justinian to you as a road builder, a bridge builder, a law-giver, and a man who introduced prosperity into Constantinople. From his period to about the year 1000, with intervals, of course, there was in Constantinople a period of prosperity. We might well ask ourselves, "What was the condition of our country at that time?" Try if you can to picture what our ancestors were like in 550 and 650 and 750 A.D. We were just beginning the emigration into this country from the marshes of the Elbe and of the rivers that flow into the Black Sea. We will not say that we were highly civilised, and we will not say that we were savages at that time, but the most civilised country on the face of the earth was the country ruled from Constantinople. During

the time while our ancestors were peopling these islands and were civilising themselves, the citadel of Europe was being kept at Constantinople. There were great periods when rushes took place of masses of men, due to these periodical droughts that I have spoken of, the object of which was to get across the Bosphorus and gradually to overwhelm this part of the world as they have overwhelmed others. A period of quite exceptional drought commenced early in the sixth century and continued for upwards of a century, gradually getting worse and worse. What is the effect of drought in Arabia? The Arab shepherds attending to their flocks want pasture; if they do not get pasture they cannot live. During that time, as you all remember, Mahomet appeared as the great prophet of Arabia. One of the questions which interested me twenty-five years ago when I commenced my study of the history of Constantinople was: Where, in the name of goodness, did the enormous armies that the followers of Mahomet gathered together come from? Arabia could not furnish armies of half that number at the present time. Where did they come from? What is the explanation?

The explanation did not dawn upon me till some eight or ten years ago, when, in consequence of the explorations made in Central Asia by the United States Exploring Expedition, we who take an interest in these matters learned the fact that there were periodical droughts and times of moisture, and the time of great drought commenced in the seventh century and drove the people, the Arabs, forward to follow the followers of Mahomet wherever they could get a living. You know what wonderful progress they made. I think it is the most wonderful progress of which history bears record. They start from Mecca, they conquer the whole of Arabia and Syria and Egypt, every single country along the north shore of Africa, that is to say, on the south border of the Mediterranean, right away until you get to the Atlantic. They cross the Atlantic at the Straits of Gibraltar; they sweep over Spain and conquer every corner except that brave north-west corner which held out for 400 years against the Moslems, and then they storm over into France and, as Gibbon in his delightful, cynical manner, observed, it then looked as if succeeding generations might see a Professor of Islam at Oxford. They were met at Tours in 732 by Charles Martel, Charles the Hammer—Charles the Smasher, if you like—and he inflicted a defeat which Creasy, who, I suspect, has often stood in this room, classes among the fifteen decisive battles of the world. It was a decisive battle. It stopped the progress of Islam in that direction. But what I want you to notice for my purpose is this: that was a defeat of a wing of the great Moslem army 2,000 miles away from its centre, because whilst Islam had been making progress in the direction I have spoken of, Constantinople had resisted two tremendous sieges where all the might of Islam and all the manhood of Arabia had been brought against it. The first was the famous siege of 670 that lasted five years. At the head of it was Sophian, which means Job. Job had been the standard-bearer of Mahomet, and in a certain sense you may say that he was the St. John of Mahomet, if you may make such a comparison. He was a young fellow when Mahomet died, an old man when in 670 he led the great Moslem army to the capture of the new Rome, as it was and is called throughout the East, "New Room," as it was called by our ancestors in the time of Shakespeare: "Now is there room indeed and room enough"; and even Pope makes "Rome" rhyme with "doom." The great object of the Moslems was to capture the new Rome because Mahomet had given his blessing to everybody who should take part in the attempt and had promised paradise to all who should die in it. Well, it was a determined attempt, but it failed. Siege was laid to the city for five years, but the stout walls that are still there were bravely defended by the men within, and Christianity was saved from a Moslem invasion at that time. Then in 770 there was the biggest attempt ever made to take Constantinople, when an army of 350,000 men with a fleet of 1,800 ships came to Constantinople and determined that, if they could, they would take it that time. They besieged it for seven years, and again they failed. The ships were mostly destroyed, and the great Arab host dispersed as refugees throughout the world. The saving of Europe and European civilisation was much more marked at Constantinople than it was in the battle of Tours. But our conceited fathers and grandfathers did not give any attention to its result on European history. It is a really very great point in the history of Constantinople and of the world.

Now we have Constantinople in a flourishing condition, and, in spite of little reverses, it is steadily going ahead. But there has begun already, when we get to 1000, a movement

which is going to be the ruin of the Empire. This irregular alternation of periods of drought and of moisture was bringing into Asia Minor from South-Central Asia a stream of Nomads. We know more of the history of the Turks during the centuries between 300 and 900 than we do of the Turks of that period. The researches that have been made during the last twenty-five years have brought to light numbers of facts that were before obscure, and Sir Charles Lyall from this platform had something to do towards bringing some of the most important to light.

A stream of Turks commenced to enter the country. They were Nomads, that is to say, gipsies. They had no house, they lived in their felt tents, they lived upon their cattle, they passed from one place to another as the necessities of pasture required. They came, and they were naturally opposed by the inhabitants of the country, who were the most civilised people in Europe at that time. The little streams tended to bring great numbers together who formed themselves into groups, and became a general nuisance to the inhabitants. The first of the great mass of the Turks who entered in that way into the country were the Seljuks. I may tell you at once that the history of the Seljuks has not yet been fully made out. They were undoubtedly the most civilised of any of the groups who emigrated from South-Central Asia into what is now Asia Minor.

Those of you who have seen the wonderful ruins that they have left, will be greatly puzzled to decide where they got their art from. It is not Persian art, still less is it—as I saw it was foolishly stated the other day—Hittite art. I have seen some of the famous monuments of the Hittites, and while one is crude and barbaric, the other has a touch of refinement about it which is extremely strange. Nor is it anything like the art that some of you may have seen represented in Berlin. Some dozen years ago the Sultan Abdul Hamed made a present to the Kaiser of a great mass of slabs, one of which is certainly as long as the side of this room. These slabs, with enormous labour and at a very heavy cost, were transported to Berlin without being broken, from Mashda, on the east of the Jordan, where they were found, and I believe a special room has since been built for them. They were in a temporary room when I saw them five years ago. Their art is very remarkable. I think the best opinion is that it is an art that belongs to a period within a century of Mahomet's death, *i.e.*, it was not influenced by the teaching of Mahomet. There seems to be no representation of any teaching of his, although it is crammed full of representation.

The Seljuks undoubtedly had very great courage. They came into the country in the tenth century, and before the eleventh century they had worked their way from Konia, which is in the centre of the great plain of Asia Minor, right down to within sight of the Marmora. They had taken possession of Nicaea, the city of the Nicene Creed, and they held it in 1097 when the first and the greatest of the Crusades under Godfrey de Bouillon went from Constantinople to Nicaea. A terrible siege took place. Hideous brutalities were committed by besiegers and besieged, and it ended in the Crusaders making an arrangement with the Emperor of Constantinople to take over the city, so that he prevented the Crusaders from lingering on the pursuit of the object of their lives, which was to get to Jerusalem.

I merely mention that to show how important the Seljuks had become within 150 years of their first appearance. The ambition of the Seljuks was the ambition of every other tribe—to push on towards the north-west from the plain and to occupy New Rome. They failed. Then the Turks were attacked again and again and again, and defeated again and again and again. You have a similar story in the Old Testament about the Philistines. They come on and are defeated, and a dozen verses farther on you will find that another lot of Philistines had come over from Cyprus or somewhere else, and are again defeated. They were defeated again and again, but the stream was always running from Central Asia, and the new Nomads were coming in. Then when we get to about the end of the thirteenth century—as a matter of fact it was 1298—you have numbers of new groups of Turks working in different parts of Asia Minor, seizing blocks of land for themselves and preying upon the inhabitants. At that time a specially strong one appeared under Osman or Othman, and these are the men who are known as the Ottoman Turks. As a matter of fact Osman was declared Sultan in that year. Then you have this group gathering to itself the smaller groups that were opposed to the Seljuks, and they ultimately constituted the strongest group of Turks in Asia Minor.

Then half a century later you get to the great institution which had so much to do with the development of the Turks. Was it an inspiration on anybody's part—if I had been lecturing here a century ago, or if I had been listening to a lecture a century ago, the speaker would probably have said that it was an inspiration of the devil, but it was a clever one all the same—to take toll of the Christian children in the country and to create an army out of the Christians exclusively, that should have no connection with the Christians, breaking them off from all connection with their families and making them into an army of Islam?

The new troops were formed in this way. Some of the Sulima called the attention of the Sultan to the fact that, by sacred law, the law of Mahomet, he had a right to one-fifth of the whole of the property of all the families of races that he had conquered. In the word property was included children; and presently it became one-third of all the male children. Within twenty years from 1355, when these new troops were formed, there was a large army to whom the name was given of "new troops," or in Turkish, janissaries. The *élite* of the population, the best-looking and the most intelligent of the sons of the Christian families were taken and formed into separate regiments, and they went through a discipline of the hardest possible character. They were taught to endure hardships, taught to be skilled with their weapons; they were cut off absolutely from their families; they were forcibly converted to Mohammedanism; they were taught that all their future prospects depended upon their rank in their regiment.

The result was that there were regiments which for drill, for discipline, for courage, and for bravery had never been surpassed since the time of the Roman Pretorian Guard. These janissaries were the conquering arm of the Mohammedan hordes, and they soon made their influence felt. From this time—say from 1400—during the next fifty years, was one long period of conquest between them and the inhabitants of the country, the stream always running into Asia Minor and bringing new men to them. The Christians might fight and win as many battles as they liked, but there would always be a larger army coming in after them. With these Christian soldiers at their head the Turks were becoming invincible. You have been reading in the papers this last day or two that a great battle is expected at Kossovopol. A very great battle occurred there in which the Serbians were entirely crushed, mainly by the janissaries, and a few years afterwards you read of the great battle of Varna. We have had Varna before us also within the last three or four weeks. I went down to Varna and spent a week there, in order that I might write the account of the battle, and I know the story pretty well. I cannot tell it now; time would fail me. But at Varna, which was fought in 1444, a blunder had been made by the Turks, the Sultan, Mahomet, a boy of fifteen or sixteen only, getting into an unfortunate position. They were surrounded by their enemies under the famous John Hunyady, a skilled general, a man who had taken part in the second battle of Kossovopol. The only troops to be relied upon were the janissaries, who were under the boy Mahomet. It is the famous place of the scrap of paper. I expect you all know the story about it; if you do not I will tell you it, because we have heard of scraps of paper in this part of the world, and it is to the credit of the Turks that this scrap of paper story tells. What happened was this. A treaty of perpetual peace had been made between the young Mahomet and Ladislaus, the King of Hungary, and each had signed it and sworn to it, the Turk on the Koran, the Christian on the gospels or the crucifix. In spite of good faith this was broken by the Christians, and when the battle took place young Mahomet ordered the treaty to be stuck on the head of a lance and carried in front of the janissaries.

The story tells—it may be true, it may not, but probably it is essentially true—that he prayed: "O Christ, if Thou art God, as thy followers believe, avenge me of this perfidy!" The Christians fell on the Turks, and suffered a tremendous defeat at the hands of the janissaries—at the hands of soldiers who had been born Christians. That is the story of the Varna scrap of paper. That was in 1444, and in 1453 you have the greatest triumph that the Turks ever achieved, when they captured Constantinople. I have written the fullest account of it—I do not say the best. Now what happened was this—you can read it all very well in Gibbon, it is perhaps Gibbon's finest chapter. On that fatal May 29th two attacks had been made against the city, and John Justinius, under the brave Emperor Constantine, had resisted manfully during the two attacks, the first of which commenced at one or half-past one in the morning. At last,

when the second attack had failed, the poor fellows thought, "Now there will be a respite, and the city will not be taken this time." Then, in the language of Gibbon, which I will not attempt to improve on, because I could not, at that fatal moment up rushed the janissaries, fresh, vigorous and invincible, and carried everything before them, and before seven o'clock in the morning they had taken possession of Constantinople—New Rome. The object of the Turks had been attained. But the Turks had not finished. They went on conquering and to conquer, and they conquered every inch of the Balkans until they had conquered also Hungary, and they laid siege in 1683 to Vienna itself. But their time had come. When they laid siege to Vienna in 1683 their hour had struck. John Sobieski relieved the city, and from that time to this the story of the Turks has been one long story of decadence and of disintegration.

I cannot even attempt, as my time is running on, to point out what an enormous empire the Turkish Empire was at that time—all North Africa, part of Persia, all South Prussia, every inch of territory in the Balkans. But if you had a series of maps beginning with 1683, and reproduced a new map every thirty years afterwards right away from that time down to the present, you would find each map smaller than its predecessor. The Turk's day had passed. The zenith was in 1683. I ask you to tell me where it is in 1915. I will not attempt to speak of it.

Now I must say something of the Turkish rule in Asia. The great fault of the Turk is that he has never succeeded in governing subject races. Lord Cromer declared that I had put my finger on the spot when I made that statement in a book that I had recently published. Turkey has never succeeded in ruling subject races. She could never be just to them; and if you want a ghastly story of it I must simply allude to the story of the Armenians, because I should keep you for another hour at least if I dealt with it in detail. The Armenians, all things considered, are the manliest race in Asia Minor. They are fine fellows physically. They come from that great central plain of Asia Minor. It begins in the Konia district at an elevation of 2,500 feet, and it rises steadily till you reach some 6,200 feet. You have it at Batoum, which is quite in the other direction, towards Alexandretta, which has always preserved a certain amount of independence. Abdul Hamed wanted some twenty years ago to exterminate every Armenian in Batoum, and a number of Ministers and others—I count myself happy to have been one of them—brought all the influence we could to bear upon every Ambassador in Constantinople, and we got a message to the Sultan to say that it would not be permitted. So the Armenians in Batoum were saved.

The Armenians are a strikingly interesting people. The point about them which I think would interest you most is the differences between them and the rest of the Christian population of Asia Minor. They have always been singularly independent. They accepted Christianity as the religion of the State before the Orthodox Church did. Their great saint, Saint Gregory the Illuminator, must have been a singularly remarkable man. Probably some of you do not know that the Armenians celebrate their Christmas Day, not on December 25th, but usually about January 15th. The explanation of that is a very curious and interesting one, which shows the character of the Armenian people. The Armenians have always been strong monotheists. You will recall that the three great monotheistic religions of the world, Judaism, Christianity and Islam, all come from that part of the world, from Syria or Arabia. At the time when Christianity was introduced and was beginning to spread, say in the first, second, and third centuries, the most popular form of Paganism in Asia Minor and all throughout South Arabia was Mithraism. If you go to the York Museum you will find traces of Mithraism there. Some of the soldiers in the Anatolian regiments were apparently Mithraists, and you can find the emblems on the tombstones that have been preserved. This Mithraism was a curious sort of creed. Tertullian, whose authority no one will dispute, writing in the second century, said: "Mithraism is a travesty of Christianity invented by the devil centuries before Christ was born in order to deceive the elect." The great feature of the independence of the Armenians that I want to call attention to is this: the birthday of Mithra was celebrated on December 25th. It is known to have been celebrated on that date three centuries before Christ. When the Western Church and the Orthodox Church also—not the Armenian Church—arranged their festivals, they said: "We will have nothing to do with that. This is a great feast. It is recognised by the whole of the followers of Mithra, and as

we cannot tolerate a Mithraic feast we must convert it into a Christian feast." The attitude of the Armenians, on the other hand, was: "We will not have anything to do with Mithraism. We will not celebrate the birth of Christ at the same time as the birthday of Mithra has been celebrated," and so they decided that Christmas Day should be celebrated at a different time. The decree has gone forth apparently that the Armenians are to be exterminated. Similar decrees have gone forward before this, but they are not yet exterminated.

Passing from them and returning to Constantinople, there is only one further matter to which I wish to direct your attention. I have spoken of the great roads which Justinian made by which he diverted the traffic from the Persian Gulf to the Bosphorus. Can Constantinople ever again become the great commercial city which it was, and continued to be, until the conquest by the Turks in 1453? In my opinion it is quite impossible, for various reasons. It attained that eminence centuries ago for the reasons that I have endeavoured to explain. The tendency of events, I will not say of physical causes, has been to diminish its importance as a commercial city. Steam has struck it a heavy blow. The opening of the Suez Canal has struck it a still heavier one. Steam rendered Constantinople as a commercial city this disservice. Up to that time Constantinople was a centre for the collection and distribution of merchandise. Small sailing vessels came from the islands and from all parts round the Marmora and Black Sea, the centre being Constantinople. Their goods were transferred into big ships, and they were taken to Western ports or even to Russia. That has passed away. Under steam the big steamer goes round and collects her goods, and this small traffic has disappeared. But a still greater hindrance to Constantinople recovering its ancient reputation is the opening of the Suez Canal. It is true that water carriage is always enormously cheaper than land carriage. The cost of transporting merchandise consists in what the French call *manutention* in the handling of the goods. If you are going to attempt to bring goods from India or from China to the Persian Gulf, then to discharge the ship and put the goods on board a train on the Baghdad Railway, for example, take them to Constantinople, and then take them out and put them on board another ship, you are engaging in a very costly process. The Turks have built very large hopes on the success of the Baghdad Railway. I have never opposed it. The Baghdad Railway will be an excellent thing for the country, but to suppose that it is going to draw towards it the traffic from India and from the East is to ignore facts. You cannot get over the difficulty that the handling of goods will always enormously increase the cost of transport. If the goods are heavy goods — and that is the case with most of them, such as rice, grain, coffee, and so on —the fact, if they are carried by water, that the voyage will take a few days longer, is a matter of very little account. If you are thinking of passengers, those who know the country—and the Chairman is one—will tell you at once that they are not particularly ambitious of making a journey across the hot plains of Mesopotamia in the summer weather, if they can get a P. & O. boat round by the Red Sea and the Canal. So I say that even supposing the Baghdad Railway will be completed, as it will be completed—it is nearly completed now—while the advantage to Asiatic Turkey will be great, there is nothing to be feared from the competition of Eastern trade; and anybody who thinks that the great bulk of the Eastern trade will be attracted through Turkey in that kind of way is a dreamer who ignores facts.

I have already detained you much longer than I had hoped to do. I have left unsaid many things which I should like to have said, but I hope I have given you an idea of the general condition of Turkey, so that you can add it to the store of ideas that you already possess.

DISCUSSION.

THE CHAIRMAN (Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc.), in opening the discussion, said he wished to draw attention to one or two points upon which somewhat different views had recently been expressed from those given by the author. For instance, the rise and fall of the famous city of Palmyra had recently been very ably discussed in an excellent book by Sir Mark Sykes called "The Heritage of the Kaliphs," and he did not give the fact of the desiccation of the country south of Palmyra by any means as the chief reason for the decay of that city. He made some very caustic remarks on the subject of the greatness of Palmyra in her best days, and drew a somewhat unkind parallel between the best of the Palmyra ruins and the Hotel Cecil. The audience would have been able to appreciate very much more what Sir Edwin had said in regard to the position of the Justinian roads if a map had been exhibited on which the author could have pointed out exactly where they ran. With regard

to the rise of Mahomet, he did not think there was any necessity to appeal to any country further than Western Arabia for the mass of the men who followed him to victory right through Central Asia. At the beginning of things he certainly thought the whole of his army was purely Arabian. There was no doubt that when he got into Central Asia he began, as conquerors always did, to rope in the various tribes whom he had subjected, so that his army was swollen with a very large force of people who were not Arabian. But at the commencement he had no doubt that the backbone of Mahomet's army was Arabian. He would be very glad to have the author's opinion on the real cause of the decay of the Ottoman Empire. Sir Edwin had mentioned that the Ottomans pressed into their service the janissaries who were recruited and derived from Christian sources. There was no doubt that the strength of the army in the early days of the Ottoman Empire was derived from those so-called Christian forces. He believed that the Christians were not only brought up and educated as fighting men, but as administrators, and that for some two or three centuries at least the Ottoman Empire was largely administered by men who originally were Christians, in fact by men of the same stamp as those who were enlisted as janissaries. He knew of one authority who distinctly traced the decadence of the Ottoman Empire to a change of the administration which discarded the Christians and put the chief administrative powers into the hands of the Turks.

Mr. G. Hagopian said he had been told, and believed, that the early Emperors of the Turks were men of character and of justice, and it was justice that drew to their flag so many of the peoples of the races of the Near East. But a time arrived when justice gave place to tyranny, and the author had given particulars of how that tyranny had worked. It was impossible for a nation to prosper which massacred its subjects and its bread-winners, and those to whom it was beholden for its very existence. It was impossible to have in one nation two sorts of intelligence, two systems of justice, civilisation and progress the one contrary to the other, and it was due to pursuing that course that Turkey had come to its present position. He desired to ask the author, who had lived for forty years in Constantinople, and had been a practitioner before the Turkish courts as well as before the British Consular court, how many Turkish administrators had ever told him anything worth a penny about political economy, the wealth of nations, and all that made a country rich and prosperous. One could not understand the Armenian people unless their literature was compared with that of other communities. Certain parts of it bore the stamp of the greatest antiquity, and the language was one of the most powerful in the world. A nation which used such inspiring, eloquent and majestic language could never be suppressed. Personally, he was the master of several languages, so that he spoke from knowledge when he expressed that opinion — an opinion shared by one of the generals of the German army, who said to a Turkish officer at Versailles in 1870 that the Armenian language was the most expressive of the fourteen languages he knew, and that the declaration by the Emperor William to the princes and people of Germany in regard to the formation of the Empire should have been made in Armenian, as it was the only language suitable for such an occasion.

Mr. H. Charles Woods thought the misrule in Turkey was entirely due to the fact, as the author had stated, that the Turks could not rule, and never had understood how to rule. It was also due, at least in modern times, to the lack of road and railway construction. Had the Young Turks done something to prove the *bonâ fide* character of the Government to the people their position might have been quite different from what it was at the present time, and one of the best ways of doing that would have been to have carried out something in the way of public works. With reference to the question of the Armenian massacres, it was a most important point to bear in mind that when the massacres had taken place they were first of all by the order of the Central Government and then by the order of the local authorities. When the general order went out from Constantinople, it was carried out by the local authorities. The Turk might love to kill a Christian, but he did not massacre Armenians on a large scale without an order. That was an extremely important point at the present time, because it was an absolute proof that the dreadful massacres which had recently taken place could have been stopped by the Turks and by the Germans. Any little knowledge he personally possessed of the Near East and its peoples was largely the result of the tuition he had received from the author, to whom he was extremely grateful for his past and present help.

Sir Edwin Pears, in reply, said he entirely agreed with what Mr. Woods had said in reference to the Armenian massacres being by order. All the massacres between 1892 and 1898 were executed on the orders of Abdul Hamed. It was most important for the people of this country not to imagine that the massacres were due to an outbreak on the part of the Moslem population. It was nothing of the sort; it was due to the damnable character of Abdul Hamed. Abdul Hamed might at any time have stopped the massacres if he cared to do so. Lord Cromer had made practically the same remark, and he entirely agreed with him. Sir Mark Sykes in the book he had written mentioned how a Turk that he came across was heartily ashamed of the loathsome murders that were committed upon the Christians. It was most important that those murders

should not be put down to the Islam population, because in India there were great masses of perfectly loyal Islamic troops who did not back up the barbarism of Abdul Hamed and his satellites. He entirely sympathised with the remark made by Professor Morgan at a meeting held on the previous evening that English people often did not take sufficient credit to themselves for their virtues, and that the people in this country had the purest administration in Europe. The English race had the reputation throughout the whole of the East of being the one race that loved justice, a reputation they had held since the year 1100, when their ancestors and cousins went out there and were admired because of their love of justice. British people executed justice throughout the East, and for that reason were believed to be a justice-loving people. That was the finest character that could be given to a nation.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Sir Edwin Pears for his interesting and instructive paper, and the meeting terminated.

HOME INDUSTRIES IN THE HIGHLANDS AND ISLANDS OF SCOTLAND.

The problem of developing crafts and industries in the Scottish highlands and islands is one which at long intervals attracts the attention of the Government, and leads to an inquiry and the initiation of some new scheme, or the modification of some old scheme, for providing the crofters and their families with remunerative occupations which will enable them to supplement the bare living which they can extract from agriculture. The most recent inquiry was undertaken by Dr. W. R. Scott at the request of the Board of Agriculture for Scotland. His report deals with three main industries—tweed-making in Harris and the Hebrides generally, hosiery-knitting in Shetland, and kelp-making in Orkney, and, to a less extent, in the Hebrides. The information which follows is taken from the September number of the *Monthly Bulletin of Economic and Social Intelligence*, in which Dr. Scott's report is examined at some length. "Harris" tweed, or a tweed of the same type, is manufactured in the homes of the crofters in the islands of Harris, Lewis, North Uist, South Uist, and, to a small extent, on the mainland in the Western Highlands. In all the processes, except the actual weaving of the yarn, the majority of the workers are women, and in the production of the best cloth the only part of the work entrusted to machinery is the carding; all the other processes—washing, dyeing, spinning, weaving, and finishing—being carried out by hand. Spinning occupies the greater part of the time required for making the cloth, and the temptation to substitute machine-spun yarn for yarn spun by hand is for that reason very great, and such substitution is one of the chief difficulties which is encountered in any attempt to organise the industry. The workers who make the cloth dispose of it to local merchants, or sell it through a voluntary association for the encouragement of the industry, such as the Scottish Home Industries Association or the Crofters' Agency.

The average price paid in 1911 to the makers of the tweed was 3*s.* per yard, and the cloth sold retail at 4*s.* 6*d.* per yard. The nominal earnings of the women workers in the same year were about 10*s.* a week—a sum which represents a very substantial addition to the family income.

Hosiery-knitting in the Shetlands had a curious origin. The art was taught to the islanders by Spanish sailors, the survivors of a galleon belonging to the Armada, wrecked on Fair Island in 1588. The organisation of the industry is of the simplest type. The women knit in their spare time and accomplish most of the work in winter, though they knit industriously in summer in the open air whenever they have no other work which claims their attention. In some cases the wool is hand-carded and hand-spun, but in many cases one or both of these processes is performed by machinery. Shetland wool is of exquisite fineness, and machine-carding is considered by some of the workers to ruin the fine fibres. Shetland hosiery is always made in the natural colours of the wool; but Fair Island hosiery is dyed in bright colours, which, unfortunately, are not always harmonious. It is estimated that the women earn at the work from 4*s.* to 6*s.* a week, and though these earnings seem small it must be remembered that the women, when knitting and spinning, are really employing time which would otherwise remain unutilised, and that, as they can knit and chat with their friends and set their own pace in working, the fatigue is probably not great, and there is often even a balance of enjoyment in the work.

Kelp-making is not strictly speaking a home industry, but it is an industry in the same position inasmuch as it is supplementary to agriculture, and this is sufficient to justify its inclusion in Dr. Scott's report. Kelp is obtained by burning seaweed in the open air in specially-constructed kilns, or in shallow holes dug in the earth. The residue from the burning, while hot, is stirred into a glutinous mass which hardens on cooling into a greyish substance resembling coarse lava. In this form it is exported, being valuable chiefly for the iodine and potash salts which it contains. The industry was introduced into the Orkneys in 1722, and soon spread to North Uist and other islands in the Hebrides. The price obtained for the product has fluctuated in a remarkable manner. In the first years the price at times fell below £1 a ton, while during the war with France the price was as high as £20 a ton; and from 1800 to 1820 the average price was £10 10*s.* a ton. From 1840 to 1870 the industry was depressed; but since then it has recovered, and its prospects at the present time are distinctly good.

The Board of Agriculture for Scotland has wide powers in connection with the encouragement of domestic industries in the highlands and islands. Already it is doing much for the promotion of agriculture, and particularly for the encouragement of sheep-breeding, and this work indirectly assists the home industries by furnishing the workers with improved raw material; but Dr. Scott points out that this is not sufficient to secure the development of such industries. A broad scheme of technical instruction is necessary, and, by making the fullest possible use of the many voluntary committees and associations which exist and which are doing good work in promoting home industries, the cost of a scheme of instruction would not be unduly heavy. A number of minor home industries are carried on in various places in the highlands and islands. Lace-making is of some importance at Tarbert and New Pitsligo; basket-making is carried on at Portree and Kilmuir; and there is a small rug-making industry in Shetland. There are others—straw-plaiting, pottery and metal work—which are at present upon a very small scale indeed, but which might quite possibly be developed into industries of some size.

CORRESPONDENCE.

PAINTING AND PREVENTION OF RUST.

With regard to the article on the above subject in the *Journal* of November 19th, I am of the opinion that most manufacturers, etc., paint iron firstly with a coat of either red or grey lead paint, and then put the required coloured paint on in any number of coats desired. The lead paint evidently prevents the rust referred to.

D. R. BROADBENT.

NOTES ON BOOKS.

OLD LONDON'S SPAS, BATHS, AND WELLS. By Septimus Sunderland, M.D. London: J. Bale, Sons & Danielsson, Ltd. 7*s.* 6*d.* net.

Dr. Sunderland is an expert in Balneology, and this book is founded on his Address as President of the Balneological and Climatological Section of the Royal Society of Medicine. It is dedicated to the memory of Sir Edward Sieveking, the first Honorary President; Dr. Henry Lewis, of Folkestone, first President; and Dr. Samuel Hyde, of Buxton, first Chairman of Council of the British Balneological and Climatological Society, now incorporated with the Royal Society of Medicine. The main object of the society is to help towards the recognition of the value of the baths and waters of Great Britain, one of the most important questions of the day when invalids are confined to those of our own country. A committee of the section, in reply to the expressed wish of the military authorities, have prepared a pamphlet for the War Office, specifying "the various morbid conditions of our wounded and invalid sailors and soldiers requiring special treatment," together with a list of British health resorts indicated for their relief; with the gratifying result that many of the British spas have made special arrangements for the reception of military patients whose recovery would be hastened by the use of waters and baths.

This volume contains a valuable collection of notes on Old London spas, baths, and wells; but the classification is a little confused, and the distinction between the wells of pure water used for domestic purposes and the medicinal waters is not well defined. Moreover, some spas outside London are included. The list of the wells of Old London is, of course, only of archæological interest, as few of them are of any value now. It is, however, of considerable topographical interest.

Fitzstephen's remarkable description of London in the twelfth century contains a very alluring account of its abundant water supply: "The wells send up fountains of sweet and wholesome water, which glistens as it runs over the pebbles, the flowing streams and the pleasant clack of the watermills make music on all sides." We find this pleasant picture vouched for by the fact that gardens, the best in Old London, followed the course of the Walbrook for some centuries after the Roman domination. Stow says that "in every street and lane of the city are divers fair wells and fresh springs; and after this manner was the city then served, with sweet and fresh waters, which being since decayed, other means have been sought to supply the want."

When the wells ceased to give the inhabitants of London a sufficient water supply, the people were forced to depend upon the conduits and the tankard-bearers who brought the water to their houses. The tankards were wooden vessels, broad at the bottom but very narrow at the top. They were bound with iron hoops, and held about three gallons. Old maps show groups of these at various stations. In Agas's map of London the water-carriers are represented as drawing from the Thames at the Tower Stairs. These men were commonly called Cobs; so Ben Jonson named one of the characters in "Every Man in his Humour" Oliver Cob, a water-carrier, who lived "at the sign of the 'Water Tankard,' hard by the 'Green Lattice.'" Thames water continued pure for some centuries, in spite of the surface drainage into it.

The subject of this book may be divided under the following heads: (1) Holy Wells; (2) Spas and other Medicinal Wells; (3) Baths and Hot Baths.

(1) Holy Wells were mostly connected with certain religious houses. Two of the holy wells have given names to well-known streets. The one connected with Haliwell Priory, Shoreditch, was known before the foundation of this nunnery in the twelfth century, and Holywell Street, Strand, now passed away, was of considerable antiquity. Holy wells were seldom medicinal, although they may have been reputed to possess miraculous properties. The name of St. Chad (Ceadda), the patron saint of medicinal springs and wells, is

naturally associated with many springs. He was Bishop of Mercia, and settled his see at Lichfield, outside which place his well remains at Stow. His devotees who visited his shrine found his dust mingled with a little water to have a marvellous virtue in the cure of divers diseases.

St. Chad's Well in London was near Battle Bridge, not far from the site of the present King's Cross. St. Chad's Place keeps it in memory. It was supposed to have medicinal virtues, and pleasure gardens were attached to it; but it soon declined in public favour. Another St. Chad's well was situated at Shadwell, near Wapping. Lysons suggested that Shad was a variety of Chad. A Dr. Linden wrote a pamphlet to prove it could cure every disease. Others limited its virtues to the efficacy of the water in cutaneous diseases; but we cannot trust the doctors of the seventeenth and eighteenth centuries. The chapel of Our Lady of Muswell was famous as a place of pilgrimage, and the wells were believed to have miraculous virtues, but there is no evidence that they had any medicinal value. Another Lady well was at Brockley, and was said to be a holy well. Clerkenwell and Skinner's Well had great fame.

(2) Spas and other Medicinal Wells. When certain wells obtained fame by vigorous advertising, the proprietors found it worth their while to add the attraction of assembly rooms, so as to draw pleasure-seekers to their gardens; but although pump-rooms were added, there is little to make us believe that many of the visitors were troubled to drink the waters. The author, however, holds the opinion that in many instances the London spas were useful and valuable, and could be regarded as health resorts for country people as well as Londoners, "at a period when the undertaking of journeys was full of difficulty." Certainly in the eighteenth century South Lambeth was considered to be a health resort, and connections of the reviewer during the Napoleonic wars spent their holidays and drank the waters at Blackheath.

Some of the Old London spas had considerable repute, and the Hampstead Spa was one of the most popular. In 1698 the medicinal spring and six acres of land, known as the Wells Charity Estate, were presented to the poor of Hampstead by the Countess of Gainsborough and her son, and in 1700 an attempt was made to sell the water in flasks. New buildings in Well Walk were erected about 1701, containing an assembly room, a long room, and a pump-room. Dr. Gibbons asserted that the waters were "not inferior to any of our chalybeate springs, and coming very near Pyrmont in quality." The proprietor became bankrupt, and in 1725 the buildings were turned into a chapel. Two years afterwards an attempt was made to revive the spa, but with little success, although Dr. John Soame styled it "the inexhaustible fountain of health."

Marylebone Spa, opened in 1774 in Marylebone Gardens, had much success; but Dr. Sunderland is forced to condemn it as having been one of the spurious spas. Pancras Wells, Bagnigge Wells, New Tunbridge Wells, Islington, Sadlers Wells, Bermondsey Spa, and St. George's Spa were popular, but the frequenters of the gardens were often of a riff-raff character. Among the medicinal springs Cripplegate Well, Canonbury Springs, and Ladywell Springs had a certain repute. Mostly were chalybeate, some aperient. Beulah Spa was one of the latest. It was discovered in 1828, and continued until 1855. Magnesium sulphate is a common constituent of the waters of the Old London spas, and those containing sodium sulphate are frequently praised.

(3) Baths and Hot Baths form an interesting chapter in the history of London waters; but this is too large a subject to be treated here. The waters of St. Agnes le Clair Well, near Old Street, were deemed useful for skin and eye troubles.

Hummums and Bagnios were very popular for a time, but they died in disgrace, to be revived in our own days as Turkish baths. The old Roman Spring Bath at No. 5, Strand is one of the most interesting relics of Old London.

The vicissitudes of the early London water supply may be shortly indicated in the statement of a few dates. Stow tells us that water was first brought in pipes from Tyburn in 1236, and the great conduit in West Cheap was begun in 1285. Peter Morris pumped up Thames water by waterwheels in 1581. The New River was brought to London from the wells at Chadwell and Amwell, in Hertfordshire, and completed in 1613. In 1691 the York Buildings Waterworks Company was formed. The Chelsea Waterworks were established in 1723, and the Lambeth Waterworks in 1785. The Vauxhall Waterworks followed in 1805, the West Middlesex in 1806, and the Grand Junction in 1811.

Public pumps supplied by old wells were condemned after the severe visitation of cholera in 1866, and in 1875 there were only four in use—those at Aldgate, Bartholomew Lane, Crutched Friars, and Fann Street. They were soon after closed as dangerous to public health.

In conclusion, note may be made of the concluding chapter on "Modern Spa Treatment in Great Britain," in which the author enumerates the chief of these, and adds: "We possess mineral waters which are as useful as those of the Continental spas. In many of the above-mentioned places treatment can be carried out quite as efficaciously and satisfactorily as at foreign stations." One could wish that this chapter had been longer and fuller of information, for the utilisation of our medicinal waters as here indicated is a matter of immense national importance. Much has been done of late years. This volume contains many illustrations of interest. H. B. W.

Painting by Immersion and by Compressed Air. By Arthur Seymour Jennings, F.I.B.D. London: "The Managing Engineer," and E. & F. N. Spon, Ltd. 10*s*. 6*d*. net.

The substitution of immersion or the compressed-air process for the brush in the application of paint

has made great progress in the United States of America and in many parts of the continent. It is by no means unknown in this country. At Woolwich Arsenal, for instance, the plant for painting waggons, etc., has been in use for a dozen years, and has proved very successful, forty men being able to turn out as much work as the two hundred painters who were formerly employed there. But it seems clear that there is room for a very great extension of the process in Great Britain, for, under suitable conditions, it can effect immense saving both of time and labour. The author gives a list of some two hundred and fifty of the principal articles to which the process can be applied. These vary in size and nature from hooks and eyes to pianos and organs, and when it is added that a complete coat of enamel can be given to the body of a four-seated touring-car in two minutes, it will be seen that Mr. Jennings's handbook contains matter worthy the attention of all sorts and conditions of manufacturers.

With regard to the question whether paint applied by these methods is as durable as that applied by the brush, Mr. Jennings answers that when properly prepared it gives even better results, and has this additional advantage, that the paint finds its way into places which a brush could not reach, such as the open joints of a waggon, the intricate parts of certain agricultural machinery, and so forth.

The book is eminently practical. It describes the various kinds of tanks used, the hoists, trolleys, etc., the requirements of different trades, and the paints suitable for different kinds of work. There are also 150 illustrations, showing apparatus, methods of procedure, etc., and an excellent index.

GENERAL NOTES.

Memorial Tablets. — The London County Council have affixed a bronze tablet on No. 23, Highbury Place, the residence for some twenty years of the Chamberlain family. Joseph Chamberlain *senior* moved to this house in 1845, at which time the son was nine years of age. The Right Hon. Joseph Chamberlain was connected with two other houses in London—No. 188, Camberwell Grove, where he was born, and No. 40, Prince's Gardens, where he died—and it has been decided to erect tablets on each of these houses as well. A bronze tablet has also been affixed on No. 12, Park Crescent, where Lord Lister resided from 1877, when he first came to London as Professor of Clinical Surgery at King's College Hospital, till his death in 1912.

Ducks and Mosquitoes.—Ducks are among the greatest enemies of mosquitoes, and consequently of yellow fever and malaria. The *Colonial Journal* mentions an experiment carried out to prove their value in this particular. Two pools of equal area were made in a stream. Ducks were placed in one and fish in the other. The first was speedily cleared of mosquitoes, while the second continued to maintain the insects in all stages of development. Wild ducks were then introduced, and found to prefer the insects to all other foods. At the end of twenty-four hours no pupae were found in the pond, and after two days all the larvae had been destroyed. These experiments confirm the observations of William Lockwood, who found that the duck was particularly adapted to devouring the larvae on the surface of water, and of McAtee, who found mosquitoes in the gizzard of a wild duck.

The Trade of Khorasan of 1915.—The report on the trade of the large and important Persian province of Khorasan states that there is far greater opening for British trade than might have been inferred from recent reports. Russian goods reach Meshed, the capital of the province and most sacred city of Persia, by waggon in the course of a few days, while British and Indian goods, conveyed by pack animals by the Nushki trade route, take a period of never less than three and sometimes more than nine months. Were communications improved, thread, tissues, tobacco, cigarettes, wearing apparel, sugar, indigo, tanned and untanned hides, manufactured leather, drugs, carpets, mercury, hardware, and other goods from the United Kingdom and India might replace to a great extent the imports from other countries, and practically the whole of the carrying trade in Indian tea, much of which is at present carried by sea from India, would be secured for the Nushki route. One step towards the improvement of communications would be the establishment of a trustworthy and efficient forwarding agency between Meshed and Nushki. Again, the substitution of wheeled for pack transport along the greater part, if not the whole of the route, would remove another obstacle in the way of the expansion of British trade, and should be practicable with slight improvements to the road in places. What is most urgently required, however, is the extension of the railway to, or at least towards, the frontier. Nushki is twenty stages distant from the frontier, and the elimination of this tedious and arid route would greatly encourage trade.

Coir Mats in the Philippines.—The Industrial Division of the Bureau of Education at Manila has announced that commercial quantities of coir or coconut-husk mats of Philippine manufacture are now available for sale in the Philippines, and in the East generally, at prices which allow successful competition with American and European mats of this material. Raw material for the mats is to be had in abundance in the islands, of course, but the training of workmen for the manufacture of the mats has required time, and any wide development of the trade will require more time for that reason. The imports of such goods into China are considerable.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.

DECEMBER 1. — THE MASTER OF CHRIST'S COLLEGE, CAMBRIDGE (Arthur Everett Shipley, Sc.D., F.R.S.), "Insects and War." SIR WILLIAM J. COLLINS, K.C.V.O., M.S., F.R.C.S., will preside.

DECEMBER 8.—LIEUT.-COLONEL W. A. TILNEY, F.R.G.S., F.R.A.S., late 17th Lancers, "The Art of Finding your Way at Night without a Compass." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, will preside.

DECEMBER 15.—J. JEF. DENYN, Carillonneur de Malines, and WILLIAM W. STARMER, F.R.A.M., "Carillons and Carillon Playing." (With illustrations.)

COLONIAL SECTION.

Tuesday afternoon, at 4.30 p.m. :—

NOVEMBER 30. — SIR SYDNEY OLIVIER, K.C.M.G., late Governor of Jamaica, "Recent Developments in Jamaica: Internal and External." SIR HENRY A. BLAKE, G.C.M.G., will preside.

INDIAN SECTION.

Thursday afternoon, at 4.30 p.m. :—

DECEMBER 16.—C. C. MCLEOD, President of the London Jute Association, "The Indian Jute Industry." SIR JOHN PRESCOTT HEWETT, G.C.S.I., C.I.E., will preside.

Papers to be read after Christmas :—

PROFESSOR J. A. FLEMING, M.A., D.Sc., F.R.S., "The Organisation of Scientific Research." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, will preside.

R. W. SETON-WATSON, D.Litt., "The Balkan Problem."

CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Optical Appliances in Warfare."

LAWRENCE CHUBB, "The Common Lands of London: the Story of their Preservation."

REV. P. H. DITCHFIELD, "The England of Shakespeare."

W. A. CRAIGIE, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

VICTOR HORTA, Directeur de l'Académie Royale des Beaux-Arts de la Ville de Bruxelles, "Belgian Architecture."

CHARLES DELCHEVALERIE, "Belgian Literature."

LESLIE URQUHART, "The Economic Development of Russia."

J. ARTHUR HUTTON, Chairman of the British Cotton Growing Association, "The Effect of the War on Cotton Growing in the British Empire."

S. CHARLES PHILLIPS, M.S.C.I., "Paper Supplies as affected by the War."

PROFESSOR T. G. MASARYK, "The Slavonic Peoples."

COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., late Survey of India, "The Romance of the Indian Ordnance Survey."

C. A. KINCAID, C.V.O., Indian Civil Service, "The Saints of Pandharpur."

SIR DANIEL MORRIS, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland."

PROFESSOR WYNDHAM R. DUNSTAN, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India."

INDIAN SECTION.

Thursday afternoons at 4.30 p.m. :—

January 13, February 17, March 16, April 6, May 18.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m. :—

February 1, March 7, May 2.

CANTOR LECTURES.

Monday afternoons at 4.30 p.m. :—

WALTER ROSENHAIN, D.Sc., F.R.S., Superintendent, Metallurgy Department, National Physical Laboratory, "Optical Glass." Three Lectures.

Syllabus.

LECTURE I.—NOVEMBER 29.—Comparison of optical with ordinary glass—Defects and properties of glass for optical purposes — Transparency—Colour—Bubbles and defects — Striæ or veins—Internal strain and annealing — Hardness and durability—Testing of optical glass—The optical properties of glass—Refraction and dispersion—Their relation in crown and flint glasses—Glasses introduced by Schott and Abbe—Partial dispersions and the secondary spectrum—Apochromatic glasses and lenses.

LECTURE II.—DECEMBER 6.—History of optical glass manufacture — Fraunhofer, Guinand, Feil, Bontemps, Chance—Schott and Abbe—Hopkinson and Stokes—Efforts in England. The present method of optical glass manufacture—The furnace —The pot—Production and treatment—The process of melting and fining—Stirring and finishing —Cooling—Breaking up, selecting and moulding —Annealing—The final form of the glass.

LECTURE III.—DECEMBER 13.—The present process of manufacture—General difficulties—Costliness—Cost of the pot—Time of production—Cost of melting—Raw materials—Low yield of good glass—Risks of the process—Risks of loss during melting—Failures due to striæ—Risks of contamination—Errors and variations of optical constants—Range of glasses demanded by opticians—Small quantities required—Need for large stock of optical glass. Special difficulties in England—Cost of raw materials and of labour—Refractories. Special difficulties connected with "new" glasses—Their chemical activity—Action on pots—Absorption of colouring impurities—Attainment of extreme optical properties. Need for research—The general problem—How to make good optical glass—Necessary improvements in pots and refractories, and in furnaces and methods of working—Utilisation of new materials and electric methods—The special problems relating to individual types of glasses—Optical and other properties to be realised simultaneously—The limitations of possible glasses—Optical properties of crystalline media—Future possibilities.

J. ERSKINE-MURRAY, D.Sc., F.R.S.E., M.I.E.E., "Vibrations, Waves, and Resonance." Four Lectures.

May 1, 8, 15, 22.

FOTHERGILL LECTURES.

Monday afternoons, at 4.30 p.m.:—

REV. DR. HERBERT WEST, D.D., A.R.I.B.A. (author of "Gothic Architecture in England and France"), "Flemish Architecture." Three Lectures.

February 7, 14, 21.

EDWARD A. REEVES, F.R.A.S., Map Curator, Royal Geographical Society, "Surveying." Three Lectures.

March 27, April 3, 10.

JUVENILE LECTURES.

These Lectures will be given on Wednesday afternoons, January 5 and 12, at 3 p.m. The first lecture will be given by Professor John Millar Thomson, LL.D., F.R.S., on "Crystallisation," and the second by Mr. James Swinburne, F.R.S., on "Science of some Toys."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, NOVEMBER 29...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cantor Lecture.) Mr. W. Rosenhain, "Optical Glass."

Geographical Society, Burlington-gardens, W., 8.30 p.m. Sir Charles Metcalfe, "The Railway Development of Africa, Present and Future."

Actuaries, Institute of, Staple Inn Hall, Holborn, W.C., 5 p.m.

TUESDAY, NOVEMBER 30...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Sir Sydney Olivier, "Recent Developments in Jamaica: Internal and External."

Sociological Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8.15 p.m. Mr. A. E. Zimmern, "Nationality and Government."

Roman Studies, Society for the Promotion of, at the Royal Society, Burlington House, W., 4.30 p.m. Mr. G. McN. Rushforth, "Funeral Lights in Roman Sepulchral Monuments."

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. 1. Mr. D. E. Lloyd-Davies, "Harbour and Coast-Defence Works at Alexandria." 2. Mr. C. A. Trery, "Galvan Port, Bahia Blanca, Argentine."

Photographic Society, 35, Russell-square, W.C., 8 p.m. Mr. H. W. Fincham, "Ely Cathedral."

WEDNESDAY, DECEMBER 1...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. The Master of Christ's College, Cambridge (Arthur Everett Shipley), "Insects and War."

Geological Society, Burlington House, W., 8 p.m.

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m. 1. Dr. G. D. Lander, "The Microchemistry of some Alkaloids." 2. Mr. W. Partridge, "The 'Presumptive Coli Test' on Unchilled Water." 3. Mr. E. R. Bolton, "Notes on Methods of Analysing Oleaginous Seeds and Fruits."

Entomological Society, 11, Chandos-street, W., 8 p.m.

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. J. C. Hannah, "Irish Cathedrals."

Sanitary Engineers, Institute of, Caxton Hall, Westminster, S.W., 8 p.m. Dr. W. E. Adeney, "The Disposal of Sewage by Dilution: a Bio-Chemical Method."

THURSDAY, DECEMBER 2...Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Chemical Society, Burlington House, W., 8 p.m. 1. Mr. P. Blackman, "A comparative method for determining vapour densities." (Continued.) 2. Messrs. O. L. Brady and F. P. Dunn, "The Isomerism of the oximes. Part VII.—5-Bromvanillinaldoxime, 5-nitrovanillinaldoxime and 6-nitropiperonaldoxime. 3. Mr. A. Slator, "The rate of growth of bacteria." 4. Mr. A. Bramley, "The study of binary mixtures. Part I.—The densities and viscosities of mixtures containing phenol." 5. Messrs. R. H. Callow, W. C. McC. Lewis, and G. Nodder, "Studies in catalysis. Part III.—Preliminary measurements of the infra-red absorption spectra of hydrogen chloride, potassium chloride, and methyl acetate in aqueous solution." 6. Mr. R. O. Griffith, "Studies in catalysis. Part IV.—Stoichiometric and catalytic effects due to the progressive displacement of one reactant by another in the 'acid' hydrolysis of methyl acetate." 7. Mr. A. K. Macbeth, "Colorations produced by some organic nitrocompounds with special reference to tetranitromethane." (Part II.) 8. Mr. S. G. Sastry, "The catalytic bleaching of palm-oil." 9. Messrs. W. A. Haward and T. Otagawa, "The propagation of flame in mixtures of hydrogen and air. The 'uniform movement.'"

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. A. H. Blake, "Samuel Pepys and his Times."

FRIDAY, DECEMBER 3...Geologists' Association, University College, W.C., 8 p.m.

／
Journal of the Royal Society of Arts.

No. 3,289. VOL. LXIV.

FRIDAY, DECEMBER 3, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 6th, at 4.30 p.m. (Cantor Lecture.) WALTER ROSENHAIN, D.Sc., F.R.S., Superintendent, Metallurgy Department, National Physical Laboratory, "Optical Glass." (Lecture II.)

WEDNESDAY, DECEMBER 8th, at 4.30 p.m. (Ordinary Meeting.) LIEUT.-COLONEL W. A. TILNEY, F.R.G.S., F.R.A.S., late 17th Lancers, "The Art of Finding your Way at Night without a Compass." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday afternoon, November 29th, DR. WALTER ROSENHAIN, F.R.S., delivered the first lecture of his course on "Optical Glass."

The lectures will be published in the *Journal* during the Christmas recess.

COLONIAL SECTION.

Tuesday afternoon, November 30th; SIR HENRY A. BLAKE, G.C.M.G., in the chair. A paper on "Recent Developments in Jamaica: Internal and External," was read by SIR SYDNEY OLIVIER, K.C.M.G., late Governor of Jamaica.

The paper and discussion will be published in a subsequent number of the *Journal*.

JUVENILE LECTURES.

Two of the Members of the Council—Professor John Millar Thomson, LL.D., F.R.S., and Mr. James Swinburne, F.R.S. — have kindly undertaken to deliver the Juvenile Lectures this year. Professor Thomson will give the first lecture on Wednesday afternoon, January 5th, at 3 p.m., his subject being "Crystallisation." Mr. James Swinburne will give the second on Wednesday, January 12th, at 3 p.m.; his subject will be "Science of some Toys." Both lectures will be very fully illustrated with experiments.

Special tickets are required for these lectures. They can be obtained, when ready, on application to the Secretary.

A sufficient number of tickets to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply for them at once.

PROCEEDINGS OF THE SOCIETY.

THIRD ORDINARY MEETING.

Wednesday, December 1st, 1915; SIR WILLIAM J. COLLINS, K.C.V.O., M.S., F.R.C.S., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Fakira, Meherali Mahomed, 13, Esplanade-road, Bombay, India.

Lyster, Anthony George, M.Eng., M.Inst.C.E., 2, Queen Anne's-gate, S.W.

Phelps, William Heath, J.P., Park House, 13, Park-street, Calcutta, India.

Stewart, William Arnold, Bulak Technical School, Cairo, Egypt.

The following candidates were balloted for and duly elected Fellows of the Society:—

Alexander, Alexander, National Gum and Mica Company, 59th Street and 11th Avenue, New York City, U.S.A.

Ardaseer, J. Grenville, Worli Hill, Bombay, India, and Olney House, Richmond, Surrey.

Audy, Alphonse William, 33, Civil Lines, Poona, India.

Baldwin, Mrs. Edith Brake, 24, Avenue-road, Leamington Spa.

Basu, Narendra Kumar, 99, Upper Circular-road, Calcutta, India.

Bhattacharyya, Jyotischandra, M.A., B.L., Purnea Bihar, India.

Bloxam, John Astley, F.R.C.S., J.P., The Old Malt House, near Maidenhead, Berks.

Buckley, Edward S., jun., 2039, Sansom-street, Philadelphia, Pa., U.S.A.

Cardona, Joseph M., 1917, Catamarca-street, Rosario, Argentine Republic.

Chance, Clinton Frederick, B.A., 12, Arthur-road, Edgbaston.

Chu Ju, General, Chiang Chun Yamen, Chekiang, China.

Clark, The Hon. Sir William Henry, K.C.S.I., C.M.G., Windcliffe, Simla, India.

Cochin, The Diwan of (Joseph W. Bhore, B.A., I.C.S.), Ernakulam, Cochin, South India.

Davson, Edward R., 20, Ennismore-gardens, S.W.

Dholpur, His Highness the Maharaj Rana of, Dholpur State, India.

Evans, Gerald A., LL.B., J.P., P.O. Box 151, Pietersburg, N. Transvaal, South Africa.

Furness, Horace Howard, jun., 2034, De Lancey-place, Philadelphia, Pa., U.S.A.

Gibbs, A. E., Pennsylvania Salt Manufacturing Company, Greenwich Point, Philadelphia, U.S.A.

Gwalior, Major-General His Highness The Maharaja of (Sir Madho Rao Sindhia Bahadur), G.C.S.I., G.C.V.O., LL.D., A.D.C., Madho Bilas, Sipri, Gwalior, India.

Ingels, Lionel, 5, Grosvenor House, Calcutta, India.

Lambagraon, Lieut.-Colonel the Hon. Raja Jai Chand of, C.S.I., Lambagraon, Kangra District, Punjab, India.

Leech, Arthur John, The Palms, College-road, Madras, India.

Liebert, William Ernest Cato, Messrs. Huttenbach Bros. & Co., Penang, Straits Settlements.

Lord, James Spain, Dover House, Bridge-street, Canterbury.

McCorry, Joseph James, 73, University-avenue, Belfast.

Miln, David Anderson, LL.B., M.A. (Edin.), 30, Greencroft-gardens, South Hampstead, N.W.

Mitchell, Alfred H., M.I.Mech.E., Port of London Authority, Elevator Dock, Silvertown, E.

Musgrave, Henry Arthur Fitzherbert, United Service Club, Calcutta, India.

Naidu, P. N. Muthuswami, B.A., Pagadala Bagh, Saidapet, Madras, India.

O'Callaghan, Major-General Sir Desmond D. T., R.A., K.C.V.O., 53, Iverna-court, Kensington, W.

Pite, Professor Arthur Beresford, F.R.I.B.A., 21, Willow-road, Hampstead, N.W.

Renult, William, 141, Broadway, New York City, U.S.A.

Showers, St. George, 32, Elm Park-road, S.W.

Singh (of Kapurthala), Sirdar Charanjit, Chadwick, Simla, India.

Singh, Rai Bahadur Choudri Amar, P.O. Pali, Dist. Bulandshare, United Provinces, India.

Smith, Alexander, 21, Oakshaw-street, Paisley, Scotland.

Smith, Lieut.-Colonel Thomas, V.D., The Muir Mills Co., Ltd., Cawnpore, India.

Sundaracharlu, S. K., M.A., Tahsildar, Tindivanam, South India.

Thorne, Mathew Henry, Rua Padrão, Vallongo, Portugal.

Vanderlip, Frank Arthur, A.M., LL.D., National City Bank, New York City, U.S.A.

The Chairman, in opening the meeting, announced that the Master of Christ's College, Cambridge, was unfortunately too ill to read his paper himself. Thanks, however, to the kind intervention of Mr. F. M. Howlett, who was Pathological Entomologist to the Government of India, the members would have the benefit of hearing Dr. Shipley's paper read and seeing the slides which illustrated it. Mr. Howlett was an excellent substitute for the original lecturer, as he had a world-wide reputation on the subject of parasitology.

The paper read was—

INSECTS AND WAR.

By Arthur Everett Shipley, Sc.D., F.R.S.,
Master of Christ's College, Cambridge.

The insects which prove such a nuisance to the fighter in time of war are the insects which equally affect man in time of peace. But owing to the different circumstances which arise when men are at war their effects are more violent and more persistent. Roughly speaking, we can divide these insect pests into two categories—(1) those which pierce the skin of men or of animals on which the soldier is to a great extent dependent, for instance, the horse; and (2) those which interfere with his food supplies. The latter, again, fall into two categories—(*a*) those which materially and substantially diminish that food supply, and by leaving their larvæ behind in the diminished stock render the food unpalatable; and (*b*) those which infect the food supply with pathogenic germs, such as those of enteric fever.

Amongst the insects which bite man, or, rather, pierce his skin, and which in times of peace can be kept in some sort of control, is the louse. In times of war, when men are herded together, with little or no opportunity of changing their linen, or washing, the louse is sure to appear and probably spread rapidly.

We will confine our attention to the genus *Pediculus*—*P. capitis*, the head-louse, and *P. vestmenti*, the body-louse. They do not arise, as the uninformed think, from dirt, though they flourish best in dirty surroundings. No specimen of *P. vestimenti* exists which is not the direct product of an egg laid by a mother-louse and fertilised by a father-louse. In considerable collections of men drawn from the poorer classes, some unhappy being or other—often through no fault of his own—will turn up in the community with lice on him, and these swiftly spread to others.

Like almost all animals lower than the mammals, the male of the body-louse is smaller and feebler than the female. The former attains a length of about 3 mm., and is about 1 mm. broad. The female is about 3·3 mm. long and about 1·4 mm. broad. It is rather bigger than the hair-louse, and its antennæ are slightly longer. It so far flatters its host as to imitate the colour of the skin upon which it lives; and Andrew Murray gives a series of gradations between the black louse of the West African and Australian native, the dark and smoky louse of the Hindu, the orange of the Africander and of the Hottentot, the yellowish-brown of the North and South American Indians, and the paler brown of the Esquimo, which approaches the light dirty-grey colour of the European parasites—

"As plump an' grey as onie grozet,"

as Burns has it.

The body-louse was the species dealt with in the recent observations undertaken by Mr. C. Warburton in the Quick Laboratory at Cambridge, at the request of the Local Government Board, the authorities of which were anxious to find out whether the flock used in making cheap bedding was instrumental in distributing vermin. Mr. Warburton at once appreciated the fact that he must know the life-history of the insect before he could successfully attack the problem put before him. At an early stage of his investigations he found that *P. vestimenti* survives longer under adverse conditions than *P. capitis*, the head-louse.

The habitat of the body-louse is that side of the underclothing which is in contact with the body. The louse, which sucks the blood of its host at least twice a day, is, when feeding, always anchored to the inside of the underclothing of its host by the claws of one or more of its six legs. Free lice are rarely found on the skin in western Europeans. But the underside of a stripped shirt is often alive with them.

After a great many experiments, Mr. Warburton succeeded in rearing these delicate insects, but only under certain circumscribed conditions; one of which was their anchorage in some sort of flannel or cloth, and the second was proximity to the human skin. He anchored his specimens on small pieces of cloth, which he interned in small test-tubes plugged with cotton-wool, which did not let the lice out, but did let air and the emanations of the human body in. For fear of breakage the glass tube was enclosed in an outer metal tube, and the whole was kept both night and day near the body. Two meals a day were necessary to keep the lice alive. When feeding, the pieces of cloth, which the lice would never let go of, were placed on the back of the hand, hence the danger of escape was practically *nil*, and once given access to the skin the lice fed immediately and greedily.

His success in keeping lice alive was but the final result of many experiments, the majority of which had failed. Lice are very difficult to rear. When you want them to live they die, and when you want them to die they live and multiply exceedingly. A single female but recently matured was placed in a test-tube, and a male admitted to her on the second day. The two paired on the sixth day, and afterwards at frequent intervals. Very soon after pairing an egg was laid, and during the remaining twenty-five days of her life the female laid an average of five eggs every twenty-four hours. The male died on the seventeenth day, and a second male was then introduced, who again paired with the female. The latter, however, died on the thirtieth day, but the second male survived.

The difficulty of keeping the male and female alive was simple compared with the difficulty of rearing the eggs. Very few hatched out. The strands of cloth upon which they were laid had been carefully removed and placed in separate tubes, at the same time being subjected to different temperatures. It was not, however, until the eggs were left alone undisturbed in the position where they had been laid and placed under the same conditions that the mother lived in that eight, and only eight, of the twenty-four eggs laid on the cloth hatched out after an incubation period of eight days. The remaining

sixteen eggs were apparently dead. But the tube in which they were was then subjected to the normal temperature of the room at night (on occasions this fell below freezing-point), and after an incubation period of upwards of a month six more hatched out. Hence it is obvious that, as in the case of many other insects, temperature plays a large part in the rate of development, and it becomes clear that the eggs or nits of *P. vestimenti* are capable of hatching out up to a period of at least from thirty-five to forty days after they are laid.

Difficult as it was to keep the adults alive, and more difficult as it was to hatch out the eggs, it was most difficult to rear the larvæ. Their small size made them difficult to observe, and, like most young animals, they are intolerant of control, apt to wander and explore, and less given to clinging to the cloth than their more sedentary parents. Naturally, they want to scatter, spread themselves, and pair.

Like young chickens, the larvæ feed immediately on emerging from the egg. They apparently moult three times, at intervals of about four days, and on the eleventh day attain their mature form, though they do not pair until four or five days later.

Mr. Warburton summarises the life-cycle of the insects, as indicated by his experiments, as follows: Incubation period, eight days to five weeks; from larva to imago, eleven days; non-functional mature condition, four days; adult life—male, three weeks; female, four weeks.

But we must not forget that these figures are based upon laboratory experiments, and that under the normal conditions the rate may be accelerated. From Mr. Warburton's experience it is perfectly obvious that, unless regularly fed, body-lice very quickly die. Of all the verminous clothing sent to the Quick Laboratory, very little contained *live* vermin. The newly-hatched larvæ perish in a day and a half unless they can obtain food. These facts regarding the life-history of body-lice were fully confirmed by Dr. Fantham when working on the protozoal parasites of lice.

With regard to the head-louse—

> "Ye ugly, creepin', blastit wonner,
> Detested, shunn'd by saunt an' sinner,"

it is smaller than the body-louse, and is of a cindery-grey colour. The female measures 1·8 mm. in length and 0·7 mm. in breadth. Like the body-louse, it varies its colour somewhat with the colour of the hair on the different branches of the human race. It lives amongst the hair of the head of people who neglect their heads; it is also, but more rarely, found amongst the eyelashes and in the beard. The egg, which has a certain beauty of symmetry, is cemented to the hair, and at the end of six days the larvæ emerge, which, after a certain number of moults, become mature on the eighteenth day. The methods adopted by many natives of plastering their hair with coloured clay, or of anointing it with ointments, probably guards against the presence of these parasites. The Spartan youths, who used to oil their long locks before going into battle, may have feared this parasite. Some German soldiers, before going to war, shave their heads; thus they afford no nidus for *P. capitis*. The wigs worn in the late seventeenth and at the beginning of the eighteenth centuries undoubtedly owed something to the difficulty of keeping this particular kind of vermin down. The later powdering of the hair may have been due to the same cause.

P. capitis is in wartime less important than *P. vestimenti*. The former certainly causes a certain skin trouble, but the latter not only affords constant irritation, but, like most biting insects, from time to time conveys most serious diseases. *P. vestimenti* is known to be the carrier of typhus. This was, I believe, first demonstrated in Algeria, but was amply confirmed last year in Ireland, when a serious outbreak of this fever took place, though little was heard of it in England. Possibly, *P. capitis* also conveys typhus, but undoubtedly both convey *Spirochaeta recurrentis*—the cause of relapsing or recurrent fever. The irritation due to the body-louse weakens the host and prevents sleep, besides which there is a certain psychic disgust which causes many officers to fear lice more than they fear bullets. Also by rubbing or scratching the lice may be crushed on the skin. The germs of disease within them may thus be inoculated directly into the blood through the surface of the skin damaged by the scratch. Soldiers should, further, always avoid touching their eyes after scratching insect-bites. Lice are the constant accompaniment of all armies; and in the South African War as soon as a regiment halted they stripped to the skin, turned their clothes inside out and picked the *Anoplura* off. As a private said to me: "We strips and we picks 'em off and places 'em in the sun, and it kind o' breaks the little beggars' 'earts!"

There were serious outbreaks of typhus during the recent Balkan wars among the combatants, prisoners, and refugees. The epidemics were spread by lice. Again, typhus and relapsing fever are endemic in various areas along the

eastern front of the present theatre of war, and are even now causing trouble in Serbia.

Another insect which pierces the skin of man and destroys the continuity of his integument is the bed-bug, *Cimex lectularius.*

The common bed-bug seems to have arrived in England about the same time as the cockroach, that is, over four hundred years ago, early in King Henry VIII.'s reign. Apparently it came from the East, and was for many years confined to seaports and harbours. It seems to have been first mentioned by playwriters towards the beginning of the seventeenth century. The sixteenth-century dramatists could never have resisted mentioning the bug had it been in their time a common household pest. It would have appealed to their sense of humour.

How the insect got the name of "bug" is unknown. It has been suggested that the Old English word "bug," meaning a ghost or phantom which walked by night, has been transferred to *Cimex.* This may be so, but the "Oxford English Dictionary" tells us that proof is lacking.

The insect is some 5 mm. in length, and about 3 mm. in breadth, and is of a reddish- or brownish-rusty colour, fading into black. Its body is extraordinarily flattened, so that it can readily pass into chinks or between splits in furniture and boarding, and this it does whenever daylight appears, for the bug loves darkness rather than light. The head is large, and ends in a long, piercing, four-jointed proboscis, which forms a tube with four piercing stylets in it. As a rule, the proboscis is folded back into a groove, which reaches to the first pair of legs on the under surface of the thorax. This folding back of the proboscis gives the insect a demure and even a devout expression; it appears to be engaged in prayer, but a bug never prays. The head bears two black eyes and two four-jointed antennæ. Each of the six legs is provided with two claws, and all the body is covered with fairly numerous hairs. The abdomen shows seven visible segments and a terminal piece.

The bug has no fixed period of the year for breeding; as long as the temperature is favourable and the food abundant generation will succeed generation without pause. Should, however, the weather turn cold the insects become numbed and their vitality and power of reproduction are interrupted until a sufficient degree of warmth returns.

Like the cockroach, the bed-bug is a frequenter of human habitations, but only of such as have reached a certain stage of comfort. It is said to be comparatively rare in the homes of savages; but it is only too common in the poorer quarters of our great cities. The iron bedstead which has so rapidly replaced the wooden bedstead was at one time thought to render the bug's position untenable. This is not so. Bugs will shelter in its metallic crevices almost as comfortably as in the wooden chinks of its predecessor. Its presence does not necessarily indicate neglect or want of cleanliness. It is apt to get into trunks and luggage, and in this way may be conveyed even into the best-kept homes. It is also very migratory, and will pass readily from one house to another, and when an infested dwelling is vacated these insects usually leave it for better company and better quarters. Their food supply being withdrawn, they make their way along gutters, water-pipes, etc., into adjoining and inhabited houses. *Cimex* is particularly common in ships, especially emigrant ships, and, although unknown to the aboriginal Indians of North America, it probably entered that continent with the "best families" in the "Mayflower."

Perhaps the most disagreeable feature of the bed-bug is that it produces an oily fluid which has a quite intolerable odour; the glands secreting this fluid are situated in various parts of the body. The presence of such glands in free-living Hemipterous insects is undoubtedly a protection—birds will not touch them. One, however, fails to see the use of this property in the bed-bug. At any rate, it does not deter cockroaches and ants, as well as other insects, from devouring the *Cimex.* There is a small black ant in Portugal which is said to clear a house of these pests in a few days; but one cannot always command the services of a small black Portuguese ant.

Another remarkable feature is that the insect has no wings, although in all probability its ancestors possessed these useful appendages. As the American poet writes—

> "The Lightning-bug has wings of gold,
> The June-bug wings of flame,
> The Bed-bug has no wings at all,
> But he *gets* there all the same!"

The power of "getting there" is truly remarkable. Man, their chief victim, has always warred against bugs, yet, like the poor, bugs "are always with us." I heard it stated, when I was living in Southern Italy, that if you submerged the legs of your bed in metal saucers full of water and placed the bed in the centre of the room,

the bugs will crawl up the wall, walk along the ceiling and drop on to the bed and on to you. Anyhow, whether this be so or not, there is no doubt that these insects have a certain success in the struggle for life, and only the most systematic and rigorous measures are capable of ridding a dwelling of their presence.

The eggs of the bed-bug are pearly white, oval objects, perhaps 1 mm. in length. At one end there is a small cap surrounded by a projecting rim, and it is by pushing off this cap, and through the orifice thus opened, that the young bug makes its way into the outer world after an incubation period of a week or ten days. There is no metamorphosis—no caterpillar and no chrysalis stages. The young hatch out in structure miniatures of their parents, but in colour they are yellowish-white and nearly transparent. The young feed readily, and feeding takes place between each moult, and the moults are five in number, before the adult imago emerges. This it does about the eleventh or twelfth week after hatching. These time-limits depend, however, upon the temperature after hatching, and the rate of growth depends not only upon the temperature, but also upon the amount of food.

When bred artificially, and under good conditions, the rate of progress can be "speeded up" so that the eggs hatch out in eight days, and every following moult takes place at intervals of eight days, so that the period from egg to adult can be run through in as short a time as seven weeks. Unless fed after each moult, the following moult is indefinitely postponed. Hence it follows that in the preliminary stages bugs must bite their hosts five times before the adult form emerges, and the adult must, further, have a meal before she lays her eggs. The eggs are deposited in batches of from five to fifty in cracks and crevices, into which the insects have retired for concealment.

Bugs can, however, live a long time without a meal. Cases are recorded in which they have been kept alive for more than a year incarcerated in a pill-box. When the pill-box was ultimately opened, the bugs appeared to be as thin as oiled paper, and almost so transparent that you could read the *Times** through them; but even under these conditions they had managed to produce offspring. De Geer kept several alive in a sealed bottle for more than a year. This power of existing without food may explain the fact that vacated houses occasionally swarm with bugs even when there have been no human beings in the neighbourhood for many months.

* Only the larger print, such as the leading articles and letters from admirals.

The effect of their bite varies in different people. As a rule, the actual bite lasts for two or three minutes before the insect is gorged, and at first it is painless. But very soon the bitten area begins to swell and to become red, and at times a regular eruption ensues. The irritation may be allayed by washing with menthol or ammonia.

The bed-bug has been accused of conveying many diseases. How far it does this in nature seems uncertain. But it certainly contains certain pathogenic spirochaetes, and monkeys have been infected in the laboratory with these.

In India the bed-bug is under suspicion of spreading *kala-azar*, or "black fever." Other insects probably convey similar diseases in various parts of the tropics and sub-tropics, as is indicated by the recent experiments of Professor Laveran and Dr. Franchini in Paris, and Drs. Fantham and Porter in Cambridge. Whether bugs be guilty of these crimes or not, they are the cause of an intense inconvenience and disgust, and should, if possible, be dealt with drastically. At the present time there are rumours that some of our largest camps are infested with these insects, and there seems no doubt that some of the prisoners and refugees to this country have brought their fauna with them, and this fauna is very capable of spreading in concentration camps. The erection of wooden huts—no doubt a pressing necessity—affords convenient quarters for these pests.

A third biting insect is the flea.

Fleas are temporarily parasitic on many mammals and birds, but some mammals and some birds are much freer from fleas than others. As the flea is only on its host for part of the time, it has to put in the rest of its existence in some other place, and this, in the case of the human flea, is usually the floor, and in the case of bird-fleas the nest; from these habitats they can easily regain their hosts when the latter retire to rest. But larger numbers of Ungulates—deer, cattle (except when domesticated), antelopes, goats, wild boars—usually sleep in different places each recurrent night, and to this is probably due the fact that, with the exception of two rare species—one taken in Northern China and the other in Transcaucasia—the Ungulates have furnished descriptive science with no fleas at all. Both of these Ungulate fleas are allied to the burrowing-fleas, or "chigoes."

I know none of my hearers will believe me

when I say that the same is true of monkeys; but I do this on the undoubted authority of Mr. Harold Russell, who has recently published a charming little monograph on these lively little creatures. Monkeys in nature are cleanly in their habits; and although in confinement occasionally a human flea attacks them, and although a chigo bores sometimes into the toes of a gorilla or chimpanzee, "speaking generally, it may be said that no fleas have been found truly parasitic on monkeys." Whatever the monkeys are looking for, it is not the fleas. What they seek is, in effect, little scabs of scurf, which are made palatable to their taste by a certain sour sweat.

As a rule, each host has its own species of flea, but though, for the most part, *Pulex irritans* is confined to man it is occasionally found on cats and dogs, whilst, conversely, the cat and dog fleas (*Ctenocephalus felis* and *Ct. canis*) from time to time attack man.

The bite of the flea is accompanied by the injection of the secretions of the so-called salivary glands of the insect, and this secretion retards the coagulation of the victim's blood, stimulates the blood-flow, and sets up the irritation we have all felt.

It is only a few years ago that the spread of bubonic-plague was associated first with rats, and then with rat-fleas; and at once it became of enormous importance to know which of the numerous species of rat-fleas would attack human beings. The Hon. Charles Rothschild, who has accumulated a most splendid collection of preserved fleas in the museum at Tring, had some years ago differentiated from an undifferentiated assemblage of fleas a species first collected in Egypt, but now known to be the commonest rat-flea in all tropical and subtropical countries. This species, *Xenopsylla cheopis*—and to a lesser extent *Ceratophyllus fasciatus*—unfortunately infests and bites man. If they should have fed upon a plague-infected rat and subsequently bite man, their bites communicate bubonic plague to human beings. Plague—the Old English "Black Death"—is a real peril in our armies now operating in Asia and in certain parts of Africa.

Just as some fleas attack one species of mammal or bird and avoid closely-allied species, so the human flea has its favourites and its aversions. There is a Turkish proverb which says, "An Englishman will burn a bed to catch a flea," and those who suffer severely from flea-bites would certainly do so. The courage of the Turk in facing the flea, and even worse dangers, may be, as the schoolboy wrote, "explained by the fact that a man with more than one wife is more willing to face death than if he had only one." But there are persons even a flea will not bite. Mr. Russell has reminded us, in his preface, of the distinguished lady who remarked, "*Quant à moi ce n'est pas la morsure, c'est la promenade!*"

There are one or two structural features in a flea which are peculiar, the most remarkable being that, unlike most other insects, it is much taller than it is broad. As a rule, insects—such as a cockroach, the bed-bug, or a stag-beetle—are like skates, broader than they are tall; but the flea has a laterally compressed shape, like a mackerel or a herring. Then, again, the three segments or rings which come after the head are not fused into a solid cuirass or thorax as they are in the fly or the bee, but they are movable one on the other. Finally, it is usual in insects for the first joint of the leg to be pressed up against and fused with those segments of the body that bear them; but in the flea, not only is this joint quite free, but the body segment gives off a projection which stretches out to bear the leg. Thus the leg seems, unless carefully studied, to have an extra joint and to be—as, indeed, it is—of unusual length. They certainly possess unusual powers of jumping—as Gascoigne, a sixteenth-century poet (1570–78) writes: "The hungry fleas which frisk so fresh."

The male, as is so often the case amongst the invertebrata, is much smaller than the female. The latter lays at a time from one to five minute, sticky, white eggs, one-fortieth of an inch long by one-sixtieth broad. They are not laid on the host, but in crevices between boards, on the floor, between cracks in the wainscoting, or at the bottom of a dog-kennel or in birds'-nests. Mr. Butler recalls the case of a gentleman who collected on four successive mornings sixty-two, seventy-eight, sixty-seven, and seventy-seven cat-fleas' eggs from the cloth his cat had slept upon. Altogether 284 eggs in four nights. The date of hatching varies very much with the temperature. *Pulex irritans* takes half as long again—six weeks instead of four—to become an adult imago in winter as it does in summer. But in India the dog-flea will complete its cycle in a fortnight.

When it does emerge from the egg the larva is seen to be a whitish segmented little grub without any limbs, but with plenty of bristles, which help it to move about; this it does very actively. There are two small antennæ and a

pair of powerful jaws, for the larva does not take liquid food, but eats any scraps of solid organic matter which it comes across; dead flies and gnats are readily devoured. The larva casts its skin several times, though exactly how often it moults seems still uncertain.

After about twelve days of larval existence it spins itself a little cocoon in some sheltered crevice, and turns into a whitish inert chrysalis or pupa. During its pupal existence it takes, of course, no food, but it grows gradually darker, and after undergoing a tremendous internal change, breaking down its old tissues and building up new ones, the chrysalis-case cracks and the adult flea jumps out into the world.

Perhaps the most important of biting insects is the mosquito, certain species of which convey malaria—a disease which has probably played a bigger part in the history of the world than that conveyed by any other insect. As in most other biting insects, the piercing organ consists of a tube, or gutter, in the hollow of which lie certain chitinous rods, with saw-like edges, and the outer gutter encloses an inner gutter facing the other way, up which ultimately the blood the mosquito sucks will flow. In the mosquito there is also a median structure, like a double-edged sword, the prolongation of the lower lip. This is traversed by the duct, from which flows the so-called saliva of the insect. This saliva carries with it the microscopic, unicellular animals which cause malaria, and down this minute, microscopic duct has flowed the fluid which has altered the fate of continents and played a conspicuous part in destroying the civilisations of Greece and Rome.

The female is very voracious, but the mouth parts of the male are not strong enough to penetrate the human skin; it has to be content with a diet of vegetable juice. Still, the female will suck up blood till all the cracks between its chitinous armour are incarnadined. It is thought by some that no eggs are laid unless a meal of blood has been taken. This, however, does not seem to have been definitely established.

Anopheles maculipenis is the chief carrier of malaria, and is found very widely distributed throughout the world. As a rule, individuals do not wander very far on their own account, but they can be blown considerable distances by a wind, and they have a habit of travelling about in trains and ships, but not, perhaps, to the same extent as *Stegomyia calopus*, which conveys the yellow fever. The female hibernates throughout the winter, and has been found under the frozen snows of Siberia, mingled with the moss and snow. In England they are frequently found in old out-houses, deserted cellars, and unused farm buildings. They have generally left their winter quarters by May, when they begin to lay their eggs, and this they do early in the morning. In temperate climates there are three or four generations during the summer, the latest being through September and October. It has been calculated that if the number of eggs laid by the female be 150, the numbers of the descendants by the fourth generation would amount to over thirty million. This may account for the enormous numbers in which mosquitoes are found in places like Finland, Siberia, and other northern climates.

The eggs are rather like little lifeboats, with a floating ridge on each side which keeps the ova the right way up. They are black with a certain iridescence, and, like all other objects floating on the surface, they tend to form star-like or reticulated patterns, and if they are near where the water touches the edge of the vessel they are drawn a little way up. But the head-end of the egg always points downwards, so that should the larva emerge whilst in this position it at once gets into its proper element. The larva emerges during the second or third day after oviposition, according to the temperature. It is one of the most interesting aquatic larvæ we know. It hangs on the lower surface of the surface-film by a series of palmate hairs; and by its open stigmata, which pierce the surface-film, it puts the interior of the body in connection with the atmosphere. The head is provided on its under surface with two moustache-like structures, which constantly sweep the under surface of the surface-film, sweeping the organic matter which may have floated up there into the larva's mouth. Since the dorsal surface of the larva is uppermost, and the brushes are on the ventral surface of the head, when feeding the head is turned round at an angle of 190°, and this is done with so much precision that you can almost hear it click. The pupa is also attached to the surface-film by its breathing trumpets, and it is these stigmata, or breathing pores, that are the weak point in the structure of these diptera, since it is easy by brushing paraffin through the water to establish a thin surface-film of oil, which cuts both larva and pupa off from the necessary oxygen, and so kills them.

Stegomyia is somewhat different in appearance. It is especially a haunter of the dwellings of man, and it frequents ships. Its egg is covered with a series of reticulations containing air

which enables it to float, and the larvæ, unlike those of *Anopheles*, but like those of *Culex*, hang down into the water by single respiratory stigmata.

They seem to bite all the twenty-four hours round, and although we have not been able to isolate the organisms which cause yellow fever, there is no doubt the fever is conveyed by this species of mosquito.

There are also a number of biting flies, such as the *Tsetse* fly, which sucks blood greedily, and the blood-sucking maggot of a fly, a larva of *Auchmeromyia luteola*, which chiefly affects natives sleeping on mats in Central sub-tropical Africa, and there are, of course, many flies which injure horses and cattle, and materially diminish the value of their hides. Leather plays a very conspicuous part in warfare. The deterioration of hides owing to the warble fly very materially affects the leather market, not to mention the fact that when cattle are attacked the meat is also seriously damaged.

Let us turn now for a few minutes to the insects that affect the food of man. Both the house-fly and the blue-bottle fly act in this manner.

In our country house-flies usually begin to breed in June and July, continuing well on into October if the weather be but warm. Their greatest activity is, however, in the hotter month of August and the beginning of September. But in warm stables, restaurants, and kitchens, flies are able to reproduce the whole year round. A single fly will deposit at one time 100 to 150 eggs, and in the course of her summer life may produce five, or even six, batches of ova of this size. The eggs are pearly white, elongated structures, with two converging lines, along which the egg-case will ultimately split to give exit to the larva. The eggs are laid, by means of a long ovipositor, a little way beneath the surface of the dung-heap in a position where they will not readily be dried up. In favourable conditions the eggs hatch in from eight to twenty-four hours.

The larvæ are legless, tapering towards the head, which bears a pair of breathing-holes, or spiracles; their bodies are much stouter towards the hinder end. On the whole they are white, unpleasant-looking maggots, called by fresh-water fishermen "gentles." By contracting and expanding its body it pushes its way through the moist, semi-liquid surroundings. The skin is usually moulted some twenty-four hours after birth, but all these time-limits depend much upon the temperature and favourable conditions. With normally high temperatures—say, with 86° to 95° F.—the larva will become fully grown in five or six days. The third and final stage, after the second moult or ecdysis, lasts three days, and when fully grown the maggots are about half an inch in length. Externally, twelve segments are visible, but the internal anatomy shows that thirteen are really present, though one is almost "masked."

It is only during these larval stages that the insect grows, and it is never more bulky than in the third larval stage. Now it leaves the moist situation in which it has flourished, and, crawling through the manure, seeks some dry or sheltered corner near the surface of the manure heap. For a time it rests, and then after an hour or two's quiescence it retracts its anterior end and assumes a barrel-shaped outline, its creamy white colour slowly changing to a mahogany brown. The larval skin forms the pupa-case, and within this pupa-case the body of the larva undergoes a wonderful change, far greater than ever human beings undergo at the time of puberty. Many of its organs are disintegrated and re-formed, and in the course of three or four days the white, legless, repellent maggot, who "loves darkness rather than light," is changed into a lively, flying insect, seeking "a place in the sun" and the companionship of man. As the Frenchman said of the pig which goes into one end of the machine in the Chicago meat-factory as live pig and comes out at the other end in the form of sausages, "*Il est diablement changé en route.*"

In a very short time after leaving the pupa-case the adult fly has stretched her wings, the chitin of her body has hardened, and she flies away "on her several occasions."

Flies become sexually mature in a week or ten days after emerging from the chrysalis-case, and are capable of depositing their eggs four days after mating, so that if the conditions be indeed favourable the whole development from the egg to the perfect fly may be accomplished in nine or ten days, and the second generations are able to lay their eggs ten days later. The appalling fecundity of such an insect explains the fact that in the hotter parts of the world nearly every edible thing seems to be covered with flies.

The proboscis of a fly can only suck up liquid food; and when we see it feeding on solid substances, such as sugar, it has really dissolved the sugar by depositing some saliva on it, and is sucking up the sugary solution so produced. It not infrequently regurgitates its food in a spherical drop, which it generally reabsorbs.

As we have seen, flies are very susceptible to temperature, and with the approach of cold weather they seem to die. We used to think that some, in a state of suspended animation, "carried on" through the winter months. This is, however, "non-proven." Many of them undoubtedly die in the autumn, as bees die, of old age. They are literally worn out. But a great number fall victims to a parasitic fungus called *Empusa*. Flies killed by this fungus are frequently to be seen in autumn, hanging dead on windows, etc., surrounded by a little whitish, powdery ring of spores formed by the fungus.

Flies, like many other common insects, are extremely difficult to keep alive in captivity, and few have succeeded in rearing them for more than a month or two. At one time, as we have said, it was thought that those flies which survive the winter were fertilised females of the younger broods, and that during the winter they subsisted on their "fat bodies."

Doubt, however, has recently been thrown on this theory, and at the present time, as the Local Government Board states, the manner in which the interval between one fly season and the next is bridged over still remains unsolved.

Flies breeding in horse manure, or coming direct from infected organic matter, affect the jam, the milk and other food of the soldier. Until the perfecting of the anti-typhus inoculation was effected, in times of war typhoid killed more soldiers than bullets. Infantile diarrhœa is another disease associated with *Musca domestica*, so are ophthalmia and anthrax.

It will be noted that the fly acts simply as an inoculating agent. The germs which are conveyed are mostly bacteria, and they do not necessarily undergo any change in connection with the body of the house-fly.

Next we come to a series of insects which affect the food of soldiers and sailors. One is the flour-moth, *Ephestia kuhniella*, whose larva burrows through the soldiers' biscuit and not only consumes a considerable portion of it, but renders it so unpalatable that Sergeant Daniel Nicol, of the 92nd Gordon Highlanders, tells us that, during the Expedition to Egypt in 1801, "some vessels were despatched to Macri Bay for bullocks, and others to Smyrna and Aleppo for bread, which was furnished us by the Turks—a kind of hard dry husk. We were glad to get this, as we were then put on full rations, and our biscuits were bad and full of worms; many of our men could only eat them in the dark." The biscuits become infected during the cooling which takes place between the baking and the packing. The adult insect, *E. kuhniella*, is a perfect nuisance in flour-mills. So persistent and numerous are these moths at times that they clog the rollers with their cocoons, and sometimes completely stop them. The webbing of the elevators in the mills gets covered with them, and with their silky skeins, and then the elevators stop working. They mat together the flour and meal with their silken excreta, and so uniform is the temperature of the mill, and so favourable to the life of the insect, that they complete their life-cycle in this country in two months, and in the warmer parts of America even more rapidly. In well-heated mills the proceeding is continuous, so that six generations at least may be produced each year.

Now that the war is spreading in the Near East, a word or two should also be said about an allied species of insect, *Ephestia cautella*, which infests at times 50 per cent. of the figs of the East. It is a moth which is spread all over the world, and is catholic in its taste, since it flourishes on rice, bran, dried apples, maize and a great many more or less nutritious foods. It lays its eggs in the figs whilst they are being dried in the sun. From the egg a small maggot emerges and whoever eats dried figs must at times come across them. These larvæ, which emerge towards the end of September or October, render a voyage on a fig-laden ship very unpleasant, as they crawl about the ship before pupating.

Finally, we must not forget the biscuit "weevil," so familiar to us in Marryat's novels. And the first thing to notice about it is that it is not a weevil at all. It is in truth known as *Anobium paniceum*, and is closely allied to *A. striatum*, which makes the little round holes in worm-eaten furniture so cleverly imitated by second-hand furniture dealers. There is hardly anything the larva of this insect will not eat, from cayenne pepper to opium, from tablets of compressed meat to Arabic manuscripts. It is, however, to-day far less common than in the past through the invention of the biscuit-tin, a comparatively modern discovery, which has done much to interfere with its plans.

DISCUSSION.

The Chairman (Sir William J. Collins, K.C.V.O., M.S., F.R.C.S.), in opening the discussion, said he was sure the audience would agree with him that Mr. Howlett had very ably undertaken the delivery and illustration of a lecture for which he was not personally responsible. Although he might not hold identical views in every respect

with the author of the paper, he had informed him (the Chairman) that, as a master of the subject, he was perfectly willing and able to answer any questions that anybody present chose to ask. As he listened to the paper he was reminded of a saying of, he thought, the late Sir William Gull, who once made the observation in his emphatic and rather Napoleonic way, that he always observed that new discoveries came out of the residuum of knowledge. That was true of the subject-matter of the paper. He believed Gull illustrated it from the way in which Professor Charcot, when attached to an infirmary in Paris, drew the most illuminating discoveries out of what was practically the dustbin for the mental and moral rubbish of Paris, and out of that elucidated the studies of the diseases of the nervous system. So, on the present occasion, out of matter that had been despised, neglected, and treated as hardly suitable, and perhaps too indelicate for polite ears and polite conversation, had come some of the most illuminating discoveries in regard to the origin of infectious diseases or the mode of their propagation. It had been said that the ancients attributed epidemics to the interventions of the Infinitely Great. It might be said that the moderns attributed at any rate many epidemic diseases to the operations and machinations of the Infinitely Little. This was the day of the infinitely little: the infinitely little had come into its own. In the case of plague, typhus fever, malaria, yellow fever, and perhaps blackwater fever, there was a good amount of evidence accumulating to show that the parasitic arthropods were instrumental in propagating those diseases. Much of what the ancients regarded as the mystery of infection, and attributed vaguely to the epidemic constitution of the air, or to obscure telluric conditions, if not to the interventions of providence, was shown to be due to a process of inoculation by some of the minute members of the insect family. It was said proverbially that the law cared not about minimal things. It had been reserved for the medical man and the pathologist to regard them, and to realise that—

"Great fleas have little fleas
Upon their backs to bite them,
And little fleas have lesser fleas,
And so *ad infinitum*."

Mr. Howlett had alluded to a case in India in which he had seen a remarkable collection of bugs *en masse*. He (the Chairman) would give an example nearer home. When he was attached to the resident staff of St. Bartholomew's Hospital some twenty-five years ago, and had to go into the purlieus of Cloth Fair and Central Street, St. Luke's, and thereabouts, he had seen quite as ample conglomerations of the active bug in some of the mean streets which, happily, had been largely swept away by the operations of the London County Council. As evidence of the difficulty of getting rid of the bug when once it had taken up its residence, he could recall when he was on the Housing Committee of the County Council, the extreme difficulty experienced in a certain doss-house not far from Drury Lane, in often getting rid of the bugs from the interior of the iron tubes of which the bedsteads were made. Apparently nothing short of actually exposing the iron to a high temperature was successful in getting rid of them. He was sure the members were greatly indebted to the learned author, whose absence they so greatly deplored, and also to Mr. Howlett, for having devoted so much of their lives to such an interesting, but, perhaps, in the minds of some people, such a repulsive topic. They had made themselves the familiar and the associate of the creeping and crawling things. They had not hesitated to make experiments *in corpore vili*. The public rejoiced in their results and discoveries, and could not help tendering to them their gratitude for the self-sacrifice which they had imposed upon themselves. It might be said of them that, like Prometheus, they had stolen the sacred fire from Heaven, and with it had illumined and animated the very dust, the filth, and the vermin of the earth.

Mr. G. Hurlstone Hardy suggested that the paper should be followed by another one dealing with the question of the cure for the complaints for which the insects were responsible. Dr. Ross's paper read before the Society last year was confined entirely to the fly, and it was followed by some most interesting correspondence. He began to study the subject of flies more than fifty years ago, and knew from his experience that a great deal of misunderstanding existed about them. He had been struck very forcibly, in listening to the paper, with the tenderness and delicacy of the body-louse, how readily it died, and yet it multiplied in enormous numbers. The same remark applied to the house fly. It was an artificial product which differed entirely from all the three thousand British flies, nearly one hundred of which were commonly mistaken for house flies, in that it sought the abode of man. It possessed peculiar habits, and it was only when they were fully understood and realised that a cure would be obtained. Little palliatives like fly-traps and very ineffective poisons were useless. After studying all the American reports he had come to the conclusion that much of the advice given was very often radically wrong; it was well intended, but was not correct entomologically. But there were great hopes, which rested largely upon the peculiar, delicate nature of the fly, which he suggested would form a good subject for a special paper. He had come to the conclusion that the cure for flies lay in the cremation of domestic rubbish.

Lieutenant K. B. Williamson said that he personally, and many others who were going to the scene of operations, would be only too glad if any details could be given by the author of the

newer method of dealing with the fly plague which he understood had been recently produced both at Cambridge and by Professor Lefroy, who recently lectured on the subject before the Zoological Society. He believed it was in the form of a spray, and it was said to be remarkably effective on the adult insect. He also heard, when he was at Cambridge, although he could not obtain any details, that another specific had recently been introduced by Dr. Graham Smith in collaboration with Dr. Warburton.

Mr. F. M. Howlett, in reply, said that he was entirely at one with the remarks that had been made by the first speaker. The delicacy of the adjustments, not only of lice but of house flies, to special conditions was a subject which it was impossible to avoid introducing if any work on it was done at all. At the same time, he did not think at present their knowledge was sufficiently deep. A good deal was known about the conditions in a superficial way, but enough was not known about their deeper physiology to enable them to say that they must adopt methods based on the adaptation of conditions against the fly rather than crude common-sense everyday methods such as sprays and the like. He had personally a great bias towards the adoption of anti-insect methods generally which were based upon a knowledge of their dependence upon particular conditions. A method had now been adopted which was based on a recommendation of his own for dealing with house flies by paying attention to one particular point in their life history, namely, that, when the house-fly maggot wished to turn to a pupa, to a chrysalis, it had to rid its body, somehow or other, of a certain amount of water to enable it to dry up sufficiently to form a proper pupa case. If it was living in a damp place, such as a manure heap, as it generally was, when it wanted to pupate it went outside the manure heap, or into its driest portions, before it did so. That method, which it was claimed had had good results in America, and had also been adopted at the front to a certain extent, simply consisted in keeping the manure damp, but arranging that within easy reach there should be dry places into which the maggots could go when they wanted to pupate, and which were so arranged that they could easily be destroyed by fire or otherwise when they got there. As to the cremation of domestic rubbish being the cure for fly-infestation, he thought the best thing he could do was to offer an invitation to Mr. Hardy to attend one of the lectures which he periodically gave to the London Sanitary Corps, in which he went as thoroughly as he could, in the course of an hour, into the actual practical methods adopted at the front and recommended at home for dealing with flies. The incineration of rubbish of all kinds was at present carried out wherever possible at the front, but the difficulty existed that that could not very often be done, either because there was no incinerator, or because such vast quantities of manure were being dealt with that it was beyond the capacity of the incinerators to cope with them. There was no doubt at all that it was an absolutely first-class thing to do. He also touched on, in the lecture to which he referred, the newer methods mentioned by Lieutenant Williamson. He recently went to Cambridge to see Dr. Graham Smith on the subject, and that gentleman appeared to have discovered something which was very good indeed as a deterrent to blow-flies—not house flies particularly—and as a general antiseptic of extraordinary power. He was shown a piece of a dead horse which had been left out in a field either for a fortnight or three weeks; it was not the least bad, and apparently no fly would lay any eggs on a piece of flesh that was treated with the stuff. He was not at liberty to say what the stuff was, but he would be only too glad to give any further details if possible. He (Mr. Howlett) could claim to be the inventor of the spraying method, and naturally he thought it was very good. The object kept in view was to make a spray which would clear hospitals and places of that sort, and it was found that by taking ordinary pyrethrum and treating it with alcohol a solution was obtained which, if it touched a fly, would paralyse it for some hours, but would not kill it. Within five minutes of spraying the flies fell down all over the room in a most gratifying way, but it was necessary to go round with a brush and sweep them up if it was desired thoroughly to clear them out. Ultimately he discovered a substance to add to the solution which not only completely paralysed them but killed them. He was afraid he could not tell the members what it was, but he could tell them where to get it; and he believed it was now being used at the front. He gave periodically a lecture to batches of about fifty men of the London Sanitary Corps before they went to the front. It was of a purely practical nature; it did not deal with scientific entomology or anything of that sort, but it answered the requirements which the speaker indicated. If any of the members cared to attend the lecture, and would furnish the Secretary of the Society with their names, they would receive a notification when the next lecture would be delivered.

On the motion of the Chairman a very hearty vote of thanks was accorded to the Master of Christ's College for his able lecture, and to Mr. Howlett for his admirable exposition thereof, and the meeting terminated.

GLASS IN INDIA.

The Quinquennial Review of the Mineral Production of India contains some information as to the occurrence of glass-making materials, which is of special interest in view of the efforts now being made to encourage the manufacture of glass in India.

There is no difficulty in obtaining the material for the inferior varieties of glass used for bangles, etc., as the common impure sands of the rivers and the efflorescent alkali salt abound in many parts of India. The chief obstacle to the manufacture of the better grades of glass is the absence of known deposits of quartz-sand of the requisite purity and of suitable texture. In a few places, however, attempts are being made to introduce European methods, and to make a better class of article. The factory at Rajpur, near Dehra Dun, known as the Himalaya Glassworks, which started in 1903, and seemed at one time on the road to success, has been closed down. In an interesting Blue-book published this year, Mr. F. O. Oertel describes a visit to glassworks in England, Austria, and Germany, analyses the causes of failure at Rajpur, and advances suggestions for the guidance of future enterprises of a similar nature. He especially advocates the manufacture of *churi*, or bangle glass.

No less than three other glassworks have been started under Indian management—viz., the Paisa Fund Glassworks at Talegaon, Poona district, Bombay, in 1908; the Upper India Glassworks at Ambala in 1914; and the Jubbulpore Glass Factory. The sand for the Talegaon works is obtained by crushing quartz found locally, and the lime is obtained from Bombay. The sand and lime for the Ambala works are obtained from Dehra Dun; for the Jubbulpore works the sand is local, and the lime obtained from Katni. The soda is imported in each case. These factories devote themselves principally to the manufacture of lamp globes and chimneys, bottles and tumblers; but other articles are also produced, especially at Talegaon.

The sands found at various localities in the Rajmahal Hills, and reported to be suitable for glass-making, have been investigated by Mr. Murray Stuart. He considers that they are generally unsuitable for the manufacture of any but the commonest kinds of bottles. The sands considered occur as (1) recent river-sands, and (2) Damuda (Gondwana) sandstone.

To what extent a glass-making industry would find a market in India may be judged by the fact that during the past fifteen years the annual imports of glass and glassware have gradually risen in value from £440,000 to over £1,300,000 in 1913, the average value for the period being £1,057,788. The chief items in this total are bangles, beads, and false pearls, common bottles, lampware, sheet and plate glass.

THE REELING OF TUSSAR SILK.

Tussar silk is more difficult to reel from the cocoons than mulberry silk, and the cocoons must be boiled in an alkaline liquid preparatory to this operation. The natives add the ashes of plantain leaves to water and boil the cocoons in this for two or three hours, and then leave them to ferment for some hours before winding. In some factories in Bengal the cocoons with their stems cut off are tied up loosely in a cloth; this is weighted down with stones and boiled for half an hour in a solution containing three parts of potassium carbonate dissolved in eighty parts of water, oil and sugar being sometimes added. The cocoons are afterwards boiled for a few minutes in water containing a little glycerine. The silk is then reeled in the same way as mulberry silk. The glycerine keeps the cocoons moist while reeling, and it is not then necessary to keep them in basins of water during this operation. Another method is to prepare a fine powder or paste from the chrysalides of tussar or mulberry insects; about one part by weight of this is mixed with two parts by weight of dry cocoons and the mixture is tied up in a cloth, weighted, and immersed in water, which is then boiled for an hour. The mixture is next left to ferment for twelve hours, after which reeling begins, the cocoons being allowed to rotate in basins of hot water just as when mulberry cocoons are reeled.

The reeled silk obtained by any of the above processes must next be immersed in a warm acid solution, then washed in a bath of boiling soap or washing soda solution, and finally rinsed in boiling water, wrung, dried, and baled for export. The object of the acid bath is to neutralise the lime and alkali, which would lessen the brilliancy and elasticity of the fibre; it can be prepared from tamarinds, using one part by weight of tamarinds in water to every four parts by weight of tussar thread. The tamarinds are washed and mixed with water, and the liquid is strained through a cloth. The treatment with soap or washing soda can be omitted, but the final rinsing with boiling water must be done. One man can reel about 260 tussar cocoons in a day, obtaining 18 to 20 tolas (about half a pound) of silk.

It is stated that one difficulty in reeling tussar silk is to make the separate strands cohere in the reeled thread; in the case of mulberry silk the cement is only softened in the reeling basin, and hardens again, gluing the strands together.—*Bulletin of the Imperial Institute.*

DEVICE FOR COMPUTING VALUES OF TUNGSTEN LAMPS.

It is well known that a change in the voltage applied to the terminals of an incandescent lamp changes the candle-power, current, and, in consequence, the wattage (watts = volts × amperes) and the watts per candle. If these changes are followed from point to point, relations among the variables may be found and plotted as characteristic curves. The equations of these characteristic curves for tungsten lamps have been found by the Bureau of Standards of the United States Department of Commerce, and a special application of these equations has been made in a device which gives a

solution of problems involving voltage, candle-power, and watts per candle.

In this device the volt scale is movable, and, by setting it to the other scales at a point corresponding to the observed watts per candle, values of per cent. candle-power and of actual watts per candle may be read directly from the proper scales, or the converse problems may be solved. Use of this device results in a decided saving of time when compared with other methods of characteristic evaluation. In connection with the device are given tables of values used in its construction and practical examples illustrating scale settings.

Copies of the report upon this subject may be obtained upon application to the Bureau of Standards, Washington, D.C.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Indispensable Men.—It has been announced that the official List D, consisting of men engaged in occupations of cardinal importance and "starred" for recruiting purposes, is open to subsequent revision. In order to meet the ideas of textile employers the revision must needs be extensive. The list omits the names of many callings which have the same right to inclusion as any that appear, and it takes no account of others whose position is incontestably more critical. It is inconsistent at least to forget the linen and jute trade entirely, while remembering the cotton, woollen, worsted, and silk industries. Then a list is manifestly incomplete which provides for the case of the workman but not for that of his manager. These major inconsistencies leap to the eyes, and on a closer examination the selection of grades of workpeople is seen to bristle with smaller ones. Manufacturers would be left with warps apparently, and with female weavers, but without men for warp-dressing and twisting-in, and without foremen dyers to dye the goods when made. There seems to be more to hope from a consideration of individual cases upon their merits, than from any attempt to lay down unyielding rules.

Curious Trade-names.—Trade names offer a rich quarry to the lover of the curious, and every long list of them brings unfamiliar names to light. The schedule of starred trades presents a few, including that of the "taper" in the cotton mill. The slightly derogatory flavour attaching to such a name is imperceptible in Lancashire, where a taper is a man of consequence. He has no connection with cotton tape of the ordinary variety, although a tape-like appearance is assumed by the parallel warp-threads that it is his business to treat. A taper is a sizer whose machine applies mucilaginous matter to the warp to facilitate its weaving. The sizing must neither be too strong nor too weak if the weaver is to be spared fruitless trouble, and in this matter experience is the great guide. The machine at which he works is normally of the type called "slasher," and for greater security the official list names sizers thrice, first as sizers, second as slashers, and third as tapers. The "openers" of the cotton trade are in charge of the opening machines for cleaning and disentangling matted fibre, and the "scutchers" have a not dissimilar duty. The "overlooker" whose business lies with machines and operatives, is a functionary distinct from the "lookers-over" who practise a cultivated rapidity in noticing anything that is amiss with woven cloth. A "tackler" is a weaving overlooker and is the Lancashire equivalent of the Yorkshire "tuner." The "grinder" in a preparing or spinning mill, grinds to uniform length the wire teeth of the rollers and cylinders of the carding machines. "Fettlers" in the woollen trade perform other work in making ready the carding-engines, and when a fettler works in the worsted trade his name is "jobber." Among quaintly-named trades not mentioned in the list in point may be included the "slubber," who is concerned with light, loose, barely-twisted ropes of prepared fibre, and the "crabber," who crabs the shrinking and cockling tendencies inherent in undyed worsted cloth. The dyehouse has its "box-watchers," who have the function of watching patent dyeing machines, and its "top-siders" and "low-siders," who share between them an unequal responsibility for the due guiding and working of the cloth.

Sample Exhibition.—Manufacturers in various parts of the country have refreshed their acquaintance with German goods by examination of the samples exhibited successively in different centres by the Board of Trade. Any one manufacturer is directly interested in what is only a very small part of most of these aggregations of mixed samples, and the picking-up of valuable ideas, other than general ones, must remain much a matter of chance. It appears that some visitors have discovered suggestive trifles, and have carried away ideas to be elaborated later. In the ordinary way, the practical man is more interested in an idea to turn to immediate account than in revolutionary methods, and he is not ungrateful for inspiration wherever found. A small cutting of cloth, embodying some feature which can be expanded without being actually imitated, is valued, although perhaps for reasons distantly removed from the capture of any specifically German branch of trade. In that manner a wholly fortuitous collection of miscellanies may be capable of use, and such sample exhibitions as have been seen hitherto have worn the unmistakable air of chance, not of orderly selection and rejection.

Some German Goods.—The uninstructed public wandering through the exhibition rooms displays an indiscriminate awe and wonder at "what we have to beat," with never a suspicion that the exhibits include goods in which the Englishman has the German beaten handsomely from the beginning. It can be said with some emphasis

that there are no livings to be made in England by producing such woollens and worsteds as were displayed in the recent exhibition at Leeds. The goods were of altogether undistinguished style, and with few exceptions represented lamentable value for money. So far from being examples to emulate they were gratuitous instances of what to avoid, and they were not the only types of which it could be predicated, with entire conviction, that not much could be sold. The presence of such goods cheek-by-jowl with some more deserving of attention is not all to the advantage of these exhibitions, and in this matter there is room for discrimination. Presumably in time to come greater effort will be exerted to make the home market, at any rate, more self-supporting in the supply of wool plushes for slippers and upholstery. The yarns and looms used being mainly English, it would not seem out of the question to weave them here, and also to produce such waste-cotton tapestries as are employed as cheap cushion-squares. Some wool cashmere dress-stuff patterns, all the way from Fiji, are rather of French than English interest, as France is in possession of the requisite types of machinery. An effective reason why the production of certain calico prints and other coloured goods will not be attempted at present in England lies in the absence of dyestuffs.

Clothes and the Sun.—A report upon sanitation in India has been briefly quoted in the English press, relating that there is no foundation for the belief that a red lining to helmets reduces the temperature of the air between helmet and scalp. It may be doubted, however, whether reduction of temperature is the objective of the helmet maker, any more than it is of the khaki-drill manufacturer who reddens his fabrics on the obverse. Drills are sometimes dyed red upon one side only by means of the pad-dyeing machine, or are woven with a red weft which is concealed upon the face by the brown threads of the warp. In either event, the theory is that the red lining acting as a light-filter, cuts off the actinic rays of the sun in the same way as the red glass in the photographic dark-room light. The actinic rays in turn are understood to be those most provocative of prickly discomforts to the skin. Red is not credited with great virtues of heat-absorbency, and if it were the place for it would plainly be the surface upon which the rays strike. The outside of the helmet or garment might be red-coloured, were it seriously supposed that a red surface afforded more protection than the obviously cooler yellow, or the still cooler white.

Japanese Competition.—Reports tell of a new activity in Japanese competition in the cotton trade. Both in Bombay and in Manchester patterns have been shown of finer makes than have come from Japan hitherto, and in India a considerable amount of business has been booked. Skill has been shown in duplicating standard Bombay drills and satins, and Lancashire shirtings and dhootie cloths. Some of the prices named give the Japanese offer an appearance of extraordinary cheapness. Except in cases of desperate need established makes could hardly be quoted so much below the market, and the inference is that the producers are uncommonly eager to break into the new fields. Generally, Japanese textile workmanship is found less thorough and consistent than English, and the effect is of course to make the goods worth less in the eyes of the buyer than those which can be relied on implicitly. Time must be left to pronounce upon the quality of Japanese deliveries, but the forward step in attempting these more advanced articles cannot be ignored. Some circumstances of freight and exchange are exceptionally favourable to Japan at the present, and doubtless the most is being made of these.

The Boom in Hosiery.—The British hosiery industry will come out of the war a much larger one than in 1914. Extension goes on in apparently all the towns and villages in which hosiery is manufactured, and the development is perhaps nothing to wonder at. The great source of imported knitted goods has been cut off, and at the same time the consumption of knitted garments has been enormously increased by the two winter campaigns. To an astonishing extent the demand has been for goods of a high quality, and the consumption of the hosiery trade has great responsibility for the present price of wool. The present prosperity does not quell doubts of what is to happen later when the military demand ceases and the civilian consumers begin to look afresh for cheap undergarments at the prices hitherto paid for the mock woollen clothing imported from Germany. Certainly a great number of people must now be wearing wool where they formerly wore cotton-waste, garnished with labels declaring it "Natural" and "Unshrinkable"—echoes of the descriptive epithets applied to wool. Having made one change they are hardly likely to go back to precisely the same kind of goods as before, and henceforth British manufacturers with their enlarged plants will be less inclined to allow the Saxon and the Wurtemberger to take the business. The time has not come as yet, however, to discuss the making of cheaper stuff. Meantime, the shop windows and the lists of apparel supplied to the army are eloquent of the development of the knitting trade.

OBITUARY.

Sir Michael Barker Nairn, Bt.—Sir Michael Barker Nairn, of Rankeilour, who had been a member of the Royal Society of Arts since 1866, died from heart failure while motoring to his office at Kirkcaldy on November 24th. He was born in 1838, the eldest son of Mr. Michael Nairn, founder of the floorcloth industry in Scotland, and was

chairman of Michael Nairn & Co., Ltd., linoleum manufacturers, of Kirkcaldy, with branches in France, America, and elsewhere. In 1900 he contested Kirkcaldy Burghs unsuccessfully in the Unionist interest. He took a deep interest in education. For many years he was chairman of the Kirkcaldy School Board; he presented a high school and a hospital to his native town, and endowed some bursaries for university students. He was created a baronet in 1904.

MATTHEW HAMILTON GRAY. — Mr. Matthew Hamilton Gray died on September 2nd. He, like his father and three of his brothers, was a life member of the Society, which he joined in 1898. His elder brother Robert, who was a member of nearly ten years longer standing, took a very active part in the work of the Society, but Mr. Matthew Gray never associated himself very prominently in the proceedings of the societies with which he was connected, though, like his brother, he was greatly liked by a large circle of friends, and was also, like him, constantly active in good works of a private nature.

He was born in 1854 at Glasgow, and started in life as a mining engineer. After a few years' experience in America, Borneo, and China, he joined his father and his elder brothers in the service of the India-rubber, Gutta-percha, and Telegraph Works Company of Silvertown. His work with the company was all, or nearly all, connected with cable-laying; and he acted as engineer-in-charge of most of the cable-laying operations of the company.

NOTES ON BOOKS.

THOMAS GAINSBOROUGH. By William T. Whitley. London: Smith, Elder & Co. 1915.

When the Society of Arts was founded in 1754 Gainsborough was already established as an artist, and was working at Sudbury in Suffolk. His student days were therefore over, and he was unable to profit by the encouragement given to many who were almost his contemporaries by the Society's Prizes. He studied in London for about five years, having been sent up by his father when he was thirteen years old, about the year 1740. Part of his art education he may have obtained at the St. Martin's Lane Academy, which was founded by Hogarth some six years before Gainsborough's arrival in London. That this was the case has been stated by some of his previous biographers, but Mr. Whitley thinks that he never was at the academy, because his name does not appear in a list of old students given by W. H. Pyne in his curious publication, "Wine and Walnuts."

Pyne says that he was assisted in the preparation of this list by John Taylor the artist. Now Mr. Whitley argues that as Taylor knew Gainsborough well, and as Pyne was a great admirer of his, and collected a great deal of gossip about him, it is unlikely that they should both have forgotten so important a name. But the list must have been compiled a long time after Gainsborough was dead and when Taylor was a very old man, and lists compiled under these circumstances are not likely to be very complete. The matter, therefore, must be left in obscurity.

Nor was Gainsborough one of the artists who contributed to the first of all picture exhibitions held in London, which was organised by the Society of Arts in 1760, though he did send a picture to the 1761 exhibition which was held in Spring Gardens by the Society of Artists of Great Britain. This second exhibition was, to a large extent, carried out by Francis Hayman, at whose suggestion it was that the Society had held an exhibition in the previous year at its house opposite Beaufort Buildings. It was under Hayman that Gainsborough had studied while in London, and it was at Hayman's suggestion that he contributed to the Spring Gardens exhibition.

The only connection which Gainsborough had with the Society was when he painted the picture of Viscount Folkestone, the Society's first president, for the Society. A full account of the circumstances connected with the painting of this picture is given by Mr. Whitley. The Society was anxious to obtain a companion portrait for the one of Lord Romney, its second president, which had been painted by Sir Joshua Reynolds, and as at the time (1774) Lord Folkestone was dead, an application was made to his son, who had become the Earl of Radnor, asking him to lend the three-quarter length portrait of his father which Hudson had painted in 1749, in order that from it a portrait might be made for the Society. Lord Radnor having consented, it was necessary to find an artist, and at first arrangements were made with Nathaniel Dance to paint an enlarged and altered version of Hudson's work—"a whole-length portrait drawn in the proper Coronation robes, and the same size as the portrait of Lord Romney." For some reason or other, illness and pressure of work being made the excuse, Dance never even began the work, and finally declined. As Mr. Whitley remarks, he throughout appears to have treated the Society with discourtesy. At all events, however this may be, the old minutes show that he seems to have been rather careless in the way he treated the commission, and to have been the cause of not a little trouble and annoyance.

However, the matter was promptly and more satisfactorily settled by Gainsborough's ready assent to a suggestion which came from Lord Radnor himself, that he should be employed for the purpose, and the result was that the Society possesses a portrait of far more interest and value than anything which Dance could have produced. Gainsborough did the work in the most satisfactory manner, and the Society showed its appreciation not only by telling him that they were highly satisfied with his masterly performance, but by the liberal manner in which they dealt with the matter of payment, for it was not

until after the picture had been finished that the artist was asked to mention the remuneration which he expected. Gainsborough then said that his usual fee for a work of this sort was 100 guineas, and this, which was double the sum Dance was to have received, was paid without demur.

There have been so many lives or accounts of Gainsborough that it might have been thought there was hardly room for another. But Mr. Whitley, by his diligent and painstaking research, has added a good deal to our knowledge of the artist, and in many minute details has corrected statements of his predecessors. Much of his new information is derived from the numerous references to Gainsborough by his friend the Rev. Henry Bate, afterwards Sir Henry Bate Dudley, well known as the "fighting parson," one of the founders of the *Morning Post*, and afterwards proprietor of the *Morning Herald*. Mr. Bate, as he was at the time, was a fervent admirer of the painter, and "in the *Morning Herald* he chronicled the progress of Gainsborough's pictures, and supported him against the Academy and against everyone who dare to question his artistic supremacy."

Dudley received two prizes from the Society—a Silver Medal in 1787, and a Gold Medal in 1801—for reclaiming land from the sea. The land was part of the glebe belonging to the parish of Bradwell in Essex, the advowson of which he had purchased. When he abandoned journalism to resume his clerical functions, he presented himself to the living, but was not allowed to occupy it, as he was accused of simony.

Another source upon which Mr. Whitley has drawn is provided by contemporary local newspapers. He has even gone so far as to study their advertisement pages, and from them he has managed to discover the precise dates, previously unknown, of many of Gainsborough's movements. For instance, while he has not been able to satisfy himself as to the exact house in The Circus at Bath inhabited by Gainsborough, he appears to have produced conclusive evidence that it is not the one numbered 24 upon which the Corporation of Bath some time ago erected a tablet. The Royal Society of Arts, mindful of the mistake about the Franklin Tablet in Craven Street, Strand, may sympathise with the Corporation, having had a like experience of the difficulty of precise identification of eighteenth-century dwellings.

Some interesting details are given about the house in Pall Mall, on which the Society placed a tablet to Gainsborough about 1883, though it does not appear that Mr. Whitley realises that further demolitions in Pall Mall have taken place since he wrote his account. Though the part of Schomberg House which formed Gainsborough's dwelling is still intact, what was originally the central portion, and was for long the War Office, was pulled down some years ago, and its site is at the present time occupied by the imposing building of the Automobile Club.

It may be worth mentioning that the exhibition to which, as Mr. Whitley says, Sandby contributed his picture of Lord Harcourt's house in 1760, was the parent exhibition of the Society of Arts, which was not one of the series held by the Society of Artists. The Society of Artists called their first independent exhibition in 1761 the second exhibition, and this it certainly was in a sense, but it was not the second held by the artists themselves.

METALS AND METAL-WORKING IN OLD JAPAN. By Professor William Gowland, A.R.S.M., F.R.S., F.I.C., F.S.A.

The paper which Professor Gowland read before the Japan Society last March has now been reprinted in pamphlet form. Running as it does to nearly one hundred pages, it forms perhaps the most valuable contribution to the subject that has yet been published. The author possesses a fourfold qualification for this task: he is not only one of our first metallurgists; he is also a devoted archæologist and a lover of art, and he spent some sixteen years in Japan as chemist, assayer, and foreign head of the Imperial Japanese Mint.

The pamphlet includes most of the material of the valuable paper on "The Art of Casting Bronze in Japan," which was read by the author before the Applied Art Section of the Society in 1895; but, of course, it covers a great deal more ground, for it treats of all the principal metals over a period of upwards of 2,000 years. It starts with the bronze age, which dates back to some seven or eight centuries before the Christian era, when the Japanese appear to have migrated from the continent of Asia to the islands they now occupy. The aborigines apparently had no knowledge of the use of metals. The earliest examples of Japanese metalwork are two-edged bronze weapons, and Professor Gowland's first illustration is of a stone mould for casting bronze halberds.

A very interesting account, with a curious illustration, is given of the early Japanese method of extracting gold. The metal was obtained by a series of simple washing processes, which seem to have been conducted with much skill. "At the present day some is still similarly obtained, and often from sands containing such small quantities that the Western processes fail to compete successfully with the primitive methods of the Japanese gold-washers.

"The old gold-washers seemed to have received no wages: sufficient gold dust adhered to their garments; and it is naïvely added that sometimes even a nugget became accidentally attached, and this was sufficient to recompense them for their labours."

A special word of praise must be given to the illustrations, which have been selected and reproduced with great care. Particularly interesting is Figure 11, which represents Chinese smiths forging an anchor, and shows how heavy operations were conducted when cranes and similar mechanical appliances were unknown; and particularly beautiful is the figure facing it of the wrought-iron eagle, the original of which is to be seen in the Victoria and Albert Museum.

GENERAL NOTES.

TRADE OF PORT OF NEW YORK AND THE WAR IN EUROPE.—A French journal gives the following figures, showing in francs the value of the exports from the port of New York during the first thirteen months of war, as compared with those of similar period of the previous year:—

	Aug. 1st, 1914, to Sept. 30th, 1915. Francs.	Aug. 1st, 1913, to Sept. 30th, 1914. Francs.
England . . .	2,020,401,555	1,054,564,600
Belgium . . .	3,673,700	146,216,155
France . . .	1,265,291,040	357,521,385
Italy	420,612,580	172,367,270
Russia . . .	180,942,180	109,469,260
Germany . .	29,010,340	453,600,745
Austria-Hungary	177,345	75,349,520
Denmark . .	225,611,070	33,654,070
Spain	30,414,895	38,859,335
Greece . . .	85,671,800	51,830,580
Holland . . .	405,045,610	343,116,045
Norway	110,869,440	34,704,010
Sweden . . .	184,983,600	31,971,200
	4,962,705,185	2,897,224,175

This shows an increase in the value of the shipment of 2,065,481,010 francs during the war.

BOOKS FOR BRITISH PRISONERS AT RUHLEBEN.—The Board of Education have issued a further appeal for books of an educational character for the British civilian prisoners of war (of whom there are some 4,000) now interned at Ruhleben, in Germany. Under the auspices of a Camp Education Department a school and a science and art union have been organised among the prisoners, and in them are enrolled 1,500 students, with 150 lecturers and teachers. The educational work is divided into nine sections, and covers languages, art, science—in fact, nearly all the usual subjects of a school or college curriculum. Persons willing to contribute either books or money may obtain a circular, giving full information on the subject, by addressing a post-card to Mr. Alfred T. Davies, Board of Education, Whitehall, S.W., who is in charge of the arrangements for obtaining and forwarding the books to Ruhleben.

INDUSTRIES IN WEST CHINA.—According to a recent official report, the district of Tzeliuching, which lies in the south-central part of Szechuan, some fifty miles north of Suifu, is the most important industrial centre in West China. This is true not only as regards its present state of development, but also as regards its potentialities and possibilities. Tzeliuching at no distant date will place larger orders for foreign machinery than any other city in this part of China. Machines for drilling new wells, for pumping up the brine, and for evaporating the salt are of first importance. Simple hoisting engines to supplant the water buffaloes should enjoy a large sale. Gas stoves and burners and engines using gas for fuel could also be introduced. As the salt wells are operated night and day, there is an excellent opportunity for the sale of electric-lighting plants. Telephone apparatus is also in demand, and mine pumps and machinery are needed in the coal-fields. There is almost no limit, in fact, to the potential demand; there are, however, many obstacles in the way of meeting it. The vested interests of both labour and capital make it hard to introduce new methods here; a sudden change in this regard would throw hundreds of thousands out of employment. The importance of having a personal representative on the ground cannot be too strongly emphasised. It is utterly impossible to obtain the enormous business at Tzeliuching merely by means of letters and catalogues. An agency placed with some company that carries competing lines is of very little value.—*London and China Telegraph.*

PRACTICAL INSTRUCTION TO MUNITION WORKERS AT MILAN.—A special course of instruction for turners engaged in the manufacture of munitions has been lately opened at one of the principal industrial schools at Milan (Istituto industriale Giacomo Feltrinelli). This institute was established some years ago for the practical and theoretical instruction of mechanics and workers engaged in the metal trades, and for the purpose of encouraging national industry. The number of pupils is limited to the number of lathes at the disposal of the institute. It is, however, a step in the right direction.

KAPOK OIL USED FOR INDUSTRIAL PURPOSES.—Kapok oil is used in the district around Marseilles exclusively for industrial purposes, chiefly soap-making. The residue, or oil-cake, is employed as a fertiliser. The quantity of kapok seed imported into Marseilles cannot be ascertained from the customs statistics, as this product is not separately classified; but according to local brokers it averaged during the last five years about 1,500 metric tons. India is the principal country of origin. The seed is treated in two mills, both of which are, however, chiefly devoted to the crushing of other seeds. According to a report by the United States Consul-General at Marseilles, the seed goes through the same process as cotton-seed and peanuts. Only one pressing is the rule, although in some cases hot water is poured over the residue, which is then pressed again. The oil is then filtered, but it requires neither bleaching, deodorising, nor any other treatment. In the Marseilles mills the average yield in oil from this seed is about 15 per cent. On June 5th last the ruling prices were 70 to 75 francs per 100 kilogrammes (28*s.* 6*d.* to 30*s.* 6*d.* per cwt. about) for oil, and 7 francs per 100 kilogrammes (2*s.* 10*d.* per cwt.) for cake, but the latter is an abnormally low price, resulting from the French Government's embargo on oil-cake shipments. The price of the oil follows closely that of industrial peanut oil. It

takes about 16½ lb. of kapok oil to make a gallon. The density of the oil is 0·9237 at 15° C.; in other words, it is about the same as cotton oil.

THE TRADE OF ASSAM.—According to a report on the trade between Assam and the adjoining foreign tribes and countries, the value of imports during the year 1914-15 was Rs. 19,63,396 against Rs. 18,72,865 in the previous year, the increase being Rs. 90,531, or 4·8 per cent. The increase occurred chiefly under the head of animals, dyeing materials, hides and skins, musk, spices, and blankets. The total exports amounted to Rs. 16,46,659, representing an increase of Rs. 31,710, the greater part of which occurred under metals, silk, and betelnut. About 96 per cent. of the total trans-frontier trade is carried on with Bhutan, and the value of the import trade with this country rose by Rs. 89,040. The offer of higher prices for ponies, and the larger demand for horned cattle in the previous year, apparently stimulated the Bhutias to visit the plains in larger numbers. The principal articles of imports were ponies (Rs. 1,11,033), horned cattle (Rs. 43,932), oranges, hides and skins, lac, musk, ghee, spices, wax, and woollen goods.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.

DECEMBER 8.—LIEUT.-COLONEL W. A. TILNEY, F.R.G.S., F.R.A.S., late 17th Lancers, "The Art of Finding your Way at Night without a Compass." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, will preside.

DECEMBER 15.—J. JEF. DENYN, Carillonneur de Malines, and WILLIAM W. STARMER, F.R.A.M., "Carillons and Carillon Playing." W. G. MCNAUGHT, Mus.Doc., will preside.

INDIAN SECTION.

Thursday afternoon, at 4.30 p.m.:—

DECEMBER 16.—C. C. MCLEOD, President of the London Jute Association, "The Indian Jute Industry." SIR JOHN PRESCOTT HEWETT, G.C.S.I., C.I.E., will preside.

Papers to be read after Christmas:—

PROFESSOR J. A. FLEMING, M.A., D.Sc., F.R.S., "The Organisation of Scientific Research." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, will preside.

R. W. SETON-WATSON, D.Litt., "The Balkan Problem."

CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Optical Appliances in Warfare."

LAWRENCE CHUBB, "The Common Lands of London: the Story of their Preservation."

THE HON. LADY PARSONS, "Women's Work during and after the War."

REV. P. H. DITCHFIELD, "The England of Shakespeare."

W. A. CRAIGIE, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

VICTOR HORTA, Directeur de l'Académie Royale des Beaux-Arts de la Ville de Bruxelles, "Belgian Architecture."

CHARLES DELCHEVALERIE, "Belgian Literature."

LESLIE URQUHART, "The Economic Development of Russia."

J. ARTHUR HUTTON, Chairman of the British Cotton Growing Association, "The Effect of the War on Cotton Growing in the British Empire."

S. CHARLES PHILLIPS, M.S.C.I., "Paper Supplies as affected by the War."

PROFESSOR T. G. MASARYK, "The Slavonic Peoples."

COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., late Survey of India, "The Romance of the Indian Ordnance Survey."

C. A. KINCAID, C.V.O., Indian Civil Service, "The Saints of Pandharpur."

SIR DANIEL MORRIS, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland."

PROFESSOR WYNDHAM R. DUNSTAN, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India."

INDIAN SECTION.

Thursday afternoons at 4.30 p.m.:—

January 13, February 17, March 16, April 6, May 18.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

February 1, March 7, May 2.

CANTOR LECTURES.

Monday afternoons at 4.30 p.m.:—

WALTER ROSENHAIN, D.Sc., F.R.S., Superintendent, Metallurgy Department, National Physical Laboratory, "Optical Glass." Three Lectures.

Syllabus.

LECTURE II.—DECEMBER 6.—History of optical glass manufacture—Fraunhofer, Guinand, Feil, Bontemps, Chance—Schott and Abbe—Hopkinson and Stokes—Efforts in England. The present method of optical glass manufacture—The furnace—The pot—Production and treatment—The process of melting and fining—Stirring and finishing—Cooling—Breaking up, selecting and moulding—Annealing—The final form of the glass.

LECTURE III.—DECEMBER 13.—The presen process of manufacture—General difficulties—Costliness—Cost of the pot—Time of production—Cost of melting—Raw materials—Low yield of good glass—Risks of the process—Risks of loss during melting—Failures due to striæ—Risks of contamination—Errors and variations of optical constants—Range of glasses demanded by opticians—Small quantities required—Need for large stock of optical glass. Special difficulties in England—Cost of raw materials and of labour—Refractories. Special difficulties connected with "new" glasses—Their chemical activity—Action on pots—Absorption of colouring impurities—Attainment of extreme optical properties. Need for research—The general problem—How to make good optical glass—Necessary improvements in pots and refractories, and in furnaces and methods of working—Utilisation of new materials and electric methods—The special problems relating to individual types of glasses—Optical and other properties to be realised simultaneously—The limitations of possible glasses—Optical properties of crystalline media—Future possibilities.

J. ERSKINE-MURRAY, D.Sc., F.R.S.E., M.I.E.E., "Vibrations, Waves, and Resonance." Four Lectures.

May 1, 8, 15, 22.

FOTHERGILL LECTURES.

Monday afternoons, at 4.30 p.m.:—

REV. DR. HERBERT WEST, D.D., A.R.I.B.A. (author of "Gothic Architecture in England and France"), "Flemish Architecture." Three Lectures.

February 7, 14, 21.

EDWARD A. REEVES, F.R.A.S., Map Curator, Royal Geographical Society, "Surveying." Three Lectures.

March 27, April 3, 10.

JUVENILE LECTURES.

These Lectures will be given on Wednesday afternoons, January 5 and 12, at 3 p.m. The first lecture will be given by Professor John Millar Thomson, LL.D., F.R.S., on "Crystallisation," and the second by Mr. James Swinburne, F.R.S., on "Science of some Toys."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DECEMBER 6...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cantor Lecture.) Dr. W. Rosenhain, "Optical Glass." (Lecture II.)

Farmers' Club, Whitehall Rooms, Whitehall-place, S.W., 6 p.m. Mr. C. Turnor, "Land Settlement in England as affected by the War."

Brewing, Institute of (London Section), Imperial Hotel, Russell-square, W.C., 8 p.m. Mr. E. C. de Peyer, "Brewery Accountancy and Income Tax."

Engineers, Society of, Caxton Hall, Westminster, S.W., 7.30 p.m. Mr. A. Steiger, "The Modern Development of Water Power."

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m. 1. Professor F. G. Donnan, "On the Use of Graphical Methods in the solution of Problems in Technical Chemistry." 2. Mr. T. C. Cloud, "The Transport of Material in the Form of Dust." 3. Mr. M. S. Salamon, "Sampling and Analysis of Beeswax."

TUESDAY, DECEMBER 7...Cold Storage and Ice Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 7.30 p.m.

Marine Engineers, Institute of, The Minories, Tower-hill, E., 7 p.m. Mr. A. J. Lebeda, "Stern Shaft Lubrication."

Photographic Society, 35, Russell-square, W.C., 8 p.m. Mr. W. T. P. Cunningham, "Intensification."

Röntgen Society, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8.15 p.m. 1. Mr. L. A. Levy, "Some Remarks on Fluorescent and Intensifying Screens." 2. Mr. G. G. Blake, "Further Notes on Localisation."

WEDNESDAY, DECEMBER 8...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Lieut.-Colonel W. A. Tilney, "The Art of Finding your Way at Night without a Compass."

Biblical Archæology, Society of, 37, Great Russell-street, W.C., 4.30 p.m. Dr. A. H. Gardiner, "The Foreign Script of Sinai."

Geological Society, Burlington House, W., 8 p.m.

Electrical Engineers, Institution of (Yorkshire Section), Philosophical Hall, Leeds, 7 p.m. Professor A. B. Field, "Some Difficulties of Design of High-speed Generators."

THURSDAY, DECEMBER 9...British Academy, in the Theatre, Burlington-gardens, W., 5.30 p.m. (Schweich Lectures.) Monsieur E. Naville, "The Text of the Old Testament." (Lecture I.)

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Child Study Society, at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W., 6 p.m. Dr. C. W. Kimmins, "Children's Interest in the War at Different Ages."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. A. C. Braham, "Autotype Printing, including the new White Carbon Tissue."

Optical Society, at the Chemical Society, Burlington House, W., 8 p.m. Mr. H. A. Hughes, "Improvements in Prismatic Compasses with special reference to the Creogh-Osborne patent Compass."

FRIDAY, DECEMBER 10...Malacological Society, at the Linnean Society, Burlington House, W., 7 p.m. 1. Dr. W. H. Dall, "Note on the Oligocene of Tampa, Florida, the Panama Canal Zone, and the Antillean Region." 2. Mr. G. K. Gude, "Description of two new species of *Angasella*."

Astronomical Society, Burlington House, 5 p.m.

Water Engineers, Institution of, at the Geological Society, Burlington House, W., 2.30 p.m. Mr. P. Griffith, "Notes on the definition of the term 'Domestic Purposes' in General and Private Acts."

Journal of the Royal Society of Arts.

No. 3,290. VOL. LXIV.

FRIDAY, DECEMBER 10, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 13th, at 4.30 p.m. (Cantor Lecture.) WALTER ROSENHAIN, D.Sc., F.R.S., Superintendent, Metallurgy Department, National Physical Laboratory, "Optical Glass." (Lecture III.)

WEDNESDAY, DECEMBER 15th, at 4.30 p.m. (Ordinary Meeting.) JOSEF DENYN, Carillonneur de Malines, and WILLIAM W. STARMER, F.R.A.M., "Carillons and Carillon Playing." W. G. MCNAUGHT, Mus.Doc., F.R.A.M., will preside.

THURSDAY, DECEMBER 16th, at 4.30 p.m. (Indian Section.) C. C. MCLEOD, President of the London Jute Association, "The Indian Jute Industry." SIR JOHN PRESCOTT HEWETT, G.C.S.I., C.I.E., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday afternoon, December 6th, DR. WALTER ROSENHAIN, F.R.S., delivered the second lecture of his course on "Optical Glass."

The lectures will be published in the *Journal* during the Christmas recess.

COLONIAL SECTION COMMITTEE.

A meeting of the Committee of the Colonial Section was held on Tuesday afternoon, the 7th inst. Present:—

Lord Blyth (Chairman of the Committee), Dugald Clerk, D.Sc., F.R.S. (Chairman of the Council), Byron Brenan, C.M.G., Richard Ernest Brounger, Hon. Sir John A. Cockburn, K.C.M.G., George Wilson, C.B., with Sir Henry Trueman Wood (Secretary of the Society), and S. Digby, C.I.E. (Secretary of the Section).

JUVENILE LECTURES.

Two of the Members of the Council—Professor John Millar Thomson, LL.D., F.R.S., and Mr. James Swinburne, F.R.S. — have kindly undertaken to deliver the Juvenile Lectures this year. Professor Thomson will give the first lecture on Wednesday afternoon, January 5th, at 3 p.m., his subject being "Crystallisation." Mr. James Swinburne will give the second on Wednesday, January 12th, at 3 p.m.; his subject will be "Science of some Toys." Both lectures will be very fully illustrated with experiments.

Special tickets are required for these lectures. They can be obtained, when ready, on application to the Secretary.

A sufficient number of tickets to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply for them at once.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

EXAMINATIONS, 1916.

ENGLISH FOR FOREIGNERS.

It has been determined to add to the subjects for the examinations for the present year the subject of English for French and Belgians This examination is intended specially for the benefit of Belgian refugees in England, but candidates of other nationalities can enter. The examination will be divided into two separate parts, Written and Oral. Candidates can enter for either part of the examination, or for both parts.

I. WRITTEN EXAMINATION.

The written examination will be held under precisely the same conditions as the other examinations of the Society. These are held (1) in April and (2) in May and June. Candidates can enter at any Centre in the United Kingdom where the examinations are held. A list of these Centres, which are about five hundred in number, with the general regulations, etc., can be obtained at the offices of the Society (John Street, Adelphi, London, W.C.), price 1*d.*, post free 1½*d.*

Information about the examination can be obtained from the offices of the Society, but no application for entry to the examination can be received there. Intending candidates should apply to the secretary of any of the Examination Centres for the April examination not earlier than February 1st, and not later than March 9th; for the May–June examinations not earlier than March 10th and not later than April 11th. Late applications will not be accepted.

The Society's examinations are arranged in three stages—Stage III., Advanced; Stage II., Intermediate; Stage I., Elementary. An examination paper in English for foreigners will be set in the Intermediate Stage and in the Elementary Stage. The ordinary standard of the Society's examinations will be strictly maintained, and candidates who have only an elementary knowledge of English are strongly recommended to enter for the Stage I. examination. If they enter for Stage II. (Intermediate), and are not successful, no certificate will be awarded. Candidates can, if they choose, enter for both stages; but this course is not recommended, and it involves the payment of two fees.

At all Centres outside the Metropolitan area the following will be the dates for the examination: Stage I., Monday, April 10th, and Monday, May 29th, commencing at 7 p.m. Stage II., Thursday, April 13th, and Thursday, June 1st, commencing at 7 p.m.

In London (this includes the area known as the Administrative County of London) the Society's examinations are under the superintendence of the London County Council, which is the local Education Authority for the Metropolis. The examination in Stage I. will be held only on Monday, April 10th, and that in Stage II. only on Thursday, June 1st. In both cases the hour will be 7 p.m. Applications to sit at the examinations in the London area should be sent within the dates before mentioned to the London County Council Education Offices, Victoria Embankment, London, W.C.

No application for general information should be addressed there, or to any other Centre, but only to the Royal Society of Arts.

In the Intermediate Stage certificates of a First and Second Class will be given. The minimum percentage of marks for these classes is 70 and 40 respectively. In the Elementary Stage the certificates will be of one class only. To gain a certificate, 50 per cent. of the total marks must be obtained.

A fee of 2*s.* 6*d.* will be charged for each candidate in the Intermediate Stage, and a fee of 2*s.* for each candidate in the Elementary Stage. The Local Committees are authorised to charge a fee to cover their expenses. It is hoped that this fee will not exceed 1*s.* per candidate.

All fees must be paid at the time of application, and at the Centre where the candidate desires to be examined.

Intending candidates will find all other details about the examinations in the before-mentioned publication, including a list of the Examination Centres.

The following are the syllabuses for the two stages:—

Stage I.—Elementary.

The examination paper will include:—

1. Translation into English of an easy French passage.
2. Translation into French of an easy English passage.
3. Rendering into French of English sentences and expressions.
4. A short essay or a letter in English on a given subject.

Candidates for this stage will not be expected to have an extensive vocabulary, and the rendering of the less common words in the translation tests from and into English may, if necessary, be given.

Stage II.—Intermediate.

The examination paper will include:—

1. Translation into English of one or more selected French passages.
2. Translation into French of one or more selected English passages.
3. Translation into French of English sentences and idiomatic expressions.
4. Other questions may be set to test the candidate's knowledge of the English language.
5. A short essay in English on a specified subject.

II. ORAL EXAMINATIONS.

These will be held under the same conditions as the Society's Viva Voce Examinations in

other modern languages, viz., at any date, at any of the Society's Examination Centres, when the Local Committee will undertake to make the necessary arrangements, and to pay a fee of 2s. 6d. per candidate for not less than 24 candidates.

Full details of these examinations will be found in the Examination Programme for 1916 (p. 13), and in the smaller publication containing the list of centres, etc. (p. 13).

It is suggested that any Local Committees desiring to hold a Viva Voce Examination in English should fix a date after the written examination in April.

Arrangements will be made for an examination in London in the month of June. Particulars will be supplied to any intending candidates, who may apply, not earlier than May 1st, to the Secretary, Royal Society of Arts, Adelphi, W.C.

PROCEEDINGS OF THE SOCIETY.

FOURTH ORDINARY MEETING.

Wednesday, December 8th, 1915; Dugald Clerk, D.Sc., F.R.S., Chairman of the Council, in the chair.

The following candidate was proposed for election as a Fellow of the Society:—

Bennett, John, 57, Telford-avenue, Streatham, S.W.

The following candidate was balloted for and duly elected a Fellow of the Society:—

Thain, James Edward Vyner, C.S.P. College, Exmouth, Devon.

The paper read was—

THE ART OF FINDING YOUR WAY AT NIGHT WITHOUT A COMPASS.

By Lieut.-Colonel W. A. Tilney, F.R.G.S., F.R.A.S., late 17th Lancers.

With so much fighting now done at night, this art would appear to be most useful for soldiers to learn. The following is a brief account of its development and solution.

During the South African War I was often sent on long-distance night reconnaissances, and sometimes had Colonel Benson, who led the attack at Magersfontein, as a companion. We noticed that the Colonials, South Africans and natives were quite at home in the dark, whereas men from the British Isles were blind and helpless and lost their way when only a short distance from the column.

Colonel Benson often told me about the attack at Magersfontein, and described the difficulties of a night attack when the whole operation is dependent on one man with a compass.

As an aeronaut in Ladysmith, I had plenty of opportunities of foreseeing the great power aeronautics would have in warfare in the future, and that most of the effective fighting would be done at night.

At that time the Regulations described night operations as extremely hazardous, and warned the commander who undertook such operations that he did so at his own peril and was responsible for the results. Various expedients were suggested to enable the troops to keep their direction, such as that the route should be previously reconnoitred and marked by tins, pieces of paper and other devices; but how the reconnoitring party were to carry out this operation nobody has yet been able to understand. We found the Colonials never required this artificial help, and could move about on a starlit night as easily as in daylight and as fast as the nature of the ground permitted, whereas our Regulations laid it down that local guides should be procured, the route fixed by compass-bearing, and that the pace would rarely exceed two miles an hour.

With the whole operation dependent on the guide, and each individual blind and helpless in the dark, it is little wonder that the Regulations described a night attack as extremely hazardous. We foresaw if only we could devise some simple method for finding your way at night, which could be easily learnt by the rank-and-file of the Army, it would have a far-reaching influence on night warfare. In 1903, on my return to England, I took up the problem of "How to make a simple and practical use of the heavens," and ascertained from various Colonials, Basutos, Indians, and Arabs that they could instinctively read the heavens as a compass, this knowledge having been transmitted from father to son for generations.

My idea was to work out the exact movement and direction of the largest and most easily distinguishable lights in the heavens, so that the least educated had only to be able to recognise these signs by sight and their whereabouts would be known for every hour of the night. Thus the whole dome of the heavens would become a compass.

In 1904 I went through a six months' course at the Royal Geographical Society, under Mr. Reeves, in the hope that we should be

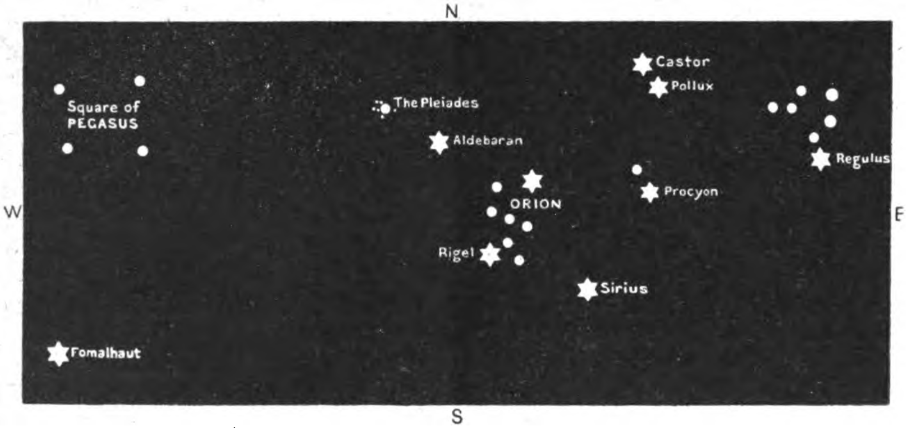

FIG. 1.

able to work out the positions of these various heavenly bodies, but found that the only means of doing so was by observation with a sextant or other instrument and the help of logarithms, etc.

Each observation and calculation took at least twenty minutes, so that to have made a calendar of the heavens by observation was an absolute impossibility.

Some of the highest navigating authorities took a keen interest in the idea, and I am deeply indebted to Mr. Reeves, Captains Nansen, Scott, Armitage, Smith and Blackburn for the help they gave me.

It was not until 1907 that we were able to get stars' bearings mechanically with the help of an orthographic projection of a sphere. Mr. Reeves' astronomical compass originated from this method. In 1909 Captain Blackburn, nautical adviser to the New Zealand Government, sent me his A B C Tables, and I then commenced to make a time-table of direction stars for use in India. We found when the true bearing of various first magnitude stars was known, that it made all the difference to night operations; unfortunately we could arouse little official interest in the project, for anything to do with astronomy was considered too complicated for the average soldier.

However, in 1911 Captain Weatherhead, Naval Instructor, Royal Navy, brought out a little book, with a foreword by Sir Robert Ball, in which he drew attention to the system I was then endeavouring to perfect, and, having received satisfactory reports from various cavalry regiments, I had every hope that the system would be of the utmost value to the Army, if we could only get it well known before the European war cloud had burst. In 1912 it was amply proved that troops could march with ease, rapidity and precision on a starlit night, now that the largest stars were labelled in the heavens, and soldiers began to realise that the ability to make long-distance rapid night marches gave troops the power to strike an enemy from a distance, if necessary, across

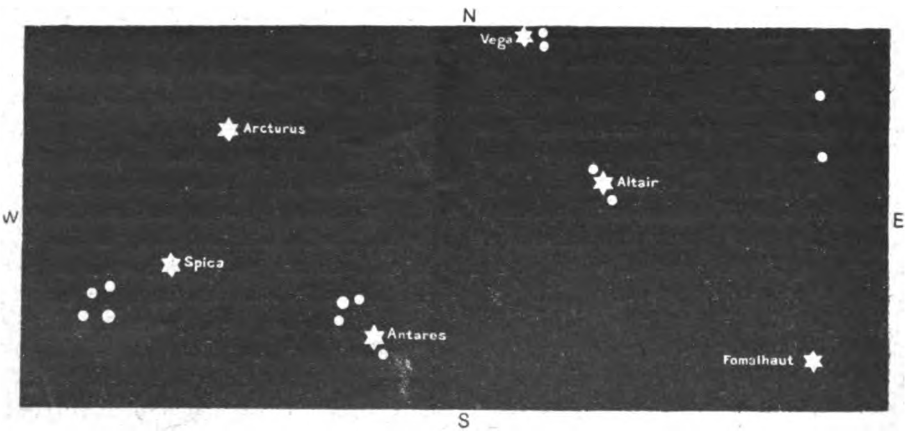

FIG. 2.

country, and that this system was an enormous improvement on old methods, especially in such countries as India and Egypt.

In June, 1913, being certain we were now on the straight road to overcome most of the difficulties connected with night operations, I made the double journey from Sialkot to Quetta to lecture to the Staff College, where I knew they would give the system a thorough good testing. The heat across the Sind Desert at this time of the year is terrible, and many of my friends warned me that such a journey at the hottest time of the year, with only four days' rest at Quetta, would tax the strongest constitution; but feeling sure that the Great War was not far distant, and that in case of any trouble in India this new power to make rapid night marches *without the help of guide* would be of the utmost value, I made the journey.

Severe tests were carried out, and the authorities reported: "we are perfectly certain that the system is a *most eminently sound one*," whilst the Indian Cavalry School reported: "The system has been tried at Saugor and has worked very well indeed. The students found no difficulty in determining the direction stars, and it is obvious that the faster the pace the truer is the direction." On my return to Sialkot, I realised that my friends' warning was true, and that unless I could get out of the heat I was done for. Fate decreed that I could not get home, and I almost died of heat stroke at Sialkot, so could not complete the tables for use in Europe till August, 1914, when Sir Douglas Haig wrote a foreword commending it to the notice of officers and men.

But it was too late, Armageddon had begun, and the work which I had hoped would be invaluable to the Army in this crisis was of no avail. Many officers affirm it would have saved hundreds of lives and casualties had this natural method been known at the earlier stages of the war; so let us explain the system in a few words, and then see how it would have affected

(*a*) The individual in open and trench warfare;

(*b*) Bodies of troops; and further.

(*c*) How rapid night marches can be conducted with ease, rapidity and precision on a starlit night.

The System.

Let us imagine fire balloons or beacons to be placed in the heavens north, east, south, west; it would then be easy enough to go in those directions. Similarly, if you wished to go, say, a hand's-breadth, to the right or left of the beacons, you could easily do so. The stars mentioned in "Marching or Flying by Night without a Compass" (published by Rees, 5, Regent Street, London, price 1*s.*) are the largest in the heavens and act as your fire balloons or beacons.

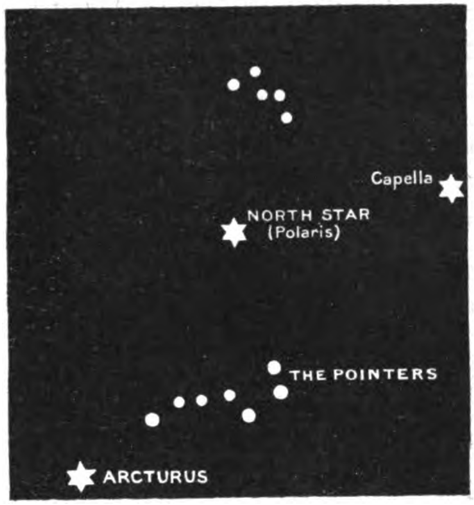

Fig. 3.

Now, if you put the front buttons of your coat on the North or other direction stars, your right and left breasts give you an angle of 45 degrees from the star and your shoulders a right angle. Also, it is only a matter of a little practice to be able to measure 15 degrees of horizon with your hand, so you can get any number of degrees to the right or left of your direction stars, and after a little practice it becomes second nature to recognise the points of the compass at sight, and you acquire the

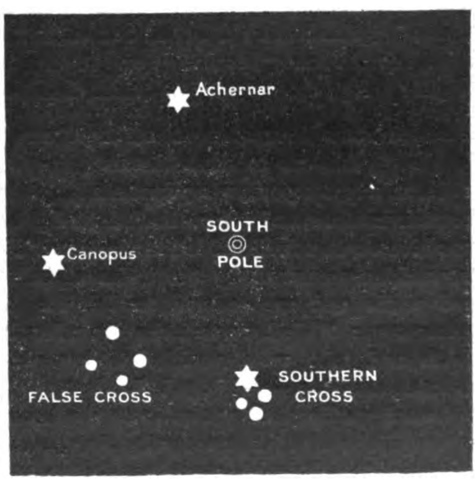

Fig. 4.

same sense of direction as bushmen, Arabs, and people who live far away from civilisation.

The North Star, Altair, and Vega are all-sufficient night guides for the rank-and-file during the spring and summer. For autumn and winter, the North Star, The Sword and Belt of Orion, Procyon and Regulus.

Its Influence on Night Operations.

At the present moment almost every individual from the British Isles is blind and helpless at night.

Let us remove this helplessness and we shall

(1) Give him confidence and self-reliance when engaged in night operations;

(2) Give him a sense of direction, so that he will not fire or dig trenches in the wrong direction;

(3) Be able to send individuals on messages and all communications will be much facilitated. Further,

(4) Slightly wounded men will not wander towards the enemy's lines.

(5) If we have to make an attack or retirement on a starlit night the whole brigade will know the line of attack or retirement, and so endless confusion will be obviated.

(6) Similarly, in the attack every man will know what he is doing, and it will be possible to rally in any desired direction.

(7) The stretcher-bearers will be able to go far afield and pick up the wounded.

Numerous other obvious advantages could be enumerated, for every man will be able to read the natural compass which has been in use ever since the world began, and this knowledge is attainable without taking much trouble, simply by observing the heavens when out at night and expending 3*d.* on the "Soldier's Night Guide" (published by Gale and Polden, Aldershot), or 1*s.* on "Marching or Flying by Night" (Hugh Rees, 5, Regent Street, London).

Finding your Way without a Map, Compass, Watch, or Star Table.

Let us suppose you are a private in the retirement from Mons, and after a hard day's fighting you bivouac in a field and fall fast asleep. You are suddenly aroused by the whizz of bullets and shells and are ordered to fall in. An officer says: "We have to retire five miles due south and take up a position to cover the retirement of the —— Brigade." Just as you are moving off a shell sweeps away the leading troops of the battalion, and by the time you are re-formed the advanced troops have disappeared. It is a pitch-black night with stars intermittently visible; between the clouds you see Vega, a very large bluish star with two little ones near it, making the letter V, almost half-way down in the heavens, which gives you roughly west, so you put your right shoulder on it and march south. Soon after you catch a glimpse of Altair, half-way down in the heavens, which gives you south-west, so if you go half left from Altair you will be going south. The troops around you have got badly knocked about, the country is rolling downs with occasional woods, and each time you have caught a glimpse of one of your direction stars you have taken some object to march on. You stop to help a pal who is badly hit, and as you look towards the north there is not a trace of the North Star or any northern constellation. You lay your pal in a cottage and then resume your journey. Vega and Altair are clouded over, you look eastwards and see Aldebaran rising, which gives you east, so you put your left shoulder on it, take a point to march on, and pursue your journey until you come across a battalion entrenching themselves on the rise of a hill.

Finding your Way to Trenches at Night.

Although the system was only perfected in June, 1915, soldiers of all ranks have begun to realise the simplicity and wonderful utility of being able to read the universal compass, the heavens, and we begin to hear how useful this knowledge has been found for guiding supporting troops up to the first-line trenches, etc.

The heavens cannot go wrong, and on a starlit night you can rely absolutely upon them to take you to your destination, once you grasp the rudiments of the system; you only require to know three or four first magnitude stars, for their exact position is given for every hour of the night in "Marching or Flying by Night without a Compass"

Let us see how it is done.

Say in Flanders on November 1st your battalion has to relieve another between 8 and 9 p.m. in an unknown line of trenches in a direction due east.

Look at the time-table of direction stars and you see the Pleiades (a large bunch of stars that nobody can mistake) is

$$\frac{85}{\text{E f N}} \text{ at 8 p.m.}$$

$$\frac{95}{\text{E f N}} \text{ at 9 p.m.}$$

Put this information in regimental orders, and when the battalion gets to the starting-point, the N.C.O's say to the men: "Do you see that ——— bunch of stars? The line of trenches we have to occupy is two miles from here in that direction; after you have gone one and a half miles you will come to a metalled road running north and south."

On arrival there the battalion will halt, close up and re-form. Every man then knows the line of advance, and on a starlit night they can move with ease, rapidity and accuracy.

Whatever direction you wish to go in, you will always find a convenient guiding star for any hour or hours of the night. Naturally, if you want to send messengers to the rear, all they have to do is to put their back on the Pleiades and their right shoulder on the North Star (if visible) and they will be going back to the starting-point due west.

That is not very difficult, and it has already been the means of saving many a man's life and getting troops out of difficulties.

Now let us deal with Larger Bodies of Troops.

Let us assume that the rank-and-file have been instructed in the art of finding their way at night and are now as night-perfect as any colonial, their fighting efficiency is increased 100 per cent., they are changed beings, and, like Basutos, are trained night fighters who can attack at night.

The great difficulty when large bodies of troops are making a converging attack is to keep direction, the whole advance being dependent on the guide or directing Staff officer.

Now, presuming all ranks can recognise their direction by a glance at the heavens, the Staff officers and leaders can proceed as fast as the ground and conditions permit, with ease and accuracy, by plotting out the star-bearings.

The Regulations say: "The most favourable conditions for night operations are a clear starlit night."

Example of a Converging Night Attack.

Say in Lat. 50° N. on December 1st two columns, A and B, have to make a converging attack on a line of trenches one and a half miles from the position of deployment.

Column A, direction of advance due east

Column B, direction of advance, south-east.

Time for moving off, 11 p.m.

The Staffs look up the respective guiding stars and ascertain, for Column A, Castor is due east at 11 p.m.

$$\frac{100}{\text{E. f N.}} \text{ at 12.}$$

also Regulus due east at 12.

This information should be passed to all ranks, and to obtain great accuracy bearing-cards as follows may be plotted, although when stars are as convenient as the above there is really no necessity to plot.

Bearing-card for Column A.

Point the star-bearing line towards Castor and follow the direction line.

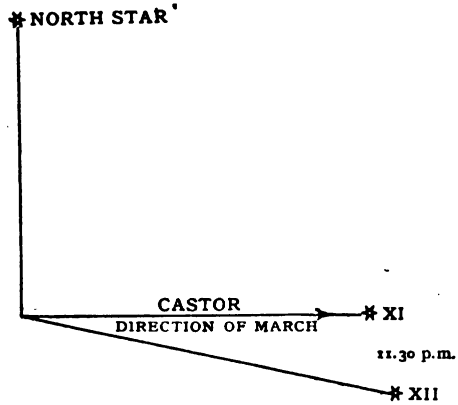

Fig. 5.

For Column B, direction S.E.

Sirius is S.E. at 11 p.m.

$$\frac{150}{\text{E. f N. at 12.}}$$

Of course, 45 degrees to the south of Castor and Regulus would also give S.E.

These should be plotted on a full-size card.

Bearing-card for Column B.

Several divisions who practised this form of attack under natural conditions had these bearing-cards lithographed off in the afternoon and distributed to the leaders, and it worked very well indeed.

The obvious advantages of attacking by star-bearings are:—

(1) All bodies of troops are moving on true bearings in the same direction and can move as fast as the ground permits.

(2) All ranks know the direction and what they are doing. Their confidence and self-reliance is therefore increased.

Besides the advantages mentioned above, it has been found that distances, intervals and

communication can be easily kept up and the formations can be changed according to the

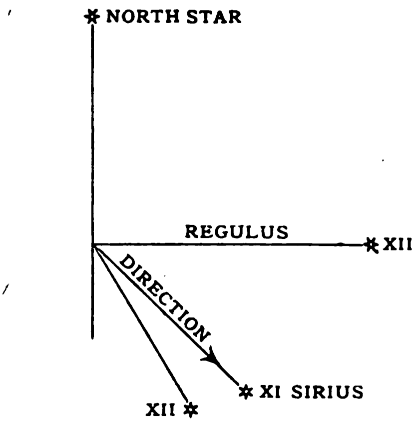

FIG. 6.

nature of the ground. In short, most of the endless confusion connected with night operations is avoided.

RAPID NIGHT MARCH ACROSS COUNTRY.

I have purposely kept the example of a rapid night march till the last, as, except in such countries as Asia Minor, there is little scope in these days of trench warfare for bringing into play this new power to strike an enemy at a distance.

Say, in Persia, Lat. 30° N., on September 15th (time-table of "Direction Stars for India"), a mounted column wishes to make a long-distance rapid night march, in order to surprise an enemy's encampment twenty-five miles distant.

Direction of march due west, country open and passable for all arms. There is only one road which goes through some hills to the north, and the enemy holds these positions in strong force.

On examining the map, a bee-line shows no very serious obstacle; but in order to check distances covered, and to ensure that the column is keeping an accurate direction, the following features are noted on an ordinary piece of paper in large black figuring, thus :—

Distance.	Feature.
After going 2 miles.	Stream.
,, ,, 4 ,, further.	Unmetalled road running N.E. and S.W.
,, ,, 5 ,, ,,	Sugar-loaf hill.
,, ,, 4 ,, ,,	Small village.
,, ,, 3 ,, ,,	Strip of cultivated ground.
,, ,, 5 ,, ,,	Village at the foot of low line of hills.
23 miles.	

The column halts, scouts are sent forward to ascertain the exact whereabouts and dispositions of the enemy.

On the reverse side of the card or piece of paper the following information is given :—

GENERAL DIRECTION WEST.—DIRECTION STAR, VEGA.

Time.	Bearing.
IX.	$\frac{55}{\text{W. f N.}}$
X.	60
XI.	60
XII.	60
I.	55
II.	50
	W. f N.

We will allow six hours for the twenty-three-mile march, including halts (it was found in numerous test marches with mounted troops that five miles per hour could be comfortably covered over easy country); so, as Vega has set at 2 a.m., we must switch on to another star for the last hour. On looking at the time-table of direction stars, we see Fomalhaut is

$$\frac{135}{\text{W. f N.}} \text{ at 3 a.m.,}$$

so 45 degrees to the right of that star will give us due west.

Here are the bearing-lines for the march, but they are really not required when using such a constant star as Vega is in this case.

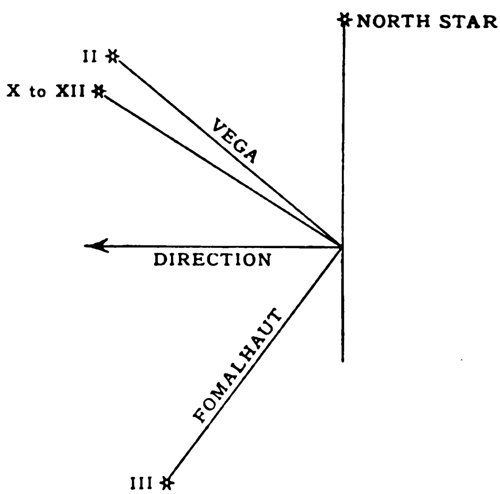

FIG. 7.

In all night work this power to read the heavens will be found to be extraordinarily useful, for if the body of troops has a guide you can see in a moment if he is taking you wrong.

Now some will say to themselves: "What happens if the heavens become overcast whilst you are on this long night march? You will have to creep along at two miles per hour on compass bearings."

This difficulty has recently been overcome by the invention of the Ani-Pace Compass (Hugh Rees, 5, Regent Street, London), an instrument with no magnetic variation, which gives true bearings, can be read by touch and sound, and once set is unaffected by oscillation. When any stars or heavenly bodies are visible it at once gives their true bearings and obviates the necessity to draw out the star-bearing and direction lines, as above described.

When no stars are visible, it enables you to proceed on true bearings as fast as the nature of the country permits.

So we have conquered most of the difficulties connected with night operations and, as Sir Douglas Haig says, the method has been tested and found successful. Another well-known authority remarks: "The system is exceedingly useful because it is so simple, and is just what was wanted in the Army when so much fighting is done at night; it will be of the greatest service to others besides soldiers."

If these predictions are fulfilled, and it proves to be a real service to the Army in this great crisis, those who have helped to perfect the system will be more than well rewarded.

I will now show you the direction stars on the screen, and teach you in five minutes how to find your way at night without a compass, star-table or any instrument. After that I shall be most grateful for your fullest criticism.

At the conclusion of the reading of the paper, a number of questions were asked by members of the audience, to which Colonel Tilney replied; and, on the motion of the Chairman, a hearty vote of thanks having been accorded to Colonel Tilney for his interesting and instructive paper, the meeting terminated.

COLLISIONS AT SEA.

At a recent meeting of the Royal Society, Professor J. Joly, Sc.D., F.R.S., read a paper on "A Method of Estimating Distances at Sea in Fog or Thick Weather." The method proposed is based upon the different velocities of disturbances in differing media. If aerial and submarine signals are simultaneously emitted at a lighthouse station or lightship, the lag of the aerial compared with the submarine sound is about 4·3 seconds to the nautical mile. An approaching ship picking up the signals and measuring the lag to an error even of one second becomes aware of her distance to less than one-quarter of a mile. Similarly wireless signals and submarine signals, or wireless and aerial signals, may be used.

If the faster moving signals be sent out in groups, the individual signals, being spaced to regular intervals, say, of one second, and the slower moving signal be always emitted simultaneously with the first signal of a group, the navigator has only to count the faster signals till the slower signal reaches him, in order to estimate his distance from the signal station. In this case the signals themselves tell him his distance, and no actual time-measurements are required on board ship.

It is shown that this system enables the mariner to determine his position completely under all circumstances which may arise.

Professor Joly also read a second paper dealing with an extension of this method to the problem of avoiding collision in fog.

It is shown that if vessels possess the means of emitting a loud and crisp sound signal which can be sent out simultaneously with a wireless or a submarine signal, the determination of distance rendered possible thereby, along with wireless information as to course and speed, will enable the navigator on each ship to determine with certainty (1) whether there is risk of collision or whether there is no risk, and (2) the point upon his own course and the moment at which collision is threatened.

The solution of the problem is based upon the fact that at each instant the rate of mutual approach is the maximum if the ships are advancing so as to collide. A simple geometrical construction, which by its character is unlikely to involve error, enables the mariner to solve the problem immediately the signals are received.

CASEIN FROM INDIA.

The *Indian Textile Journal* gives some particulars of the manufacture of casein in India. Owing to difficulties of transport, it is in many places impossible to distribute milk in a fresh condition. By converting it into casein, a dry, non-decaying substance that may be packed in boxes or bags, it may be carried with ease, and it finds a ready sale for use as a substitute for celluloid, over which it has the advantage of not being inflammable. For some years a profitable business has been conducted at Anand, in the Baroda State, in the production of casein for export. The process resembles the manufacture of cheese. The skimmed milk is coagulated by rennet, precipitated by hydrochloric acid, and separated in a centrifugal filter. The result is a whitish or yellowish mass which, after drying, is the casein of commerce. There are several ways of separating it, one of the most recent being by a current of electricity, which is said to be the cheapest where current from water or wind power is available.

Casein has also been extracted on a large scale

from the soya bean after the oil has been removed by pressing. One of the most important uses of casein is the production of galalith, which is used to imitate ivory, tortoiseshell, and celluloid. It is cheaper than the last-named substance. Galalith is made from casein by pressure, which forms it into cakes that are then compressed to the desired thickness. It is translucent, and can be given any colour. It has no bad odour, and will take a high polish. When heated to 150° C. in a bath of oil, it can be moulded by pressure. It is already used for a great variety of low-priced articles, including waterproofs, that do not soften and stick together like rubber goods in a tropical climate. It is made into plates, rods, and tubs, like ebonite. Galalith factories are increasing in number in Europe. In 1910, at Lurgère (France), 440,000 lb. of casein were converted into galalith — the produce of thirty-five dairies that sent their milk to the factory. It takes 15·85 gallons of milk to produce 2·20 lb. of galalith.

Milk casein is also used for sizing paper which is waterproof and resembles parchment. Silks, artificial textiles, leather, films, and plastic substances are prepared with the aid of casein, and in printing calico a solution of vegetable casein and borax is sometimes used as a thickening agent, which adds brilliancy to the colour and gives a silky appearance.

THE EXPORT FRUIT INDUSTRY OF NEW ZEALAND.

During the planting season 1914 has occurred the greatest development in laying out apple orchards that New Zealand has yet experienced. Some quarter of a million fruit trees—mostly apples of approved commercial export varieties—have been planted.

The Nelson district has always led the way in orchard planting; illustrative of this is the fact that apples exported from Nelson Province in 1912 totalled 18,000 cases; 1913, 33,000 cases; 1914, 66,000 cases. The 1915 season promises greatly to exceed the 1914 season.

Most of the work of new planting has been carried out by large companies acting on behalf of intending orchardists who are not yet resident. The methods adopted by these companies are similar in each case. A supervisor, who is a fruit expert, is appointed for each estate, and a staff of men under him are engaged. The whole of the planting work, including clearing, ploughing, purchase of trees, fencing, etc., is carried out under this supervision; and by this staff the orchards so planted are maintained, under the same management, until in bearing, spraying, pruning, cultivating and all necessary work being carried out by them. This method is agreeable to many purchasers, as it enables men, who could not otherwise afford the five or six years' wait, to remain in whatever position they may hold until their orchard is a revenue-producing concern.

The varieties of apples favoured in the Nelson district are Cox's Orange Pippin, Jonathan, Sturmer, Munroe's Favourite, Delicious, Scarlet Nonpareil, Washington and Alfriston.

Shipping facilities from the Nelson district are provided by three ports. The Nelson harbour is, of course, the largest, but both the western entrance and the Motueka harbours are capable of taking and loading coastal boats to carry the fruit to Wellington for sale or for transhipment for export to the Northern Hemisphere and to South America.

Dealing with other districts, extensive planting is proceeding in North Auckland this year. It looks, with the enormous area of land available, as if the apple output from this district will in years to come exceed that from Nelson. The varieties planted are somewhat different, the most successful being Doherty, Northern Spy, Gravenstein, American Horn, and Lord Wolseley.

Central Otago is also pushing ahead with smaller areas, and individual growers are turning out splendid fruit. Up to date all this fruit has been sold locally for the Dunedin market.

With regard to markets, at present South America is the greatest consumer of New Zealand apples. The buyers from this continent are demanding more fruit than New Zealand can supply. This may not, however, always be the case, as in four years' time it is anticipated that the Dominion will be able to export from a million and a half to two million cases of apples per annum. It is therefore necessary for the growers to organise in order to develop further markets in other parts of the world. According to the report for 1914 of the Wellington Chamber of Commerce, there should not be any very great difficulty in organising these markets, but the day of the individual grower marketing his own fruit is rapidly passing away. It is desirable that co-operative societies or companies be formed whose functions would include picking, grading, and cool-storing of the fruit of the surrounding growers. This could be handled by co-operative companies, with growers as members, on similar lines to co operative dairy companies. The advantages of co-operation in the preparation of the fruit for market and in selling the fruit are evident. A brand could be established for large quantities of fruit graded by experts, instead of a number of different brands each for small quantities of fruit, and uniformity in the quality of fruit supplied could be ensured. Buyers from other parts of the world will not deal with small quantities of fruit, and they must be absolutely sure that the fruit supplied will be regular in size, colour, and quality. Too much stress cannot be laid on the necessity for co-operation, and the leading men in the industry seem fully alive to this fact.

This year, in spite of the somewhat dry season, in all probability over 100,000 cases of apples

will be exported. South Americans are offering at from 6s. to 7s. per case f.o.b. Wellington. The present apple export trade from New Zealand is not large, but it is evident it will show enormous development within a few years. Growers of apples for export must realise that their product has to compete in the world's markets. It is essential, therefore, that every care be taken in growing fruit suitable for particular markets, that the quality and colour are right, that the apples are uniform in size and adequately packed. There is no reason why fruit co-operative packing companies should not do for the apple-export industry what the co-operative dairy factories have done for the dairying industry.

ENGINEERING NOTES.

Railway Progress in China.—Nearly forty years ago the first attempt to construct a railway roused the Chinese to such fury that the mob tore up the rails and pitched them into the sea. Later on calmer counsels prevailed; but it was not until the year 1878 that the first rail of the famous Shanghai-Woosung line was laid by Mrs. G. J. Morrison, an Englishwoman. A 30-in. gauge, with 26-lb. rails, was adopted. A locomotive called the "Pioneer," weighing only 22 cwt., specially designed in England, made the first locomotive run on February 14th of that year, that is, exactly fifty years after the "Rocket" made its debut. Through the cleverness and persistent efforts of the promoters, the road was finally completed, the total distance being some seven miles. Step by step the extension of railways went forward. Thus in 1907—that is, when the "localisation" movement had started—important lines such as the Pekin-Mukden, the Pekin-Hankow, the Pekin-Kalgan, the Tientsin-Pukow, the Shanghai-Nankin, the Kirin-Changchun, the Chengtai, the Canton-Kowlun, the Chuping, the Pien-lo, and the Tao-Ching railways, etc., with a total length of more than 4,000 miles, were all for the greater part open to traffic. The first railway of importance financed entirely with Chinese capital and built by Chinese engineers was the Pekin-Kalgan line, which is a short section of about 125 miles of the Pekin-Suiyuan Railway, the whole system being about 400 miles. It passes through very difficult country. In fact, from an engineering point of view, it is the most difficult line now existing in China. Starting from Fengtai, where it connects with the Pekin-Mukden line, it proceeds in a northern direction, along the west wall of Pekin, to the Nankow Pass, in the neighbourhood of the Ming Tombs. This section of about thirty-three miles is comparatively easy; but from this point up, for a distance of about fifteen miles, including the Nankow Pass, where the altitude suddenly rises to over 2,500 ft., the country is difficult. The road winds along deep gorges and high mountains, necessitating four tunnels aggregating a mile in length and numerous bridges, viaducts, deep cuts, and high embankments. At first many people thought that it was almost an impossible piece of engineering work. For some of the above details we are indebted to the *Manchester Guardian.*

A Pioneer in Aviation.—Recently at Sydney, N.S.W., Lawrence Hargrave passed away, a noted man in many ways, particularly in the science of aviation before it reached its practical stage. The late Mr. Hargrave, who did so much to advance the science of aviation, was born in England, but he spent the greater part of his life—forty-eight years of it—in New South Wales. He was the son of the late Mr. Justice Hargrave. The death of his own son, Geoffrey Hargrave, who was killed at the Dardanelles a few months ago, was a great blow to him, and undoubtedly hastened the end. Geoffrey Hargrave, like his father, was an engineer by profession, and his death in action has cut short a very promising career. The name of Lawrence Hargrave will be remembered the more as time goes on. He worked for some years as an assistant astronomical observer at Sydney Observatory, but gave up his work there and thereafter devoted most of his life to the study of aeronautics; and certain it is that the present-day successes in mechanical flight are due largely to the work of this man. Thirty years ago Hargrave was studying the flight of birds, making working models embodying the principles of their motions. The success of the models convinced him of the possibility of mechanical flight; and in a paper which he read before the Royal Society of New South Wales in 1884, he gave particulars of his discoveries in modest and simple terms. "I have strung together my thoughts, experiments and deductions that refer in any way to the trochoidal plane," he said, "pointing out where I see Nature working with it, and how it can be used by man for the transmission of force; and I think that if other members have heard of or made similar observations they should bring them forward, so that my mistakes may be corrected by comparison with the ideas of others, and also that the truth may be elicited about a matter that does not seem to get its fair share of investigation. The trochoidal action of five muscles and legs seems so plain that I could not help being led to theorise on the action of wings in flight. I say theorise, because I have not a flying machine to show you; but the chain of evidence is so complete that I have no doubt it soon will be accomplished, without the aid of the screw or the gas-bag. These are my views, and if you think there is any novel truth embodied in them, this society is welcome to any of the laboratory models that aided me in finding it out." Eleven years later, in 1895,

Hargrave conducted a remarkable experiment, utilising his invention of the cellular or box kites, the forerunner of the modern aeroplane, to lift him from the ground. The principle was adopted by practically every military nation in the world for signalling purposes. Other papers of his have obtained a European reputation. It was Hargrave who lifted human flight from the realm of dreamland into realisation; it was upon his discoveries that other men built, who have become famous in the world of aeronautics—the Wright brothers and Farman, for instance. For thirty years he worked steadily on the problems of aerial engineering, constructing models, improving on them, and ever reaching higher stages. It is said of him that for one of his boilers he required 190 ft. of copper tubing, and, finding that the pipe on sale in Sydney was too thick for his purpose, he shaved the 190 ft. to the thinness required, and had to invent a lathe to do it. And all the time, whilst his work was unappreciated, and his efforts had even ridicule heaped on them—aeronauts in other lands were working on his ideas. It was but one more illustration of the truth of the saying that a prophet is without honour in his own country. It is not to our credit that when, some years ago, Mr. Hargrave offered to hand over all his models to the Australian Government, so that they might be available for inspection by other inventors and the public generally, they could find no room for them anywhere. The same indifference was shown in England. So they were presented to Germany, and to-day they may be seen in the Deutsche Museum at Munich, and it is believed that the "Taube" aeroplane, which has been so prominent in the war, is fashioned on one of these Australian models.

Closure of the Hell Gate Arch at New York.—Recently the south bottom-chord section forming the first connection between the east and west halves of the 977 ft. 6 in. Hell Gate arch of the New York Connecting Railway, the longest arch-span in the world, was fitted into place with 3½ in. to spare. The member was raised and set in twenty-five minutes by the two travelling cranes which had been built on each side of the arch. The closing member of the north truss was successfully set in the same length of time, although the hot sun had expanded the bridge till there was less than 2 in. clearance in which to manipulate the 90-ton chord section. The two diagonals from the top of the east side of the panel to the bottom of the west side were next set with half the diagonals from the bottom of the east side. The closing panel is a true centre panel, and the temporary hinged bearing that will support the arch till the full dead load is being carried is in the bottom chord at the west end of this panel. The next day the jacks on the main posts of the backstays, which rest on the two main piers, were lowered varying distances from 15 to 20 in. to bring the centre hinge to a bearing. This operation was successfully accomplished, and the eyebar-ties over the backstay posts were released in about one hour and a quarter, through the use of a multi-party telephone line with stations at the centre, at each backstay jack, at each counterweight, and at the office. Men stationed at all these points were thus kept continually informed of all relative movements, each station being directly connected with all the others, and all "listening in" to the orders and reports from each of the points. Previous calculations of the required movements at each jack had been made to ensure even lowering at the top hinges, so that no appreciable shear would be transmitted through the centre chords. No lives were lost in these operations; safety and accuracy were considered of primary importance. When completed with hangers and floor system there will be nearly 20,000 tons of steel in the arch-span. The east ends of the top-chord sections in the centre panel were at once riveted up, but the west ends will be left free to move until the arch has reached its final position under full dead load. In order finally to match up this panel point it was thought best to leave one pair of members blank and drill by the other pair after the arch was under full load. As temperature changes on any ordinary day would throw this work out of alignment before holes could be drilled to insert enough drift pins to withstand the temperature stresses, some means had to be provided for holding the top-chord sections rigid at this panel point. This is accomplished by a 7-in. diameter bolt inside each top-chord section parallel to its centre line. These bolts are strong enough to take all the temperature stresses and hold the ends of the top-chord sections rigid till they can be drilled and riveted.

The Future Military Aeroplane.—We learn from the *Scientific American* that Germany will soon begin the construction of giant aeroplanes—triplanes—of enormous dimensions. These machines are to be three times as big and strong as the ordinary flying machine. They are to carry as many as twenty men. This crew will work four machine guns and one light field piece mounted in a special little armoured turret. Eight Maybach motors, similar to those used by the Zeppelin airships, are to drive the machine through the air. The motors will be coupled in pairs and drive four propellers. The propellers may be shifted in position, so that they serve for steering in a horizontal plane. Manual steering will be used only for elevating or depressing the machine. All other movements will be effected by the motors. The triplane will fly with two propellers only if need be, and travel at high speed when four are turning. The machine is to be armoured.

OBITUARY.

ZACHARY MERTON.—By the death of Mr. Zachary Merton, which occurred recently in Cadogan Gardens, a number of London charities lose a generous benefactor.

Mr. Merton, who was of Jewish race, was born in England in 1843. His father was of German descent, but was a natural-born British subject. Mr. Zachary Merton was a partner in the firm of Henry R. Merton & Co., and when it was converted into a limited liability company he became a director and one of the principal shareholders.

About 1887 his attention was called to the condition of the many thousands of underfed London children, and to the lack of proper training for poor boys as soon as they left the elementary schools. He consulted Mr. H. Gardner, master of what was known as the Hornsey Road Ragged School, and by his advice he founded and entirely supported a trade school or institute, first located in George's Road, Holloway, and afterwards in larger premises in Holloway Road. This institute has flourished for twenty-eight years, and on it from first to last Mr. Merton spent £11,000. With a similar regard for the health, the rational amusement, and the elementary training in handicrafts of the London children, Mr. Merton for several years subscribed some £750 a year to the Evening Play Centres, which now provide for about 25,000 boys and girls. This sum practically pays the cost of three play centres.

Of various hospitals Mr. Merton was a most generous supporter, and of the Charity Organization Society also. To the latter he contributed, since the war began, £40 a week to meet cases of poverty indirectly caused by the war. He helped other sufferers in other ways, and was specially on the look-out for cases of distress caused by the pressure of the "improvements" which so constantly benefit the many and ruin the few. An instance was his care for drivers of horse omnibuses and hansom cabs, forced out of work by motors and taxi-cabs. Whenever he could he took a hansom, got into conversation with the driver, and if he found him losing his work he arranged to pay for his being taught to drive a taxi-cab.

Mr. Merton was elected a member of the Royal Society of Arts in 1890.

NOTES ON BOOKS.

THE COLONISATION OF AUSTRALIA (1829-42). By Richard Charles Mills, LL.M., D.Sc. (Economics). London: Sidgwick & Jackson, Ltd. 10*s.* 6*d.* net.

The years 1829 to 1842 were the turning-point in the history of Australia. Previously to this period the colony was merely regarded as a dumping-ground for the superfluous and least desirable portion of the population of the mother country, and it received an annual increment of the worst of our criminals. It was known as "the fifth or pickpocket quarter of the globe." British ideas about colonisation could then hardly be said to exist; the condition of colonial land laws was chaotic; and Australia seemed to be heading rapidly for ruin. From this fate she was saved mainly through the instrumentality of one man, Edward Gibbon Wakefield. The great merit of this book is that it gives the first full and adequate analysis of Wakefield's work—a theme which must possess enormous interest for all students of colonial history.

The career of Wakefield is most remarkable. After an idle and profitless youth he found himself at the age of thirty sentenced to three years' imprisonment in Newgate for making a runaway match with a very young heiress, whom he lured from school. What would have meant permanent ruin for most men was salvation for Wakefield. Brought to his senses by the rude shock of his sentence, he devoted himself to the closest study of colonies and colonisation. To the surprise of those who had been his friends, he turned out to be a man of ideas, and his series of "Letters from Sydney" (written while he was still in Newgate) attracted instant attention. He was master of a vivid and nervous style, and so graphic was his account of Sydney that no one suspected the letters to be the work of any one but a colonist. He described the economic, social, and political conditions of New South Wales, and he suggested the remedies which time has proved to be the right ones. As an instance of his prophetic insight, it may be mentioned that he even went so far as to point out the necessity of instituting irrigation works, which has only been thoroughly realised in Australia in recent years.

Mr. Mills gives a terrible account of the conditions of emigration and of emigrants at the time when Wakefield began his labours. A part of Wakefield's scheme was to sell land in Australia in small quantities, instead of the enormous tracts of which the landed estates then consisted, and to utilise the proceeds as a fund to promote emigration. He saw that the great need of the colonies was labour of a good class, and he was remarkably successful in his efforts to secure it.

Wakefield is, perhaps, even more intimately associated with New Zealand than with Australia. In 1837, when the New Zealand Association was established, he became its managing director, and, indeed, by a bold coup he compelled the British Government to annex the country just in time to anticipate a similar step on the part of France. And it was to New Zealand that he went in 1853, after a constitution had been granted to the colony, and he continued to live in Wellington till his death, nine years later.

It is fitting that this tribute to Wakefield should come from Mr. Mills, who himself hails from Melbourne. He has made a very careful and complete study of this remarkable man and his methods, and his book is a notable addition to the series of monographs by writers connected with the London School of Economics and Political Science.

GENERAL NOTES.

Further British Awards at the Panama Exposition.—The second list of awards at the Panama-Pacific Exposition has been received from the British Commissioner at the Exposition. The first list was published in the *Journal* of September 10th last. The following are the successful exhibitors:—*Department of Fine Arts.*—Group I. (gold medal), C. W. Simpson, George Sauter, Julius Olssen, Harold Speed, Laura Knight, H. Hughes Stanton, Harold Knight; (silver medal) W. G. von Glehn, R. G. Goodman; (bronze medal) Louise Ginnett, J. Ker Lawson, Isobel A. Dods-Withers, Herbert Draper, W. E. Christmas, Jane Emmett von Glehn, L. Richmond; Class II. (gold medal), R. G. Goodman. Group II. (medal of honour), Frank Brangwyn; (bronze medal) Alfred Bentley. *Department of Machinery.*—Messrs. John Henry Andrew & Co., Ltd. (tool steel and mining steel), gold medal; Messrs. Edward G. Herbert, Ltd. (tool steel and file steel testing machines), gold medal; Messrs. Seebohm & Dieckstahl, Ltd. (steel manufacturers), gold medal. *Department of Transportation.*—Messrs. Thomas Cook & Son (guide-books, maps, etc.), medal of honour; Messrs. Rolls, Royce, Ltd. (automobiles), grand prize; Coventry Chain Company (chains and gear wheels), gold medal. *Department of Agriculture.*—Messrs. John Gillon & Co., Ltd. (Scotch whisky), medal of honour; Messrs. E. & J. Burke, Ltd. (Dublin porter and Bass's ale), medal of honour; Messrs. E. & J. Burke, Ltd. (sloe gin), medal of honour; Messrs. E. & J. Burke, Ltd. (three star Irish whisky, dry gin, and Old Tom gin), gold medal; Messrs. Cantrell & Cochrane (ginger ale), medal of honour; Messrs. John Dewar & Sons, Ltd. (Scotch whisky), gold medal; Clifford-Wilkinson Tan-San Mineral Water Company, Ltd. (natural aerated mineral water), gold medal. *Department of Horticulture.*—Messrs. Kelway & Sons (flowering annuals), medal of honour; Messrs. Sutton & Sons (outdoor flowering plants), medal of honour; Messrs. Sutton & Sons (seeds), gold medal; Messrs. Sutton & Sons (antirrhinums), gold medal; Messrs. Sutton & Sons (salpiglossis), silver medal; Messrs. Sutton & Sons (Cosmea-miniature yellow), bronze medal; Mrs. Alice Martineau (model of Hurst Court Garden), silver medal.

China's Fishery Schools.—The first fishery school was established at Woosung in 1904 by the Kiang-Chi Fishery Company. The provinces of Chili and Mukden followed successively, and the curriculum in these schools was modelled after that of the Woosung School. Besides these schools there have also been established fishery training schools for the practical improvement of fishing methods. In the third year of the Republic (1914) the Ministry of Agriculture and Commerce started to establish training schools along the coast. Several have already been established in the provinces of Chili, Chekiang, Fengtien, Fukien, and Kwangtung. In the province of Chekiang alone three training schools have been established. The people engaged in the fishing industry all welcome these schools, and it is expected that they will be greatly benefited.

Pomace as Cattle Food.—The Board of Agriculture draw the attention of stock keepers living in cider-making counties to the value of pressed apple pomace as a palatable feeding-stuff for stock. The fresh pomace, which contains from 70 per cent. to 80 per cent. of water, according to the efficiency of the pressing and the variety of apple, should be fed in combination with more concentrated feeding-stuffs, and not as a complete ration in itself. On the basis of composition it has a considerably higher feeding value than mangolds, and is not unlike wet brewer's grains, though it contains less protein. As it ferments rapidly, it should be fed quite fresh; or it may be preserved with salt and made into a kind of silage. When dried the pomace forms a valuable concentrated feeding-stuff.

Argentine Oil Output.—According to official figures issued by the Argentine Minister of Agriculture, the output of the Comodoro Rivadaira oil-fields since the beginning of their exploitation in 1907 is as follows (in barrels of 42 gallons):—

			Barrels.
1907	1	well	101
1908	1	,,	11,472
1909	3	wells	18,831
1910	3	,,	20,753
1911	3	,,	13,119
1912	3	,,	47,007
1913	7	,,	130,618
1914	8	,,	275,500
Jan. 1st to March 26th, 1915	9	,,	85,344

The grand total of all the wells since the commencement of the industry to March 26th, 1915, is 602,745 barrels.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

December 15.—Josef Denyn, Carillonneur de Malines, and William W. Starmer, F.R.A.M., "Carillons and Carillon Playing." W. G. McNaught, Mus.Doc., will preside.

January 19. — Lawrence Chubb, "The Common Lands of London: the Story of their Preservation." Lord Farrer will preside.

January 26.—J. Arthur Hutton, Chairman of the British Cotton Growing Association, "The Effect of the War on Cotton Growing in the British Empire."

February 2.—S. Charles Phillips, M.S.C.I., "Paper Supplies as affected by the War."

FEBRUARY 9.—PROFESSOR J. A. FLEMING, M.A., D.Sc., F.R.S., "The Organisation of Scientific Research." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, will preside.

FEBRUARY 16.—THE HON. LADY PARSONS, "Women's Work during and after the War."

FEBRUARY 23.—MISS H. B. HANSON, M.D., B.S., D.P.H., "Experiences in Serbia."

INDIAN SECTION.

Thursday afternoon, at 4.30 p.m.:—

DECEMBER 16.—C. C. MCLEOD, President of the London Jute Association, "The Indian Jute Industry." SIR JOHN PRESCOTT HEWETT, G.C.S.I., C.I.E., will preside.

Dates to be hereafter announced:—

R. W. SETON-WATSON, D.Litt., "The Balkan Problem."

CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Optical Appliances in Warfare."

REV. P. H. DITCHFIELD, "The England of Shakespeare."

W. A. CRAIGIE, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

VICTOR HORTA, Directeur de l'Académie Royale des Beaux-Arts de la Ville de Bruxelles, "Belgian Architecture."

CHARLES DELCHEVALERIE, "Belgian Literature."

LESLIE URQUHART, "The Economic Development of Russia."

PROFESSOR T. G. MASARYK, "The Slavonic Peoples."

G. P. BAKER, "Hindu Hand-painted Calicoes of the Seventeenth and Eighteenth Centuries, and their Influence on the Tinctorial Arts of Europe."

COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., late Survey of India, "The Romance of the Indian Ordnance Survey."

C. A. KINCAID, C.V.O., Indian Civil Service (author of "Deccan Nursery Tales," "The Indian Heroes," "The Tale of a Tulsi Plant," etc.), "The Saints of Pandharpur." LIEUT.-COLONEL SIR DAVID W. K. BARR, K.C.S.I., will preside.

SIR DANIEL MORRIS, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland."

PROFESSOR WYNDHAM R. DUNSTAN, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India."

INDIAN SECTION.

Thursday afternoons at 4.30 p.m.:—

January 13, February 17, March 16, April 6, May 18.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

February 1, March 7, May 2.

CANTOR LECTURES.

Monday afternoons at 4.30 p.m.:—

WALTER ROSENHAIN, D.Sc., F.R.S., Superintendent, Metallurgy Department, National Physical Laboratory, "Optical Glass." Three Lectures.

Syllabus.

LECTURE III.—DECEMBER 13.—The present process of manufacture—General difficulties—Costliness—Cost of the pot—Time of production—Cost of melting—Raw materials—Low yield of good glass—Risks of the process—Risks of loss during melting—Failures due to striæ—Risks of contamination—Errors and variations of optical constants—Range of glasses demanded by opticians—Small quantities required—Need for large stock of optical glass. Special difficulties in England—Cost of raw materials and of labour—Refractories. Special difficulties connected with "new" glasses—Their chemical activity—Action on pots—Absorption of colouring impurities—Attainment of extreme optical properties. Need for research—The general problem—How to make good optical glass—Necessary improvements in pots and refractories, and in furnaces and methods of working—Utilisation of new materials and electric methods—The special problems relating to individual types of glasses—Optical and other properties to be realised simultaneously—The limitations of possible glasses—Optical properties of crystalline media—Future possibilities.

J. ERSKINE-MURRAY, D.Sc., F.R.S.E., M.I.E.E., "Vibrations, Waves, and Resonance." Four Lectures.

May 1, 8, 15, 22.

FOTHERGILL LECTURES.

Monday afternoons, at 4.30 p.m.:—

REV. DR. HERBERT WEST, D.D., A.R.I.B.A. (author of "Gothic Architecture in England and France"), "Flemish Architecture." Three Lectures.

February 7, 14, 21.

EDWARD A. REEVES, F.R.A.S., Map Curator, Royal Geographical Society, "Surveying." Three Lectures.

March 27, April 3, 10.

Juvenile Lectures.

These Lectures will be given on Wednesday afternoons, January 5 and 12, at 3 p.m. The first lecture will be given by Professor John Millar Thomson, LL.D., F.R.S., on "Crystallisation," and the second by Mr. James Swinburne, F.R.S., on "Science of some Toys."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DECEMBER 13...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cantor Lecture.) Dr. W. Rosenhain, "Optical Glass." (Lecture III.)

Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Professor A. S. Eddington, "The Movement of the Stars."

Engineers, Society of, 17, Victoria-street, S.W., 5.30 p.m. Annual General Meeting.

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. Mr. M. C. Duchesne, "English Timber during and after the War."

Geographical Society, Burlington-gardens, W., 8.30 p.m. Colonel Sir Thomas Holdich, "The Work of the Peru-Bolivia Boundary Commission."

British Architects, Royal Institute of, 8, Conduit-street, W., 8 p.m.

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Mr. F. E. Weston, "Hypo and its Uses."

Microscopical Society, 20, Hanover-square, W., 8 p.m. Mr. J. E. Barnard, "The Use of Ultra Violet Light in Microscopy."

Japan Society, 20, Hanover-square, W., 3.30 p.m. Mr. Yoshio Markino, "Just a few words on the Occasion of the Imperial Coronation."

Alpine Club, 23, Savile-row, W., 8.30 p.m.

East India Association, Caxton Hall, Westminster, S.W., 4.15 p.m. Mr. G. C. Whitworth, "Hindus and Muhammadans."

TUESDAY, DECEMBER 14...Sociological Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.15 p.m. Dr. L. P. Jacks, "A Drifting Civilisation."

Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Professor J. T. Morris, "Recent Developments in Electric Incandescent Lamps in relation to Illuminating Engineering."

British Academy, in the Theatre, Burlington-gardens, W., 5.30 p.m. (Schweich Lectures.) Mons. E. Naville, "The Text of the Old Testament." (Lecture II.)

Asiatic Society, 22, Albemarle-street, W., 4 p.m. Sir C. Lyall, "Some Experiments in Adapting Arabian Metrical Forms to English Verse."

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. (James Forrest Lecture.) Mr. H. M. Hobart, "Electrical Railways."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Professor A. E. Douglass, "Zodiacal Light and Counter Glow, and the Photography of Large Areas and Faint Contrasts."

Anthropological Institute, 50, Great Russell-street, W.C., 5 p.m. Mr. J. R. Moir, "The Evolution of the Earliest 'Chelles' Palæoliths from the Rostro-Carinate Implements."

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. The Hon. B. R. Wise, "Australia and the War."

Electrical Engineers, Institution of (Local Section), 17, Albert-square, Manchester, 7.30 p.m. Mr. J. R. Beard, "The Design of High-pressure Distribution Systems."

(Scottish Section.) Prince's-street Station Hotel, Edinburgh, 8 p.m. Mr. G. Wilkinson, "Electric Heating: Its Present Position and Future Developments."

WEDNESDAY, DECEMBER 15...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mons. Josef Denyn and Mr. W. W. Starmer, "Carillons and Carillon Playing."

Electrical Engineers, Institution of (Local Section), The University, Birmingham, 7 p.m. Mr. J. D. Morgan, "Notes on the Ignition of Explosive Gas Mixtures by Electric Sparks."

Meteorological Society, 70, Victoria-street, S.W., 7.30 p.m. 1. Mr. F. J. Brodie, "The Incidence of Bright Sunshine over the United Kingdom during the Thirty Years, 1881-1910." 2. Dr. W. Galloway, "Remarkable Cloud Phenomena." 3. Dr. J. R. Sutton, "South African Coast Temperatures."

Geological Society, Burlington House, W., 8 p.m.

Automobile Engineers, Institution of, at the Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. Mr. F. W. Lanchester, "The Cylinder Cooling of Internal-combustion Engines, more especially as concerning Automobile Practice."

THURSDAY, DECEMBER 16...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Mr. C. C. McLeod, "The Indian Jute Industry."

British Academy, in the Theatre, Burlington-Gardens, W., 5.30 p.m. (Schweich Lectures.) Mons. E. Naville, "The Text of the Old Testament." (Lecture III.)

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. Miss Marietta Pallis, "The Structure and History of Plav: the floating fen of the delta of the Danube." 2. Mr. T. A. Dymes, "On the Seed-mass and Dispersal of *Helleborus fœtidus*, Linn." 3. The General Secretary, "Sample of 'Figured Ebony,' with specimens of walking-sticks manufactured from it by Messrs. Henry Howell and Co." 4. Mr. E. S. Goodrich, "On the Reproduction of *Protodrilus*."

Chemical Society, Burlington House, W., 8.30 p.m. 1. Messrs. W. A. Haward and T. Otagawa, "The Propagation of flame in mixtures of hydrogen and air. The 'uniform movement.'" 2. Messrs. P. C. Ray and R. De, "Molecular volumes of the hyponitrites of the alkali metals and metals of the alkaline earths."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. H. G. Theaker, "Composition."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Mr. J. R. Beard, "The Design of High-pressure Distribution Systems."

Historical Society, 22, Russell-square, W.C., 5 p.m. Miss C. A. J. Skeel, "The Influence of the Writings of Sir John Fortescue."

Geographical Society, Kensington-gore, S.W., 5 p.m. Mr. W. J. H. King, "The Nature and Formation of Sand Ripples and Dunes."

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, W., 8 p.m. 1. Mr. E. A. Wraight, "Influence of Heat in Cyaniding Gold Ores." 2. Mr. A. W. Allen, "Clay: its relation to Ore Dressing and Cyaniding Operations." 3. Mr. E. Maxwell-Lefroy, "Wolframite Mining in the Tavoy District, Lower Burma."

Numismatic Society, 22, Albemarle-street, W., 6 p.m. Rev. E. A. Sydenham, "The Coinage of Nero."

FRIDAY, DECEMBER 17...Engineers and Shipbuilders, North-East Coast Institution of, Newcastle-on-Tyne, 7.30 p.m.

Mechanical Engineers, Institution of, Storey's-gate, Westminster, S.W., 6 p.m. Dr. R. Mullineux Walmsley and Mr. C. E. Larard, "Engineering Colleges and the War."

Journal of the Royal Society of Arts.

No. 3,291. VOL. LXIV.

FRIDAY, DECEMBER 17, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

CANTOR LECTURE.

On Monday afternoon, December 13th, DR. WALTER ROSENHAIN, F.R.S., delivered the third and final lecture of his course on "Optical Glass."

On the motion of the CHAIRMAN, a vote of thanks was accorded to DR. ROSENHAIN for his interesting course.

The lectures will be published in the *Journal* during the Christmas recess.

INDIAN SECTION.

Thursday afternoon, December 16th; SIR JOHN PRESCOTT HEWETT, G.C.S.I., C.I.E., in the chair. A paper on "The Indian Jute Industry" was read by MR. C. C. McLEOD, President of the London Jute Association.

The paper and discussion will be published in a subsequent number of the *Journal.*

OWEN JONES PRIZES FOR INDUSTRIAL DESIGN.

The Board of Education having decided to suspend the "National Competition," in connection with which the Owen Jones prizes have been awarded since 1878, that competition is no longer available as a basis for the award of these prizes in 1916.

The Council have therefore determined to suspend the offer of the prizes for next year, in the hope that after 1916 some suitable way may be found for carrying out the conditions of the Trust. These are that the interest on the capital amount available (£400) should be expended in prizes to "Students of Schools of Art who, in annual competition, produce the best designs for household furniture, carpets, wallpapers and hangings, damasks, chintzes, etc., regulated by the principles laid down by Owen Jones."

CENSORSHIP REGULATIONS.

The transmission of newspapers and other publications to neutral European countries has been forbidden by the Government, unless they are posted by authorised agents. The necessary authority for the postage of the Society's *Journal* has been secured, but occasional instances appear to occur in which the instructions of the Censor are not carried out by the officials, and the transmission of the *Journal* is interfered with.

Any Fellows residing abroad who find that their supply of the *Journal* has been irregular will understand the reason, and if they will communicate with the Secretary, he will be glad to supply any missing numbers.

CANTOR LECTURES ON "HOUSE BUILDING."

The Cantor Lectures on "House Building: Past and Present," by M. H. BAILLIE SCOTT, have been reprinted from the *Journal,* and the pamphlet (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C.

A full list of the Cantor and Howard Lectures, which have been published separately and are still on sale, can also be obtained on application.

JUVENILE LECTURES.

Two of the Members of the Council—Professor John Millar Thomson, LL.D., F.R.S., and Mr. James Swinburne, F.R.S.—have kindly undertaken to deliver the Juvenile Lectures this year. Professor Thomson will give the first lecture on Wednesday afternoon, January 5th, at 3 p.m., his subject being "Crystallisation." Mr. James Swinburne will give the second on Wednesday, January 12th, at 3 p.m.; his subject will be "Science of some Toys." Both lectures will be very fully illustrated with experiments.

Special tickets are required for these lectures. They can be obtained on application to the Secretary.

A sufficient number of tickets to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply for them at once.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A meeting of the Colonial Section was held on Tuesday, November 30th, 1915; Sir Henry A. Blake, G.C.M.G., in the chair.

The Chairman, in opening the meeting, said it was his pleasant duty to introduce to the audience Sir Sydney Olivier, who was to read the paper that afternoon. Sir Sydney was in Jamaica as Colonial Secretary from 1900 to 1904, and as Governor from 1907 to 1913; therefore, curiously enough, he had had just about the same length of experience of Jamaica as he (the Chairman) had. England owed her possession of Jamaica—one of her oldest island colonies—to a disaster. In 1655 Cromwell sent out an expedition for the purpose of seizing San Domingo. The expedition, however, failed in its attempt, and was repulsed by a comparatively small body of Spaniards, who drove the English back to their ships under such circumstances that, when they arrived on board, either Penn or Venables broke the sword of one of the officers over his head. A doctor who wrote an account of the matter afterwards, said that if all the men who showed dire want of courage on that day had had their swords broken over their heads there would have been but few officers left. However, the expedition went to Jamaica, whose Governor happened to be ill at the time, and conquered it. That was the beginning of the English occupation of Jamaica, and from that time to the time with which Sir Sydney Olivier's paper dealt, the island had had various vicissitudes, but had happily emerged from them in the way which the meeting would appreciate after it had heard the paper.

The paper read was—

RECENT DEVELOPMENTS IN JAMAICA: INTERNAL AND EXTERNAL.

By Sir Sydney Olivier, K.C.M.G.,
late Governor of Jamaica.

The Island of Jamaica is the largest among the West Indian colonies, not excepting in any material sense that of British Guiana, if regard be had only to the settled area of that territory. It has the largest population. It is one of the oldest settled. Trinidad, the next largest of the islands, is, like British Guiana, an acquisition of the Napoleonic war period. Jamaica is the most English of all the large colonies, except Barbados; nothing could be more English than —perhaps I ought to say nothing so English as— Barbados. But Jamaica roads and fields are more English than the Barbadian. Trinidad and British Guiana are vastly different, both because of their double European colonisation and because so large a proportion of their introduced coloured population—and that a very progressive and prosperous element—is East Indian and not negro. Finally, Jamaica is much more important and significant in relation to the problem of mixed African and white communities than Barbados, because in Jamaica most of the black population own land and are free planters and jobbing labourers; the land of Barbados is still owned almost completely by white families in estates, and most Barbadian negroes are labourers for wages either at home or in the neighbouring islands or on the Isthmus.

Consequently, for anyone to whom the problem appeals as important, "What are the capacities of the Negroid races in fusion with white civilisation, and how can such a fate as that of Hayti be evaded in a transplanted negro community?" Jamaica, which is a going community in satisfactorily stable development, where there is neither oppression nor hostility between the two races, offers a very suggestive, if not, as I myself think, the most suggestive available example for study.

Jamaica as a community has a specific character of its own—it has an established life and temperament of society. The conditions are not the same as, for instance, those of the Southern States of America. Nor are the results or the promise of progress the same. But something has grown up, something has been brought about in the two and a half centuries of British Jamaican history, which have established a community predominantly negro, which does

in fact produce upon European and American visitors the impression of having an agreeable and not unpromising social personality.

I do not propose in this paper to say anything about the associations of Jamaica in history and romance. It was once reputed a very rich and prosperous island. Its wealth at that time rested on sugar production, with, for a certain period, a considerable contribution from coffee. The days of the monopoly of the West Indies in the supply of sugar and other tropical produce to English markets passed away long ago. Their passing, together with the abolition of slavery, undermined the ancient foundation of Jamaica's prosperity. Just about thirty years ago the progressive depression in the value of cane sugar had brought Jamaica to the most difficult and critical stage in its economic history. The development of Jamaica which I propose to talk of to-day falls within these last thirty years.

The island is a long fish-shaped stretch of land with mountains throughout the whole extent of its longer axis. The highest parts of this mountainous core, which emerge through more recent strata in the eastern part of the island as the Blue Mountain Chain, in the centre as the Bull Head Ridge, and again at the west end of the island, are composed of sedimentary rocks, partly of volcanic detritus, partly of clays and shales, some slightly carboniferous, some belonging to the lower cretaceous period. These formations are broken up by intrusive waves of granite and dykes of igneous rock. The ranges emerge or are exposed through the principal formation of the island, which consists of a white deep-sea limestone analogous to the chalk in England. This formation, which, when the island was deeply submerged, must have overspread the whole of it except the Blue Mountain Range in the east of the island, has been lifted up out of the sea at the east end of the island to an elevation of about 4,000 feet, and further west forms high table-land, lying from 3,000 down to 2,000 feet up, and broken away into lower foot-hills down to sea-level. This formation has been eaten out where it was thin and overlay or embraced ancient high ground, by rain and rivers, so that there is in the centre of the island a long interior basin exactly analogous to the interior basin of the Weald of Surrey, Sussex, and Kent, with limestone ranges surrounding it as the Downs surround the Weald. There are several other small interior basins, either completely enclosed or open at one end, in other parts of the island, and the rivers from the interior core of ancient mountains flow out through the limestone, through deep gorges, exactly as the rivers of the Weald flow out through the chalk, only, because the Jamaican limestone is at once harder in texture and more soluble in rainwater than the chalk, the gorges are steeper and deeper, and often the rivers have not succeeded in cutting a gorge, but simply burrow underneath and come out in the alluvial plains round the coast. The whole of the limestone formation is weathered into ridges, hummocks, and hollows (called cockpits), and is a mass of irregular surfaces.

The alluvial plains form the third chief division of Jamaica's geological formations. The largest of them are the plains in which Kingston, the present capital, and Spanish Town, the ancient capital, are situated. These extend from Kingston to beyond Old Harbour, a distance of about forty miles, and are on an average about seven miles in width, with deep indentations.

There is another large alluvial plain in the valley of the Plantain Garden River, running out at the east end of the island and draining the valley between the Blue Mountains and the southern range of the limestone; another, westwards, in the district of Vere, where the River Minho has spread out fertile detritus and silt from the interior basin. There is another about the Black River running far inland, and another in Westmoreland. There are smaller alluvial plains of the kind at Montego Bay, and in some places along the northern coast, though generally the northern coast is much steeper than the south, and the rivers run straight from the limestone into the sea.

Now, the ancient economy of Jamaica rested mainly on the cultivation of the alluvial plains, and other parts of the older geological formation, in sugar, combined with the feeding of working cattle.

The limestone formation produced coffee, pimento, annatto, and large quantities of oranges and other fruit; it also produced very fine grass for the breeding of cattle and horse kind. These breeding properties, called pens, are run as ranches for grazing only, and the production of pimento from trees growing in the pastures. There is practically no agriculture on them. All the old sugar estates having their works in the plains had what was called their "mountain" miles away in the limestone country. The slaves had their own provision grounds there—when they were past

work they went and settled there; freed slaves bought land and settled in the mountains; many colonies were planted by missionaries and others in the same districts. The land was not worth so much for sugar cultivation as the lowlands. It was much pleasanter for habitation, and much better suited for negro husbandry. It has two notable characteristics—first, it is waterless; over three-fifths of the island there are no streams except the rivers in deep gorges or underground, because every drop of rain that falls sinks into the surface immediately; and secondly, it is constantly covered with vegetation, because, not only is the rainfall generally good, but the moisture remains diffused in the limestone as in a sponge, and rises by capillary attraction to the roots of plants. As the African method of cultivation depends on the burning down of bush to produce potash for yams and other tuberous vegetables, this kind of ground suited the freed slave very well. But in severe droughts, when the rain-water tanks give out, the population suffers much from lack of water.

When the sugar estates went out of cultivation and employment failed, the plains became even less attractive to the labouring population than formerly, and for the estates which survived labour difficulties increased, because all who could get land and maintain themselves on the limestone sought to do so. What was happening thirty years ago was that the employment for labourers formerly given on sugar and coffee estates was coming to an end, and the great majority of the peasant landowners were settled in the limestone uplands, or in other interior mountainous parts of the country, such as those round the Bull Head and on each side of the Blue Mountain Range in St. Thomas and Portland, where there were both cheap land and a water supply; in these latter parts, however, settlement was not so convenient because the roads were bad. On the whole, the limestone was the most popular formation for the reasons I have given, and because it was easy to make roads and tracks about it.

But the mountain people depended for the earning of money on coffee, whose price had lately fallen, oranges for which the market was precarious, pimento and annatto for which the market was limited, and for food on their ground provisions, grown in the African manner. It was apparent that the agriculture of peasantry could be made much more productive, and that if it were not made more productive the population might with difficulty be kept alive in a poor way; but there could be no surplus available to pay for education, medical service, or the other requirements of a progressive civilised life.

The developments in Jamaica to which I must confine my attention to-day are those of its agricultural industry, its trade with the United States and this country, and its relations with Central America as a source of labour supply for the development of the countries adjoining the Caribbean Sea. I cannot even touch on the interior educational, social and political developments which have taken place during the last thirty years.

The two principal internal changes in the productive industry of the country—and it must be remembered that agriculture is its only productive industry, and that it has no minerals, no coal, and no manufactures—have been, firstly, the development of what may be called smallholders' agriculture, with the increase of what are classed in the island's returns as minor products, and, secondly, the development of the banana trade. The external development has been associated with the growth of the banana trade as between Jamaica and the United States, and in a less degree as between Jamaica and the United Kingdom; but it has, perhaps, been even more important in an indirect manner, not commonly taken account of, that is to say, through the colonisation of Central American countries, both in the construction of the Panama Canal, very largely made by Jamaican labour, and in the development of the fruit industry in Colombia, Panama, Costa Rica, almost entirely by Jamaican labour, and further in Nicaragua and Honduras to some extent by Jamaican labour.

Most people in England have principally heard of Jamaican developments in connection with the banana, so I will deal with that topic first. Jamaica is peculiarly well fitted by latitude and climate for the growth of bananas. It is sheltered by Cuba from the cold winds from the north, which affect that island and also the northern coast of Hayti. On the other hand, its atmosphere is less heavy, hot, and sodden than that of the Central American littoral. It is now full forty years, I think, since bananas were first shipped in small quantities to America. It is about thirty years since cargoes began to be taken from time to time in small sailing vessels. It is barely twenty years since the trade became considerable enough to occupy the energies of an important American corporation, then known as the Boston Fruit

Company, now merged in the United Fruit Company of America, which controls the whole fruit trade of the Eastern States and the Caribbean Sea.

It was Captain Baker, the founder of the Boston Fruit Company, who led the way in the demonstration of the cultivation of the banana on a large scale on abandoned sugar estates. His operations had begun by contracts with small growers in Portland, where there was rich soil and abundant rainfall in the valley of the Rio Grande. Finding this source of supply not fully reliable, Captain Baker and his associates began to take up abandoned sugar plantations in the alluvial flats of that river and also in the interior valley, south of the northern limestone range at the foot of the Blue Mountains, which had been similarly cultivated in sugar. Their example was followed first by one enterprising Jamaican landowner, and then on a smaller scale by others who occupied failing or abandoned sugar estates on the clays and alluvial lands accessible from the north side of the island. This development was favoured because the north side has a better rainfall than the south side, although the stretches of easy land available are much more extensive on the south.

Extensive cultivation was next taken up in the valley of the Plantain Garden River, which I have mentioned as running out at the south-east end of the island between the Blue Mountain Ridge and the southern Limestone Range. This is a splendid tract of alluvial land in which sugar estates still survived, and where at present prices of sugar large profits ought to be being made by a central factory serving the whole valley, which is capable of irrigation. Bananas and, with prudent foresight, coconuts were largely planted here by the Boston Fruit Company, a Jamaica Company and some private owners. Unfortunately this valley is open like a funnel to the east, and all heavy winds and hurricanes come to Jamaica from the east, so that though soil and climate are very suitable, banana-planting in this part of the island has had many losses to contend with.

Further west the rainfall on the south is insufficient for bananas; but in the great plain of the Rio Cobre delta about Spanish Town a fine system of irrigation was set up forty-five years ago by Sir John Peter Grant. This had not sufficed to keep the sugar estates in that district solvent, though when I first went to Jamaica there were still a few of them struggling on. At that same time the first experiments were being made in the planting of bananas on these irrigable lands. I remember well the discussions whether fruit so grown would be firm enough to travel. To cut a long story short, since that time the whole of the irrigable land in the delta suitable for the growth of bananas has been taken up and planted, and the demand for irrigation water has more than doubled, and now reaches the limit of the supply available.

Not all the land in these plains is suitable for banana-growing, because the plant requires good drainage and an easy root run; heavy clay is unfavourable to it; but the silty loam of modern river alluvium suits it excellently, provided the supply of vegetable mould which it requires is kept up. From that time onwards the cultivation has spread into new districts, and many old sugar estates in the valley of the Great River and the Montego River and its tributaries, which flow out at the west end of the island, have been put into extensive cultivation. There has thus been a very great revival of productive cultivation on former sugar estates which had been abandoned, and this has been carried on in the face of difficulties of labour supply, which have had to be met by the importation of Indian indentured labour. Whilst the revival of agriculture on a large scale has thus been effected through the cultivation of the banana on the old sugar estates, which, as I have mentioned, had ceased to be attractive places of residence for the labouring population of the island, there has, of course, been also a great increase in the production of bananas on the holdings of the peasantry in the mountains, both on the limestone and on those tertiary and granitic interior districts which I have mentioned as exposed by the denudation of the central core of the island. The peasant has, therefore, not only been withheld from furnishing a labour supply to the larger plantations by the fact that he did not like working or living there, but also by the fact that he had a very profitable alternative in growing bananas himself, although they do not grow so well on the limestone as they do upon the loams and silts.

Further, during the period of the depression in the sugar industry and the failure of employment at good wages which that depression brought about, the Jamaican negro had found well-paid work on the Panama Canal. I believe that about 25,000 Jamaicans were in employment under the French Company when that company suspended operations. Their

discharge and the return of many of them to Jamaica was a severe reverse.

After the United States Government took up the canal the emigration thither revived, and when I was in Jamaica there were between 40,000 and 50,000 Jamaicans in the canal zone. These men were earning 3*s*. 4*d*. to 4*s*. a day, whereas in Jamaica they would have been earning 1*s*. 6*d*. or perhaps 2*s*. In the meantime, Mr. Minor Keith, the builder of the Costa Rica railroad, had been struck with the promise of the diluvial slopes along the coast of Costa Rica. Costa Rica itself is a small Spanish republic occupying a table-land 5,000 feet up in the Cordillera Mountains. The coast of the republic is a long shelf of diluvium brought down by the torrents from these mountains and meeting the sea in a fringe of swamps and lagoons.

Mr. Minor Keith began to plant bananas. The soil was virgin; the method of cultivation the simplest; the underbush of the dense forest was cleared, the large trees girdled; the banana suckers were planted immediately. The large trees were then cut down and burnt, leaving only the castiloa rubber trees standing among the young bananas. These grew so rapidly as to keep down the weeds and bush about them, and very soon were yielding enormous bunches. When I visited Central America early in 1911, the United Fruit Company, which had incorporated Mr. Keith's company and the Boston Fruit Company, had 50,000 acres of land in Costa Rica. Most of this was in bananas, some in cocoa, and some parts were used for cattle. There was not a road on the whole sea coast; the only lines of traffic were the railway lines, which were owned or leased by the United Fruit Company, and the river beds. There were 40,000 Jamaicans working on these plantations as labourers, foremen, engineers, schoolmasters, clerks, and managers; a most efficiently organised industrial republic under the absolute, though very enlightened and benevolent despotism of the United Fruit Company.

This development of banana cultivation round the coasts of Central America, with American capital and Jamaican labour, is a really very remarkable feature, more especially when it is understood that the United Fruit Company, which has created this development, practically controls the whole trade and shipping facilities of all that sea and its coasts, and, in the districts where it cultivates, is to all intents and purposes the government of the country. The great demand for Jamaican labour in the industry thus organised has removed any difficulty in disposing of the surplus labour discharged from the canal works as they have approached completion. And it is on the basis of this colonisation that another very curious development in economic history has taken place.

Probably many of my hearers will remember that about fifteen years ago the Imperial Government gave a subsidy of £20,000 a year, combined with one of the same amount from the Colonial Government, to establish a steamer service, which was to run for ten years, direct between Jamaica and England, for the purpose of developing commerce and intercourse between this country and Jamaica on the basis of the banana trade. This undertaking was most energetically and public-spiritedly promoted by Sir Alfred Jones, on behalf of the Elder Dempster Company.

It is fair to pay this tribute to Sir Alfred Jones at the outset, notwithstanding that it may be said that the enterprise was a commercial venture. As a matter of fact it was not remunerative, and the results which it established, though important, were not at all the results intended and hoped for. Speaking broadly, beyond proving that bananas could be carried and find a market in England, which was an important result, it has not done very much for the Jamaica banana trade, and it has done very little permanently for any other department of the island's commerce. It did for a time something to develop interest in Jamaica as a tourist resort, but in that connection also it must be admitted to have failed to achieve anything like what was hoped for. Sir Henry Blake was the first Governor of Jamaica who took active steps to get the island's attractions as a health resort appreciated and made available. He worked hard both by policy and by literary effort to develop this side of her capabilities. No one who knows Jamaica will question the justification of his enthusiasm or that of Sir Alfred Jones in this cause. Sir Henry Blake organised the Jamaica Exhibition of 1891, and in connection with this effort promoted the building of hotels to accommodate visitors. Sir Alfred Jones leased or bought the hotels from the Government and did his best to provide comfortable passenger steamers to carry visitors. I think what has baffled these efforts, so far as this country is concerned, is that the journey takes rather too much time out of a winter holiday for people who do not enjoy spending their time on board ship. It is also

a little expensive, and Jamaica hotel-keepers and lodging-house keepers charge a great deal, according to English ideas, for very indifferent hospitality. On the other hand, there has been, in certain seasons, a pretty large influx of American visitors, and a certain number of Canadians. The trip from New York for a winter holiday, with a fortnight in the island, is a very easy and pleasant one. A certain number of Americans have even built winter villas in Jamaica. This traffic, I think, will increase, and Sir Henry Blake's belief in its possibility be progressively justified. It is curious to remember that thirty years ago Jamaica was generally thought of in this country as having a deadly climate. It is really a peculiarly healthy place for people of regular lives.

To return, however, to the commercial aspect of Sir Alfred Jones's banana service. It started badly. The supplies of fruit from the larger estates were, to a great extent, controlled by the United Fruit Company; the men who were sent out to buy fruit and load the vessels, being new to Jamaica, did not thoroughly understand the business, and the first shipments of the fruit did not travel well. In order to save the enterprise Sir Alfred Jones entered into partnership with the United Fruit Company, whose employees were experts in the trade, and arranged for them to load the Elder Dempster steamers. This work was managed by a subsidiary company known as Elders and Fyffes. The share capital was increased, and nearly half but not quite half of the shares of the company were allotted to the United Fruit Company, Sir Alfred Jones thus maintaining control. In the autumn of 1903, when the service had been in operation for about eighteen months, a hurricane destroyed the Jamaica banana fields, and there was no Jamaica fruit for many months. In order to fill the ships, both those of the Direct Line and also additional vessels which Elders and Fyffes had built, the whole fleet was sent to Costa Rica to be loaded by the United Fruit Company from their plantations there. Thus the Jamaica banana, so reputed, became the Costa Rica banana, a somewhat larger and more insipid fruit, and the Costa Rica banana to this day it predominantly remains, because while the Costa Rica trade from the United Fruit Company's plantations has greatly increased the Jamaica trade has not increased in proportion. This is partly explained by the fact that a later development in the affairs of the Elders and Fyffes Company was brought about by the United Fruit Company acquiring additional shares in the former and thus obtaining control of its operations, which enabled them both to put pressure upon Elder Dempster and Co. in regard to rates of freight and thus diminish the profits of the Direct Line, and also to govern their relations with the planters of Jamaica in the interests of the American Corporation rather than in that of the British Colony. The Elder Dempster line has now ceased to serve Jamaica; but Elders and Fyffes have a very fine fleet of fruit steamers bringing United Fruit Company's fruit to England, principally from Costa Rica and Santa Marta in Colombia. Some Jamaica fruit, bananas, grape fruit and oranges, is carried, but in the year 1914 the total value of fruit sent from Jamaica to this country was only one-tenth of the value of the fruit sent from Jamaica to the United States, that is to say, £135,000 to this country as against £1,350,000 to the United States. This, however, I am glad to observe, is the highest amount yet reached by this trade to this country, which had in the twelve previous years since the Direct Line started only averaged £83,500 a year, little more than twice the amount of the Direct Line subsidy. So far as a market is concerned, Jamaica could sell the whole of her fruit to the United States, and the existing facilities for sending it to England do not give and never have given her a buyer competing with the United Fruit Company, as it was intended they should.

A measure of the importance of the development of the banana industry in Jamaican agriculture is given by the Blue-book returns of cultivation. In the year 1885 the agricultural returns give no statement of land planted in bananas. That does not mean that bananas were not grown, but that they were not grown separately in large arable fields as now, but mixed up with coffee, cocoa, ground provisions and other cultivation on small holdings or in small patches.

In 1895 the acreage planted is shown as 18,528. In 1905, 44,325; in 1915, 85,854—doubling itself, as you see, every ten years. It is interesting at the same time to note the figures of the cultivation of coconuts. In 1905 the acreage of coconut plantations, which are additional to great numbers of coconut trees grown scattered about the island, was 10,395. In 1905 it was 8,561, which means that in 1903 a great many coconut plantations were blown down by the hurricane. But on the whole the

hurricane of 1903 taught Jamaican planters that coconuts and cacao were a more reliable standby than bananas in windy places, and in 1915 the acreage planted in coconuts was 29,731, about three and a half times as much as ten years before. In the same period cacao or chocolate had increased from 4,628 acres to 11,088 acres, which is very much less still than it ought to be upon an island like Jamaica.

Looking back at the cane-sugar industry during the same period, the acreage in 1885 was 40,425; in 1895, 31,284; in 1905, 23,871; and in 1915, 31,727, showing a recovery, which has been due to the greater stability of the industry under the effect of the Brussels Convention, to the erection of some new central factories, and the consequent extension both of estate planting and cane farming.

It might be thought that with the present prices of sugar this industry would further revive in Jamaica, and I have no doubt that there will be shown a substantial increase in the acreage of cane cultivation so long as the present prices last. But there is no possibility in Jamaica of a re-establishment of the sugar industry in the position it once occupied as the basis of the island's economy, because the districts in which sugar can be grown and manufactured under the conditions now required for profitable sugar-making are of limited extent. As I have said, perhaps the best available area is the Plantain Garden River valley, but that is now largely planted with coconuts and bananas. The district of Vere could produce much more sugar if it were irrigated. Unfortunately one irrigation scheme has proved a failure, as the springs which fed it have never yielded a full supply since the earthquake of 1907, and another irrigation scheme now in process of development is being carried out under considerable financial difficulties. The well-watered plain of Westmoreland, favoured by rainfall, has maintained a considerable number of sugar estates in cultivation, and there is still some room for revival and extension here. There is no other large area suitable in Jamaica for sugar production on the modern system.

One change in the pastoral economy of Jamaica may be mentioned in connection with the banana industry. Jamaica used to be a horse-breeding country and produced a good deal of very good stock. The development of the banana industry has created a very brisk and paying demand for mules. The result of this demand has been progressively and now almost entirely to destroy the breeding of good horses, whilst, owing to the reduction in the number of good-sized mares that is resulting, the production of large mules is becoming more and more difficult. At the same time motor locomotion, and to some extent motor traction, are replacing buggies and waggons on the roads.

The profitable results of the development of the banana trade, the improvement of native agriculture and the large amount of money earned by Jamaica labourers on the Panama Canal and on banana plantations in Central America, have reacted in a marked degree upon internal conditions. First of all, the banana industry gave a number of small landowners, black and coloured, the opportunity of making good money. The old sugar industry had supported the planting class in comfort and had enabled them to build good houses and to take a pride in their establishments. With the decay of the sugar industry the general level of what might be called the middle-class civilisation in the island declined. The banana industry gave an opening for a revival and for the emergence of a class of well-to-do small planter, such as was supplied, to some extent, in former times by the coffee industry when coffee had a paying price. As a result, all over the country now, but especially in the prosperous banana districts of St. Mary's and Portland parishes, you can see good new houses, pretty gardens and smart turn-outs. To a certain extent, men returning from Panama with earnings swell this class. Another very noticeable feature is the improvement of peasants' houses. This has been effected principally through the improvement of local agriculture, largely the work of the agricultural societies, and also directly by what is known as the "Prize Holdings" scheme, under which the Government through the agricultural society gives prizes for the best-kept holdings, giving marks for all the desirable qualities of cultivation, live stock, buildings, fences, etc.

The policy of the Jamaica Government in regard to the economy of the peasants' life is now fairly settled and understood, so that I hope that even changes of Governors and cataclysms of finance may not permanently interfere with its development. It rests upon improvement in agricultural methods and the making and maintenance of roads, to enable produce to be brought out to market.

The fundamental idea in the agricultural education which the island requires is the substitution of mixed agriculture, employing and maintaining live stock, both for food supply

and to produce manure, in supersession of the mere growing of vegetables by the use of natural potash and humus. The principal organ of this education has been the Jamaica Agricultural Society, which was founded by Sir Henry Blake, and on whose success he may truly congratulate himself, and which has now, I believe, upwards of 100 branch societies distributed all over the island.

Jamaica, whilst it was a country of large estates, was already celebrated for the horses it bred, largely from thoroughbred imported stock. Its population being English and negro, it was a country where horse-racing was and is very popular. It was also a fine country for cattle raising, and being colonised by Englishmen and Scotsmen it knew what good beef is, and trouble had been taken to produce it. But until within the period I am speaking of the British use of live stock in agriculture had been quite outside the ideas of the peasant proprietor. He often had a horse, a mule, or a donkey, but that was for purposes of transport. He sometimes had a wretched skinny pig and a few goats or inferior fowls; but it was not until the Agricultural Society and its branches developed their work that the agricultural shows of the island began to be used as a means of encouraging good stock among the small settlers, as well as on the large pens, and the improvement of the preparation and marketing of their coffee, cocoa, and minor products.

The measure of the development of native agriculture is shown in the remarkable increase in the exports of what used to be called minor products; but this development is perhaps most remarkable, not in its material outcome, but in its social and intellectual aspects, which can best be recognised by studying the operations and activity of the Agricultural Department and the Agricultural Society now and their acceptance among the population as compared with what was the case thirty years ago.

When the Government began the work of agricultural education, by means of the activities of its instructors and through the Agricultural Society, the attitude of the negro cultivator generally towards these efforts was, for the most part, precisely the same as is the attitude of the average British farmer of to-day towards any suggestion that he might improve his methods of food production. As regards the ideas of cultivation, pruning and preparation of products which the Government sought to diffuse, they were all "buckra foolishness," and the native cultivator had no need to be taught his business. As regards a good deal of his own agriculture that was probably true. The Jamaica peasant is very skilled in knowing just where and how yams and cocoes may best be cultivated, but as regards new products and new methods he was very sceptical and conservative. In another aspect, the activities of the instructors were suspected of being merely a pretext for spying out what property the peasant had, in order that he might be taxed on it—which I am told is very much the attitude of the British farmer to-day towards any attempts on the part of the Board of Agriculture and Fisheries to improve our statistics of cultivation and stock. We are only allowed to collect them under promise of absolute secrecy.

For all agriculturists it would seem experience is the only convincing process, and I attribute the first beginnings of acceptance for the idea of improvements in agriculture in Jamaica to the stealing of the eggs of improved breeds of fowls. But now there are established, as I have said, about the island, more than 100 branch agricultural societies, which meet and discuss and take in the agricultural journal, and attend demonstrations and lectures with a real and intelligent interest. This organisation is now living and growing of its own vitality, and because it is doing this and is now a democratic and not a bureaucratic structure, it is one of the most interesting features in modern Jamaica. One of the greatest curses of Jamaican agriculture is what is called "prædial larceny"—that is to say, the stealing of growing crops and the raiding of provision grounds. Public opinion never used to be sympathetic towards the efforts of the police to deal with this evil, and nothing seemed to affect it. About fifteen years ago I had an idea as to how it might be dealt with, and about eight years later I managed to get it put into operation. Most people in any district knew who were the thieves, but they would not inform against them. I took the agricultural societies, which were then beginning to increase in popularity, as bodies of men who had an interest in cultivation and in self-protection, and I got a law passed giving any agricultural society the power to appoint certain persons who might arrest at sight any person found in possession of produce which there was reasonable suspicion that he had no right to be carrying. This would have been a dangerous power to give to the police, but it was safe to give it to representatives of the class who knew very well who were growing crops and

who were not, and the thing has worked well. I see now in the Jamaica agricultural journal frequent references to the subject of the selection of these "authorised persons" and to their activities, showing that the institution is becoming a recognised organ of mutual protection, and that the organised public opinion represented by the agricultural societies is now turned against prædial larceny. This is really a new condition of things, and I believe may do more than any of the other methods which have been advocated to repress and, as far as possible, extinguish it.

It is an unsatisfactory fact that the problem of labour supply for extensive and continuous agriculture remains very difficult in Jamaica. This results naturally from the advantages of independent peasant life, the increased interest in the peasant system of agriculture, and the fact that if a man wants to work at wages he can earn very much more at Colon or in Costa Rica. The maintenance of banana plantations or sugar estates demands a continuity of labour which it is almost impossible to obtain from creoles, and I do not see how it is ever going to be possible. Hitherto, the necessary proportion of continuous labour, for only a proportion is required, has been furnished by coolie immigration. This has been suspended for the last two years, and the prospects of its resumption seem remote.

Reviewing the foregoing brief summary, two things principally strike me. First, that there has been a revival and development of agriculture and the resulting trade in Jamaica, illustrated in the figures of exports, which in 1885 were valued at £1,484,000 and in 1915 at £2,905,000—practically a doubling—and that this development has been produced on the two different lines I have spoken of. Money has been made. Millions of pounds of profit have been made out of bananas in Jamaica and Central America, and a great deal of money has been made by her people in wages in that cultivation; but almost all of that development has been effected and almost all the profits enjoyed, not by Englishmen, but by Americans. Some Englishmen, or perhaps I should say some Scotsmen, have indeed done well, but their interests are small as compared with the interests of the United Fruit Company. I always regret that this work should have been done by Americans and not by English, and am bound to say that the reason is that, whilst the Americans had the advantage of the control of a near market, it is also the fact that they have shown greater enterprise and capacity. Secondly, there has been a considerable internal development, and this has been done by English methods of stimulus. I hope Sir Henry Blake, who can claim a great deal of the credit for such stimulus, will not insist that I shall call them Irish methods, although I am bound to say that that kind of development work has been much more effectually exhibited in Ireland than has been yet in England. The development of the banana industry has been the development of a capitalised industry by very capable direction and organisation. The development of the internal agriculture has been brought about by a stimulus to the intelligence and aspirations of the common folk of the island; the schoolmasters in the elementary schools have been brought into it; it is bound up with the popular organisation of the agricultural societies and the parish councils. It is very, very far as yet from having taken the hold of the people which it should yet do; but it has so far taken hold of them as to justify the assertion that this movement has now thoroughly established itself as a vital force in every part of the island, and is already showing substantial material results.

DISCUSSION.

The Chairman (Sir Henry A. Blake, G.C.M.G.) said the author had given a very interesting account of the development of Jamaica, especially in regard to its agricultural side. From investigations he had made, he found that in 1897, the year before he left Jamaica, there were 663,000 acres of land in cultivation, whereas in 1914 there were 940,000 acres in cultivation, an increase of 42 per cent., due to the activities of the Agricultural Board. He wished to congratulate the author on his description of Costa Rica as "a most efficiently organised industrial republic under the absolute though very enlightened and benevolent despotism of the United Fruit Company." To his mind that was a very satisfactory description of a good progressive republic, and he thought England would be all the better if it had a "benevolent despotism" to govern it. The establishment of the Agricultural Department in Jamaica had had a great deal to do with its development, but it would have been of little use if the island had not had the means of development, *i.e.*, the means of communication. After the very successful Jamaica Exhibition of 1891, there was a considerable surplus in the revenue, and the problem then arose as to whether it would be better to use that surplus to relieve taxation or to lay it by as a reserve. Many people in England thought it would be more prudent to keep it as a reserve to be utilised in the event of

bad years in the future. Personally he thought that the proper course to adopt was to spend the money in the development of the country, so that if a bad year came there would at least be a possibility of recovering from it. Therefore, during the nine years that he spent in Jamaica, 1,000 miles of roads, 22½ miles of bridges, and 197 miles of railways were built. The result of that was that fruit grown at a distance from the seashore could always be brought to the coast without being stopped by the flooding of rivers, which sometimes became impassable in a few hours and remained in that condition for many days, so that when there were no bridges, steamers coming for cargoes of bananas or other produce might be kept waiting for a long time at great expense. Sir Alfred Jones had done a great deal to develop the banana trade in Jamaica, but one of the reasons why he was only partially successful was that he had to take his bananas from small growers as well as from some of the large growers. Many of those people grew their fruit under different conditions, so that it ripened at different times, with the result that when Sir Alfred Jones obtained a cargo of it he could never be certain that some of it would not go bad before it arrived in England. It therefore had to be taken to England *viâ* New York, and some of it disposed of there. Had Sir Alfred Jones lived, it would be possible for him at the present time to obtain an entire cargo of bananas from two or three large estates, all grown under similar conditions and ripening at the same time, under which circumstances he was sure he would have made a success of Jamaica bananas as a cargo for England. A great deal had been done with regard to the educational work of the island. Educational work in Jamaica practically began in 1834. In 1666 Jane Mico, of London, widow of Sir Samuel Mico, left £1,000 to be invested for the purpose of assisting poor slaves. In about 115 years that £1,000 became £120,000, and was devoted to educational work in the West Indies. In 1834 the Mico Training College was founded in Hanover Street, Kingston, from a grant made from this fund. These premises were acquired by Government. A new college for the training of teachers was built on an excellent site and was opened in 1894. It had attached to it a fully equipped workshop and a school garden. In 1896 a technical school was established in Kingston, and there were branches of it now in every part of Jamaica. The author had shown that Jamaica had developed, and was still developing very satisfactorily. About fifty-three years ago there were 93,000 small-holders, while at the present time there were 184,000. Fifteen years ago only about 40 per cent. of the population could read and write, whereas now 55 per cent. could do so, so that education had advanced considerably in the island. He did not think the future of Jamaica depended entirely upon sugar or bananas. Sugar cultivation might be improved in the future; but he thought the Government at home might greatly assist the West Indian colonies by treating them with a little more consideration than they had hitherto shown. They had placed upon West Indian rum an additional duty of 4*d*. per gallon, which was a very serious and, in his opinion, unfair additional duty, and pressed very hardly upon the sugar industry of the islands. He had tried to introduce the cultivation of cassava, a preparation of which was called, along the South American coast, "farina"—farina being to South America what the potato was to Ireland, used by everybody at every meal. There was no part of Jamaica where it could not be grown; but it was always very difficult to get agriculturists—white or black—to start any new cultivation, and he was not very successful in his attempt. He did not think the author was correct in saying that there were no minerals in Jamaica, for there was a great deal of copper there. It had been mined at one time in the Blue Mountains, and possibly might be mined there again if the communications from the Blue Mountains were less difficult, and when last in Jamaica he had seen a large body of copper being mined in Clarendon. Continuous labour was necessary for the successful cultivation of sugar, and he was therefore sorry that the employment of coolies in Jamaica had been discontinued, for the Jamaican peasants were often busy with their own crops when they were required on the sugar plantations, therefore the labour on those plantations became intermittent. The coolies were very happy and contented in Jamaica, and took a great deal of money with them whenever they returned home. He had himself seen a man who came out as a coolie about twenty-five years ago, and who now had a large property in the west of Jamaica. It should not be forgotten what Jamaica and other West Indian colonies were doing for England with regard to the present war. The Bahamas and other small islands could not supply a sufficient number of men to form a unit of their own, so they sent their recruits to Jamaica to combine with the contingent there. English people had cause to be proud when they remembered how the whole of the British Empire had risen with one accord to declare that might should not prevail over right. When the war was over he thought the time would come when the Government at home would have to provide some means by which the different parts of the British Empire in the north and south and east and west should have some voice in reference to Imperial questions.

Sir Daniel Morris, K.C.M.G., D.C.L., expressed his appreciation of the great interest the author and the Chairman had shown in Jamaica, and the very valuable services they had rendered to that country by their speeches

on the present occasion. Jamaica was to be congratulated on having two active past Governors to lay before the people at home their views with regard to the wonderful developments that had taken place in that island. It seemed a striking fact that the revenue of Jamaica had so largely increased in recent years, that the Government was in a position to extend further the various industries and to increase grants for education and other purposes in order to uplift the whole mass of the population of the island. The author had been connected with Jamaica in various capacities. He (the speaker) went there with him in 1898 on a Royal Commission, which led to a considerable amount of interest being taken in the West Indies and also to grants being made for various industries, which had since developed to a very large extent. The author afterwards went out as Colonial Secretary, and, after the terrible earthquake in Jamaica, he was appointed Governor. From his intimate knowledge of the author's work, he thought the latter could look back with pride on the services he had rendered to the island. The Chairman also had taken a keen interest in Jamaica. He (the speaker) was in the island when Sir Henry organised, in 1891, the splendid exhibition, to which products and specimens from all parts of the West Indies were brought and exhibited for the edification and instruction of visitors from England as well as from the United States, and at the opening of which the present King, then Prince George, was present. After the exhibition he had an opportunity of discussing with Sir Henry the best way of extending knowledge of agricultural matters amongst the people of Jamaica. Later Sir Henry started the Agricultural Society, which had done an immense amount of good. With regard to the efforts of Sir Alfred Jones, one of his chief difficulties was that when, according to the terms of his contract, he wanted to buy bananas he could not get them, because nearly all the large growers were already under contract to supply their fruit to the United Fruit Company, and however much the growers might wish to support and encourage Sir Alfred Jones's efforts they could not do so. He remembered that the first paper he read about Jamaica to an English audience was so long ago as 1883, when he touched particularly upon the possibilities of agricultural development. Since then the West Indies as a whole had made great progress. The late Mr. Joseph Chamberlain, who appointed the Royal Commission of 1898, and obtained funds from Parliament for the Imperial Department of Agriculture and for steamship services, was very pleased to hear, a few weeks before he died, that the total revenue of the West Indies had nearly doubled and the total trade had increased from £16,000,000 to something like £26,000,000. In concluding his brief remarks he was sure the people of Jamaica would rejoice to read what had been said that afternoon, and would feel that they had friends at home who were prepared to do a great deal to help them.

Mr. Edward R. Davson agreed with all the remarks the Chairman had made upon the paper. He was very much struck by the author's statement that the greater part of the profits on the development of Jamaica were going into the pockets of the Americans rather than of the English. One could not feel that Jamaica was in any way to blame for that, because she naturally wished to develop her trade in the most easy and profitable direction; but, at the same time, it seemed a pity that an old English colony like Jamaica should find it more to her interest to trade with America than with England. The solution of the difficulty might be along the lines which the Chairman had indicated. It was impossible to speculate what was going to happen after the war, when economic conditions would be very different, yet he thought English people were already beginning to feel that they could not treat Jamaica, or any other colonies that had stinted and economised in order to supply money and goods to England, and that had sent their sons—white and brown and black—to take their places in the fighting line, on the same plane as those foreign countries whose one idea in the past had been hatred towards England, and whose one idea at present was to wipe Englishmen off the face of the earth. It had been his privilege on the previous day to see some of the troops of the West Indian contingent, amongst whom there were several hundred Jamaica men, and he could not help feeling—when he saw those men of Jamaica and Trinidad and British Guiana and other West Indian islands over here, not as visitors or strangers, but as men in khaki, who were prepared to do and, if necessary, die for England, and who were as much British as any British regiment—that it was impossible in the future for England to treat the countries from which those men came with the same indifference as she had sometimes treated them in the past.

Sir Evan James, K.C.I.E., C.S.I., proposed a hearty vote of thanks to the author for his most valuable and interesting paper. He himself was the great-great-grandson of one who owned a valuable sugar estate in Jamaica, which only passed from his family recently, and he had been to that island several times, both when the author and Chairman were there. Many years ago Lord Macaulay, when writing about Lord Metcalfe, who was Governor of Jamaica and afterwards Governor-General of India, said that Jamaica was the second jewel in the crown of England—India, of course, being the first. He thought Jamaica was to be congratulated on having two such Governors as the author and Chairman to stimulate its agricultural progress. Having regard to the persistent hurricanes which con-

tinually blew down bananas and cocoa-trees in Jamaica, he thought the island should trust once more to her magnificent breeds of oxen, horses, and mules. The mules especially should be of value during the present war. He was sure he would be expressing the feeling of the meeting in thanking both the author and the Chairman.

MR. BYRON BRENAN, C.M.G., seconded the resolution, which was carried unanimously.

SIR SYDNEY OLIVIER, K.C.M.G., in reply, said it had given him great pleasure to see Sir Henry Blake in the chair that afternoon. He did not think people in England quite realised what the West Indies were doing in regard to the war. As soon as war broke out nearly every young man in Jamaica who could by any possibility come away, joined the Army, either as an officer or private. The West Indies were sending home a contingent of 3,000 men and were also maintaining a reserve of 3,000, so that they now had practically 6,000 under training. The people of Jamaica were anxious to do more than that, and had sent home many gifts of money and tobacco and fruit. It was a source of pride to him to be associated personally with the West Indies, and to know what they were doing to help England in the war. He would like to make an appeal to the meeting on behalf of the West Indian Contingent Comforts Committee, of which Mr. Aspinall was the secretary, as the calls on the funds of the Committee were very much greater than had at first been expected.

FIFTH ORDINARY MEETING.

Wednesday, December 15th, 1915; W. G. McNAUGHT, Mus.Doc., F.R.A.M., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Haddon, Walter, 132, Salisbury-square, E.C.
Henderson, Lucius J., 10, Fauenil-place, New Rochelle, New York, U.S.A.
Howell, Hon. Clark, Atlanta, Georgia, U.S.A.
Lal, Lala Mohan, B.A., Gulshan Villa, Simla, India.
Phillips, J. S. M., Merchant's Bank, Pittsburgh, Pennsylvania, U.S.A.
Robbins, Rowland Richard, J.P., Holly Croft, Sipson, Middlesex.
Wooldridge, Charles L., Fulton Building, Pittsburgh, Pennsylvania, U.S.A.

The following candidates were balloted for and duly elected Fellows of the Society:—

Fakira, Meherali Mahomed, 13, Esplanade-road, Bombay, India.
Lyster, Anthony George, M.Eng., M.Inst.C.E., 2, Queen Anne's-gate, S.W.
Phelps, William Heath, J.P., Park House, 13, Park-street, Calcutta, India.
Stewart, William Arnold, Bulak Technical School, Cairo, Egypt.

THE CHAIRMAN, in introducing the authors, said the Society was privileged that evening to listen to two of the most distinguished experts living on the science of bell-making and the art of bell-playing. He had often listened with great awe to Mr. Starmer's exposition on bells, and M. Denyn was distinguished throughout the world as an artist in bell-playing—not merely as a bell-ringer but as a great artist. A good deal was heard about bell-playing in this country, but the British people had very little conception of the development of the art that had taken place in Belgium, where people came in thousands to listen to the recitals of sonatas, overtures, etc., by distinguished players. The proceedings that afternoon were very much like the play of "Hamlet" with the chief character absent, because it was, of course, impossible to mobilise within the building ten tons of bells; but no doubt the papers would lead the audience to desire to learn more upon the subject, and pursue the matter further.

The papers read were—

TECHNIQUE ET MÉCANISMES DE CARILLON.

Par JOSEF DENYN,
Carillonneur de Malines, Belgique.

Mesdames, Monsieur le Chairman, Messieurs,—

Demandé par la commission de votre honorable société à donner lecture au sujet de la technique et des mécanismes de carillon, j'ai eu un moment d'hésitation à accepter une invitation aussi flatteuse. Je crois, en effet, à la difficulté de me faire comprendre dans les explications des détails d'un instrument cependant si connu et si apprécié de nos jours. Il se pourrait aussi que le conférencier ne soit point toujours à la hauteur du technicien. Pour ces raisons j'ai à solliciter votre bienveillante indulgence.

Le jeu du carillon a été dès son origine un jeu populaire, incarnant dans nos contrées le décorum des fêtes publiques. Il consistait la plupart du temps en la performance d'airs simples et connus. Plus d'un carillonneur y excellait; il en fut même qui étonnèrent par leur montre de virtuosité. C'était, cependant, à de rares exceptions près, la limite de leur art. Il n'y avait pas de pathétique dans ce martelage du fer sur le bronze sonore. L'évolution dans ces performances a pris naissance il y a quelques quarante ans. Par suite de certains perfectionnements apportés aux détails des connections, tout en maintenant le principe du vieux système à clavier, il nous a été permis d'innover un autre genre de jeu. Pour en arriver à vous le faire comprendre, il est très utile d'établir, tout d'abord, ce qui est nécessaire à former une bonne installation; ensuite, ce qui est inhérent

à l'exécution d'une artistique performance. Dans cet ensemble nous trouvons comme facteurs: (1) la tour avec la chambre des cloches; (2) le beffroi de suspension et les cloches; (3) leur emplacement; (4) les mécanismes et connections; (5) la méthode de jeu; (6) la composition du programme de concert.

Quand une administration communale ou autre décide la restauration ou la construction d'une tour, elle en réfère à l'architecte pour la formation des plans. La tour se construit ou se restaure en conséquence. Du carillon qu'on projette, il n'est point ou peu question pour le moment. Cela se fera et s'arrangera plus tard! Quoique irrationnelle, c'est en général la manière de procéder. Grave erreur! Il arrive encore pour la restauration des tours que l'architecte tienne à son plan primitif. Or, les beffrois de construction antérieure aux carillons étaient souvent disposés en concordance d'un simple emplacement de cloche d'alarme ou de triomphe; ne possédaient point toujours les aménagements conformes aux exigences requises pour une bonne suspension de cloches ou un emplacement régulier de connections. Comme exemple, en ces derniers temps, je puis vous citer la restauration du beffroi de Gand (Belgique). Belle construction s'il en fut! On y disposait du nécessaire à parachever une installation modèle. Les cloches portaient l'inscription du roi des fondeurs du dix-septième siècle: *Hemony*. Vous détailler tous les défauts de cette installation m'entrainerait trop loin. Il suffira de vous signaler que le plancher de la chambre des cloches se trouve à trente mètres du sol, alors qu'à Malines il atteint soixante et quinze mètres de hauteur. La superficie des ouvertures de la même chambre y mesure trente-six mètres carrés; à Malines cent quatre vingts environ. Les gros bourdons sont à l'étage supérieur, là où devrait se trouver le carillon même. En vue du but à atteindre je puis affirmer que le résultat fut négatif. Avant d'établir définitivement les plans il convient donc que l'architecte visite une installation modèle; qu'il consulte le carillonneur expert. Celui-ci lui dira:—Que le carillon, selon son importance, selon les bâtiments avoisinants, selon les atours de la contrée, devra se placer de quarante à soixante-et-quinze mètres de hauteur. Que la chambre des cloches sera carrée de préférence. Si octogone ou autre, comparativement plus large (ce pour le placement conforme de toutes les connections). Qu'elle aura des ouvertures spacieuses de chaque côté de la tour (ce pour le dégagement régulier de toutes les ondes sonores). Si je vous dis spacieuses, je détermine que ces ouvertures doivent avoir, principalement en hauteur, les dimensions proportionnelles à celles du beffroi de suspension des cloches.

Le beffroi de suspension se compose d'un enchevêtrement de poutres auxquelles on attache les cloches. Il sera en bois de chêne. Le bois, à l'encontre du fer, isole le son. Aux soutènements des côtés, les poutres seront superposées et alignées dans une même direction. L'espace intermédiaire sera réglé par la dimension des cloches à y suspendre. Ce beffroi doit être construit selon les règles de l'art, trouvant sa résistance dans la solidité même de la construction; n'ayant aucune attache, nul soutien aux maçonneries de la tour. Les poutres seront de dimensions suffisantes pour maintenir, au martelage des cloches, leur complète rigidité, et assurer ainsi la prédominance de tout l'ensemble de la construction sur le poids des cloches à y suspendre. Ce beffroi sera placé au beau milieu de la chambre. Il en résulte que le tout groupé à l'intérieur laisse un espace de dégagement disponible qui *isolera* les cloches des ouvertures de la tour. On pourra m'objecter que je néglige le côté esthétique; par contre, je m'assure d'une chose capitale: la bonne *acoustique*.

Il n'entre point dans mes intentions de vous parler des cloches de carillon. Je tiens cependant à constater que pour leur fabrication l'emploi des matières premières de qualité supérieure est indispensable, la parfaite consonnance étant une condition *sine qua non* de réussite. On exclue absolument une cloche dissonante, parce qu'elle est mauvaise de nature. Dans l'ensemble elle resterait toujours une tache, à laquelle ne saurait obvier le meilleur accordage. Me basant sur les modèles des vieux fondeurs, Hemony et Van den Gheyn, je puis affirmer que l'étendue du registre d'un carillon se limite à quatre octaves. La grosse cloche pèsera approximativement de huit mille cinq cents à neuf mille kilos. Des poids supérieurs ne vous donnent plus ces tonalités claires et déterminées qui en doivent former la base. Le poids de la plus petite ne saurait être inférieur à huit ou neuf kilos sans tomber dans le domaine des sonnettes, dont la tonalité fluette et grêle manque de sonorité, de consistance, et serait de mauvais contraste.

Les cloches, ayant des attaches très rigides, seront suspendues aux poutres superposées et symétriquement alignées. L'emplacement sera en concordance de leur suite de tonalités chromatiques régulières, à commencer par les plus petites aux poutres supérieures,

L'espace réservé entre la cloche et la poutre inférieure sera suffisant pour assurer non seulement le jeu facile des battants mais aussi le placement conforme de tous les mécanismes des connections. Aux côtés du beffroi de suspension on trouvera la place nécessaire à caser quatre cloches de dimensions respectables. Tout l'ensemble de cette construction, faisant bloc homogène, sera surmonté d'une plate-forme, à moins que les dispositions spéciales de la tour ne vous en dispensent. Ce faisant, vous concentrez dans le jeu les effets sonores; vous groupez les différentes tonalités avant d'obtenir le dégagement parfait de l'accord harmonique: lequel, par ses vibrations fusionnées, charmera l'ouïe des auditeurs. Pour les grands carillons il reste cependant à placer les bourdons. En général, cela n'inquiète guère l'architecte ou le fondeur de cloches, qui s'empresseront d'utiliser la place disponible réservée au dégagement des ondes sonores. Le carillonneur moderne, ayant comme objectif l'effet intense à obtenir dans les performances artistiques, ne sera point du même avis.

En effet, n'ayant plus le choix de la place, il faudrait forcément suspendre les grosses cloches autour de l'ensemble du carillon. Il en résulte: (*a*) un entassement de la chambre des cloches; (*b*) un placement arbitraire et irrégulier des connections; (*c*) une suspension de cloches coudoyant ou masquant même les ouvertures. Or, placés en privilégiés, ces bourdons domineront, par l'ampleur de leur sonorité déjà supérieure aux autres cloches. L'artiste, malgré une impeccable exécution, ne saurait produire dans son jeu la fusion complète de toutes les tonalités. J'en fais ici un grief au beau carillon de Bruges. La supériorité de celui de Malines tient de son emplacement modèle en cloches et mécanismes. On y trouve les six basses placées à un étage inférieur. Des abat-sons ferment les ouvertures, en font une chambre close et mystérieuse. La sonorité y est tempérée—se mêle en accompagnement discret à l'ensemble harmonique. Les cloches étant placées à l'intérieur de la tour, en rangées superposées et symétriques, laissent toute la place nécessaire à l'adaptation régulière du mécanisme à cylindre avec les connections du jeu des marteaux d'un côté; du mécanisme à manuel avec les communications du jeu des battants de l'autre.

Le mécanisme du cylindre se place généralement à l'étage immédiatement inférieur à la chambre des cloches. Il se compose d'un tambour dont la matière est de bronze, laiton ou fer. Il est percé d'innombrables trous, ronds ou carrés. On y place les tacquets à vis, fixés par un écrou à l'intérieur du cylindre. Ces tacquets correspondent à des claviers en acier auxquels sont attachées les connections en fil de fer galvanisé. Au moyen d'une équerre de transmission le fil est mené au marteau, en repos sur un ressort d'acier—celui-ci fixé et ajusté devant la cloche. Dans sa rotation le cylindre, armé de tacquets, bascule les leviers. Ceux-ci soulèvent les marteaux, qui frappent extérieurement la cloche à son rebord inférieur. Chaque cloche, selon son rôle d'importance, possède un, deux, trois ou quatre marteaux. Une répétition précipitée de la note, dans une même mesure, exige l'emploi de différents marteaux. Le rôle d'importance d'une cloche varie selon la mélodie et la tonalité de base. A cet effet, il y a des installations où les cloches sont munies en surplus de marteaux de réserve, appelés "de rechange." Chaque rangée de trous au cylindre, prise dans le sens horizontal, indique la totalité des marteaux actionnés. Dans le sens de la circonférence le nombre de trous correspond à celui des mesures. Ainsi le cylindre en bronze du carillon de Malines actionne nonante marteaux, compte cent et quatre vingts mesures. Il est percé de $90 \times 180 = 16{,}200$ trous carrés. Le plus grand cylindre connu est celui du carillon de Bruges. Dans l'impossibilité d'émettre une estimation exacte, je puis néanmoins affirmer que le nombre de trous dépasse les trente mille. L'espace qui sépare chaque rangée est uniforme. Sur une matrice spéciale on divise cet espace en seize ou vingt-quatre parts égales, à l'effet d'ajuster les différents tacquets. On emploie ces divisions *ad libitum* selon le mouvement lent ou accéléré que l'on veut imprimer à la mélodie. Au mécanisme automatique du carillon d'Utrecht (Hollande) j'ai constaté récemment l'emploi d'une note unique, variable dans ses divisions, dont l'ajustage se fait par suite d'une ingénieuse adaptation d'un mécanisme spécial, déplaçant le cylindre. Je félicitai l'auteur pour sa trouvaille tout en émettant des doutes sur le côté pratique de la nouvelle invention. Adapter les airs au cylindre est une opération vulgaire à la portée d'un chacun. Cela s'apprend très facilement. Dans la musique écrite on marque les notes du chiffre correspondant à la division du tacquet qu'on place. Dans le sens de la largeur du cylindre on appose au préalable une latte indiquant le nombre des marteaux de chaque cloche, composant l'ensemble actionné. L'arrangement de la musique est chose capitale. Le carillonneur

peut y prouver plus ou moins de savoir. Enfin, un volant régulateur, mis en mouvement par le contact de trois arbres de transmission munis de rouages, assure au cylindre son mouvement régulier et uniforme. Un poids moteur actionne automatiquement l'ensemble du mécanisme. Ce jeu du marteau sur la cloche peut produire un effet agréable, mais ne saurait donner aucune expression à la performance. Elle reste toujours incolore.

Tel n'est point le cas du mécanisme à manuel pour carillonneur. Tout en conservant l'ancien et rudimentaire système, nous avons réussi à perfectionner cet instrument à tel point qu'il nous est loisible, en maintenant toute la virtuosité d'en temps, d'interpréter les mélodies simples de la façon la plus expressive. Je viens de vous dire que le mécanisme à cylindre actionne les marteaux à l'extérieur de la cloche. Notez que le carillonneur manipule les battants suspendus à l'intérieur. L'instrument se place devant les cloches, au même étage, se joue du poing. Le mécanisme à manuel se compose de deux soutènements de côté, en bois de chêne ; reliés dans leurs parties supérieures par deux encadrements dans lesquels se placent les touches en bois. L'encadrement de devant sera en fer. Les parties inférieures sont de même munies de deux encadrements pour le jeu des pédales. L'étendue du registre des pédales pour grands carillons se limite ordinairement de la basse fondamentale à la quarte de la deuxième octave. Une série de barres de fer pivotantes à équerres droites, placée à l'intérieur du manuel, relie les touches aux pédales. Les connections primitives, comme on les trouve encore adaptées à la plupart des instruments campanaires des Pays-Bas, se composaient simplement d'un fil de fer, muni d'un tendeur à vis ; pour former l'angle intermédiaire on usait d'un anneau centralisant le fil de la touche, celui du battant, enfin un troisième attaché à un point quelconque pour assurer l'équilibre de l'ensemble. La connection prenait fin au battant. Ce système présentait le défaut de produire trop d'élasticité, un réglage insuffisant de la touche, laissait le battant à ballotter de façon par trop nonchalante. Pour y obvier, nous construisîmes tout un échafaudage de barres de fer pivotantes, placé devant le beffroi de suspension, se développant en étendue proportionnelle à celle des battants de cloches à actionner. Chaque barre est munie d'une équerre droite, placée à fil de plomb au-dessus de la touche du manuel ; d'une équerre recourbée qui mène le fil devant le battant en position normale. De cette façon les connections de la touche au battant passent par un seul angle droit—rigide—absolument dépourvu d'élasticité. Le tendeur à vis, suspendu précédemment au fil, est remplacé par une plaque à vis, fixée dans la touche même, et en permet un parfait réglage. Pour assurer la flexibilité des connections on coupe les fils d'œuillets à espaces déterminés. Pour tenir leur rigidité et éviter ainsi les ballottements encombrants on les enclave à distance. A la partie inférieure du battant de la cloche on applique un œuillet à vis où se concentrent les quatre connections nécessaires au parachèvement de l'installation. D'abord le fil de l'équerre au battant, dont la disposition est symétrique pour toutes les cloches régulièrement placées. Ensuite les fils emprisonnant l'œuillet de droite et de gauche ; établissant une liaison entre battants ; réglant les mouvements de balance tout en assurant la liberté nécessaire pour la parfaite manipulation. Enfin le fil mené à un ressort de rappel, placé derrière le battant. Ce ressort de rappel, qui marque le point terminus de la connection, est une pièce de détail d'une importance capitale. Il joue le rôle de force négative combattant l'effort positif créé par le coup de poing du carillonneur. Placé entre ces deux tractions opposées, ce morceau de fer, martelant le bronze sonore, s'anime alors. L'artiste parvient à le maîtriser, à le dompter, à le vivifier même. Tout l'ensemble du mécanisme des connections est bien simple et n'exige point de connaissances spéciales pour sa fabrication. Seulement la position exacte de toutes les pièces de détails doit être judicieusement comprise ; le placement bien ordonné. Cela nous permet alors d'atteindre une expression intensive dans l'interprétation, grâce à la nouvelle méthode de jeu.

Le jeu primitif consistait dans la performance d'une simple mélodie ou dans l'exécution d'une série d'arpèges et d'exercices techniques. L'art du carillonneur atteignait un rythme plus ou moins cadencé. Certes, les plus habiles montraient des qualités hautement appréciables, mais qui en somme se limitaient à une virtuosité d'acrobate. Le jeu, quelquefois agréable dans sa naïveté, restait néanmoins toujours incolore. Les différentes valeurs de notes s'interprétaient simplement du même coup de cloche suivi d'une pause d'attente adéquate. Que pouvait-on faire ? . . . Parmi les perfectionnements apportés à l'ancien système se trouve la plaque à vis adaptée à la touche, qui nous laisse la faculté d'un minutieux ajustage. Les perfectionnements de détails apportés au mécanisme des

connections nous permettent de nuancer à volonté; cela d'une manière parfaite. Nous essayâmes le jeu comparé—c'est à dire, nous rendîmes la mélodie en octave, en tierce, en sixte, ou par accompagnement de simple note de passage. Cet emploi de différentes notes pour rendre la mélodie nous permit d'exécuter les trilles. Or les trilles parfaites, traversant l'espace, se dépouillent de toute rudesse; se fusionnent complètement; arrivent à l'ouïe des auditeurs donnant l'impression et le charme du chant soutenu. Partant, le problème de la valeur effective et réelle de la note fut résolu. C'est là tout le secret du jeu moderne. En ce qui concerne les grands carillons à quatre octaves, qui possèdent les basses profondes, l'effet le plus intense s'obtient au moyen du contraste créé par l'emploi du jeu comparé des deux extrémités. Pas de médium. L'accord harmonique soutenu des cloches au son cristallin bien trillé, en accompagnement de simple bourdon, est vraiment impressionnant. Tous les carillonneurs ne réussissent point dans ce genre de performance. Un jeu nerveux et concentré, s'alliant à l'ajustage parfait de la touche, est absolument requis. Une connaissance profonde de l'instrument, dans tous ses détails, est nécessaire. L'artiste étudiera toutes ses cloches et en caressera les privilégiées. Par exemple: il vous jouera au carillon de Malines la marche funèbre de Chopin en *sol mineur*, à Bruges et Anvers en *ré*; une Sixième Sonate de Valentin Nicolaï en *si* ♭, ailleurs en *ut majeur*. Tout cela dépendra de la tonalité de base, de la qualité des cloches, des dispositions générales de l'ensemble. Il évitera l'emploi de telle tonalité. Il arrangera la musique en conséquence, pour ne point faire ressortir les défauts inhérents à tout carillon.

La composition d'un programme de concert demande beaucoup de soins. L'assistance est très variée: intellectuels, artistes, musiciens, gens du peuple—instruits ou non éduqués! Il faut en venir à contenter tout ce monde. Pour un auditoire nouveau on jouera de préférence des airs connus et populaires; des mélodies simples à conception facile. Il m'arriva en 1891 de jouer du carillon à Aberdeen en Écosse. Je présentai au public un programme de concert qui m'aurait valu en Belgique l'approbation générale. L'Écossais resta froid. Au premier moment j'en fus quelque peu désappointé. Le mystère fut vite éclairci cependant. J'insérai au programme d'un deuxième concert une série d'hymnes religieux très en vogue. Les milliers de voix d'un nombreux public accompagnèrent en chœur. Le succès complet couronna mes efforts. Le carillonneur éveille l'attention du public initié en entamant un prélude à séries de brillants arpèges, immédiatement suivi d'une performance qui nécessite une grande virtuosité. L'auditoire est conquis d'emblée. Il interprétera ensuite, en contraste, une suite de mélodies au jeu simple et charmant, quoique toujours profond et très soigné dans l'interprétation. Une musique classique, variante nécessaire, divisera nettement le programme et aura l'avantage de plaire aux musiciens et aux intellectuels. La deuxième partie se composera d'un autre genre de mélodies, entrecoupées de morceaux caractéristiques allant toujours en gradation pour arriver à une exécution finale ou le carillonneur, usant de tous ses moyens, de toutes ses facultés, atteindra un maximum de nuances, qui laissera le public abasourdi sous l'effet de l'impression la plus profonde.

Le carillonneur doit, en général, jouer de mémoire. Une lecture suivie de la musique le distrait de son clavier, l'empêche de se donner librement à la manipulation de la touche. Toute interprétation doit porter un cachet personnel. Ces prédispositions spéciales doivent être doublées d'initiative et de développement intellectuel. Il en manque malheureusement à beaucoup de carillonneurs, et par le fait plus d'un doit forcément négliger le côté artistique.

Pour obvier à cette situation on songea à fonder une école nationale de carillon. Les plans en furent dressés par mon *alter ego*, M. Édouard De Keyzer, de Malines, en collaboration avec notre ami Henry De Coster. Outre le cours de technique on y enseignerait l'esthétique; l'histoire de la cloche; l'harmonie spéciale et simplifiée à y adapter. Les plus hautes notabilités sociales, religieuses et administratives, donnèrent leur adhésion. L'État, la Province, la ville de Malines, un comité de généreux donateurs voulurent assurer la stabilité de l'institution nouvelle, quand la présente guerre vint reculer la réalisation de nos projets à une date indéterminée.

Les concerts du soir à Malines datent de 1892. Ils se donnent les lundis aux mois de juin, juillet, août et septembre, et furent institués grâce à l'initiative de feu M. l'Échevin Théodore De Coster de regrettée mémoire. Au début, la tâche fut quelque peu ingrate devant l'indifférence quasi générale. Quelques rares me comprirent; ils suivirent assidûment les performances. A cette époque, ils étaient les seuls visiteurs de la "ruelle sans fin," si réputée de nos jours. A

la clôture de chaque saison, ces quelques amis de l'art — professeurs, peintres, sculpteurs, musiciens—tenaient à me serrer la main en signe de gratitude; m'encourageaient à persévérer dans le travail difficile que j'avais entrepris. Je trouvai une aide précieuse dans la collaboration active et désintéressée d'un homme de talent, M. Édouard De Keyzer, qui se fit le manager du carillonneur. Il organisa la propagande, publiant les programmes périodiques sous forme de petits livrets qu'illustrèrent des artistes de renom, parmi lesquels j'aime à rendre hommage à mon ami, le peintre malinois Albert Geudens. L'intérêt grandissait. Le concert extraordinaire donné en l'honneur des membres du Congrès Néerlandais siégeant à Bruxelles en 1906, les concours pour carillonneurs organisés sous les auspices de l'État et de l'Administration communale, finirent par secouer la torpeur publique Les étrangers affluèrent et l'assistance toujours plus nombreuse devint cosmopolite. Les lundis de chaque semaine, arrivèrent en files interminables de pèlerins, ces fervents de l'art nouveau se rendant aux emplacements privilégiés, s'installant en plein air au risque d'encombrer la circulation publique. L'autorité intéressée dut prendre des mesures spéciales pour réglementer et suspendre même en certains rayons tout traffic durant l'heure du concert. Sur la proposition de feu M. Franz Van Kuyck, alors échevin des beaux arts, la ville d'Anvers organisa avec succès des concerts de ce genre. Gand, Bruges, Mons, Louvain, d'autres villes encore, restaurèrent leur carillon et s'en furent à l'exemple de Malines et d'Anvers. Quand au soir d'une journée estivale, fatigué du labeur quotidien, il vous est donné d'admirer les beautés de la nature—la tour géante se dressant en pénombre sur un ciel étoilé—à travers le vert feuillage le rayon glissant d'une lune argentée—ah! dans pareil cadre, le chant de la cloche incarne la plus merveilleuse féerie que l'oreille humaine puisse entendre, un régal d'art que la presse belge ne craignit point d'affirmer unique au monde. Le juriste éminent et universellement connu, Edmond Picard, proclama l'effet merveilleux d'émotion, de pénétration et de grâce. La tour, dit-il, devient un être vivant, ouvrant ses puissantes lèvres, remuant sa lourde langue de métal; dilatant ou resserrant son gosier de granit. Tout est force, sonorité ou souplesse. M. Auguste Michotte, de Bruxelles, sous l'impression du dernier concert donné au mois de juillet 1910, s'exprime ainsi:

"A mesure que se déroule le programme, l'impression devient plus haute, plus grave, plus profonde, et quand pour finir le carillonneur joue son prélude, une sorte de rêverie inspirée, lorsque les dernières modulations s'éteignent dans un pianissimo impalpable, s'évanouissant et s'exaltant dans un murmure divin, je dis qu'il n'y a personne dans l'auditoire qui n'ait éprouvé le grand frisson sacré, celui qui fait trembler la voix et qui mouille les yeux. . . ."

Cher peuple anglais, je vous le souhaite, ce carillon qui éduque le peuple et ennoblit la race!

CARILLONS AND CHIMES.

By William Wooding Starmer, F.R.A.M.

This afternoon it is my great pleasure to co-operate with my old friend, Josef Denyn, on a subject which to both of us is of the greatest importance and of the greatest interest; consequently, instead of speaking to you on a particular aspect of the subject which might be completely and separately treated, I propose to supplement some of the statements M. Denyn has made, so that fuller appreciation may be possible of the special points the time at my disposal will permit me to deal with.

Lantern-slides which I have had specially made for the purpose will, I trust, elucidate some things which are very difficult to explain in words.

First I will deal with the magnificent tower of Malines, which is 320 ft. high and the finest of its kind in the world. Although not completed according to the original design, which provided a spire (the total height of the tower and spire being greater than that of any similar structure in Europe), I think it will be readily admitted that the tower, as it stands, gains very much artistically by its incompletion. It is perfectly designed for the good disposition of the carillon, and the nature of the surrounding country greatly helps the effect of the bell music and enables the bells to be heard over an extensive area. The height of the bells in the tower, too, is an important factor—the lowest being quite 200 ft. from the ground. Then there are no obstructions to prevent the sound from travelling to the furthest possible limit in any direction. In passing, it may be stated that a carillon should never be less than 100 ft. high. Of course, there are many considerations which might modify such requirements, but I doubt whether, under any circumstances, a good result could be otherwise obtained. There must be no immediate reflection of sound about the tower, and there must be no hindrance whatever to the sound travelling in all directions equally well.

The beautiful effects obtained by M. Denyn from his wonderful instrument are made possible by the excellence of the bells, the good suspension, and the satisfactory height at which they are placed.

Next the bells may be dealt with. There are forty-five—the reputed weight of the largest being $8\frac{3}{4}$ tons, while the reputed weight of the whole of the bells is $33\frac{1}{2}$ tons. The oldest bell is dated 1480, twenty-six being cast by the famous Pierre Hemony in 1674. The compass is four octaves, less one note. Many of the bells are of great antiquarian interest, and the ornamentation in some instances is very fine.

The uses of bells in this country and the special requirements of bells when made and hung for the purpose of change-ringing, have caused variations in shape and thickness which have proved to be unfavourable to the bell, when considered as a musical instrument.

Many of our bells are poor in tone and inaccurate as to tune. Change-ringing is responsible for the alteration of shape—the shortening of the body—so that the series of harmonic tones has been completely upset, to the detriment of both tone and tune.

In times gone by, instead of improving the method of bell-hanging and the proper adjustment of the balance of the bell, our forefathers indiscriminately treated the bell itself and altered it in such a way as to impair its symmetry, in order that greater ease in ringing might be attained. Now, however, this problem presents no difficulties which cannot be overcome.

A consideration of the greatest importance is the difference in the construction scale in making bells for carillon use and for change-ringing. The following table will show where these differences occur :—

	For Carillons. Cwts.	Qrs		For Change-Ringing. Cwts.	Qrs.
1	1	2	G	6	0
2	2	0	F	6	1
3	2	2	E	6	2
4	3	2	D	7	1
5	5	0	C	8	0
6	6	0	B	9	0
7	8	2	A	11	0
8	11	3	G	13	0
9	16	0	F	17	0
10	20	2	E	20	2
11	28	0	D	28	0
12	40	0	C (Middle C)	40	0

The reason of the heavier weights in the smaller bells of the change-ringing scale is to prevent them being swamped by the larger ones, and, for the purpose, increased thickness is an absolute necessity. This upsets the harmonic tones more or less, and although the most important ones can be satisfactorily dealt with, at times no tuning can completely rectify the subordinates.

Then, of course, the difference between the methods employed in sounding the bell has to be taken into account. In the carillon the clapper strikes the bell (hung "dead" or "fixed") from a very short distance; consequently no great volume of tone is produced. In change-ringing the bell completes a circle for each blow of the clapper, which thus hits the bell with great force.

Taking these things into consideration, it is difficult to make any true comparison between the use of English bells cast on a different scale and operated upon in an entirely different manner, and Continental bells made for carillon use, automatic or otherwise.

There is not much to say with reference to bell sounds produced by a mathematical formula in which musical considerations have hitherto played only a small part, although in recent years much attention has been given by composers of peals to the elimination—as far as possible—of changes containing unmusical cadences. It is not possible, however, to get rid of the unsatisfactory musical effect of the finals of some changes.

Far be it that change-ringing should in any way be discouraged, but music played from the clavier raises the bell to a much higher plane and makes the musical expression almost as great in its possibilities as in pianoforte playing. It is difficult to realise how such effects can be obtained by means of a mechanism that is of comparatively rude construction. There is much room for improvement in the action-work connecting the clavier with the bells, but there is not the slightest difficulty in accomplishing this.

It is probable that in the near future the action-work will be pneumatic, electric, or both—ensuring such control of expression that the player can use a keyboard identical with that of the pianoforte, thus avoiding the great physical exertion which is now often necessary. With such an action the finger will do what is now done by the hand, and the playing of the pedal will be no more laborious than is the case with the modern organ.

The clavier is arranged on the same principle as the manuals of an organ. The keys are made of oak. They are round, being about $\frac{3}{4}$ in. in

diameter. There are two rows of them, the upper representing the black notes of the ordinary keyboard, projecting 3½ in., the lower, corresponding to the white ones and projecting 6½ in. The pedals are one octave or more in compass. The pedal board is a necessity, because the larger bells require much more force to bring out their tone. The clappers are consequently much heavier, and demand a considerable expenditure of energy to move them. The pedal clavier also greatly increases the resources of the instrument, and permits the music to be played in three or more parts.

The keys are struck with the closed hand, the little finger being protected with a leather covering to prevent injury when playing. As the leverage of the key has to move the weight of the clapper, which in large bells is very considerable, and as the amount of tone produced depends entirely upon the amount of force with which the key is struck, it will easily be understood that carillon playing requires a great deal of strength as well as celerity and skill.

The connection between the key and the bell clapper is exactly the same in principle as the tracker action used in organs, iron levers, squares and wires being used in the place of the wooden materials of organ building. On the clappers of the smaller bells springs are fixed to bring them back into their original position quickly after striking. In the larger bells the clappers are too heavy for this arrangement. They have a simple appliance consisting of a chain which is attached to the "flight" of the clapper and passed over a pulley. A weight is fixed to the other end of the chain sufficiently heavy to bring the clapper within a very short distance of the sound-bow of the bell, so that the key has only to upset the balance between the weight and the clapper.

The mechanism connected with each key is fitted with an adjustable screw-plate, or other device, by which the tension can be regulated to a very great nicety and the touch adapted to the requirements of the player.

The bulk of the playing is done on the smaller bells, with only occasional use of the larger ones. The reasons why this should be so are:—

(1) The small bells are more easily manipulated;

(2) The effect of chords is much more satisfactory than on the large bells, owing to the fact that in the latter the harmonic tones are very prominent and frequently interfere with each other when sounded together in a disagreeable manner.

This is not the case with the smaller bells when used in combination, as their harmonic tones are too high in the scale of sounds to inconvenience the ear.

Concerning the chime apparatus there is much to be said. With us melody only is played, and rightly, too, for, as a rule, our bells are much heavier than those on the Continent, which are used for two, three, or four-part harmony. Heavy bells, especially when the notes are near together, would be unbearable in combination, because their harmonic tones would greatly interfere with each other. This interference would be greatly accentuated in any extended compass, because until recent years all sets of bells in this country—whether diatonic or chromatic—have been on the ringing scale, which means that they are thicker and heavier than they should be for carillon use. Perhaps this has been unavoidable, as in several instances a specified number of bells in the scale have been hung for change-ringing. It is well to state that it is most undesirable to make bells on the ringing scale for carillon use, and it is equally undesirable to use bells made on the carillon scale for ringing purposes. The demands in both instances differ widely, and the bells cannot be made to serve two purposes satisfactorily or equally well. Until recently this has not been properly understood in England. The late Lord Grimthorpe is responsible for much of the trouble relating to thick bells. He insisted on having all bells over which he had any jurisdiction made on an abnormally thick scale. Experience has shown that on this point he was wrong, although his crusade may have prevented many bells from being made too thin.

Our ancient chime machinery is very simple, and consists of a weight-driven barrel, sometimes as large as three feet in diameter, generally made of wood, into which pins are fixed on exactly the same principle as in the barrel of a musical box.

The pins in the chime barrel pulled down levers which lifted the hammers with which they were connected by wires, and released them so that in their descent they fell upon and struck the bell from the outside.

In passing, I might mention that in mechanical chimes the hammers always strike the bell from the outside.

Of course, in such a machine the barrel had to do all the work. It was satisfactory so long as the requirement was merely the playing of a regular succession of notes of equal value at a moderate speed—a simple hymn tune, or the

like. But as there are very few melodies of real interest which come within these limits, particularly as regards secular tunes, more elaborate airs consisting of unequal notes, mixed long and short note values, groups of short notes in quick succession, etc., were set on the chime barrel. Such demands had the effect of obliterating everything in the shape of correct time in the rendering of the music, because the chime barrel with the same motive power had to play, perhaps, four notes in the same time as one which preceded the group of four and two which followed, *e.g.* "Rule, Britannia!"

As you can well understand, these unequal demands made the speed of the barrel very irregular, with the result that one bar was played at a quicker or slower time than another. This made the musical effects of many chimes very unsatisfactory, and, in not a few instances, quite grotesque. The fault was in trying to make the mechanism do what it was incapable of, and for a time, no doubt, this tended to mar the popularity chimes had gained.

About fifty years ago improvements in chime mechanism were made by Messrs. Lund and Blockley. The general principle was good, but certain parts of the machine were too weak to bear the strain of the very heavy driving weight used.

Other improvements were made by Messrs. Gillett, of Croydon, who erected their first carillon machine at Boston parish church in 1868. The particular advantage of their machine is that it divides up the mechanical operations. A separate movement is fitted to raise the hammer-levers into action immediately after they have fallen and struck the bells. When raised into position they are prevented from falling by a spring trigger which can be released by the slightest touch. The only work the chime barrel has to do is to release the triggers, so that the demand on the barrel is reduced to a minimum.

The most recent invention in our carillon machinery has been made by Messrs. Smith and Sons, of Derby. It differs from Messrs. Gillett's machine principally in the subdivision of the driving power.

Each hammer, or set of hammers, has its own special mechanism driven by a separate weight instead of the motive power required being derived from one source, as is the case with other machines. Consequently the weights are so adjusted that the driving power is at all times adequate for the proper working of the hammers, individually and collectively. I mean that, however great the demand is, it never makes the smallest difference in the efficient working of all the parts, thus securing perfect time in the playing of the tunes.

This is a decided advance, and with such a mechanism almost anything can be played, although it is undesirable to set very quick tunes on the chime barrel.

At Malines, in some instances, there are as many as four hammers to each bell, so as to ensure the quick repetition of the note when required. The connections there between the chime-machine and the hammers are made by means of wires, squares, etc., just as in our own chimes. These vary from fifteen to forty feet in length. Although the connections are in appearance somewhat clumsy, they require a very nice adjustment.

The chime-barrel is made of gun-metal, with two rim cogs and a centre guiding cog. It was cast in 1733, completed in 1734, and is 5 ft. 3 in. in diameter. The driving weight is 1 ton 6½ cwt., being about 4 cwt. in excess of that which is absolutely necessary for the purpose. The chain to which the weight is attached is over 90 ft. long, and is wound round an oak drum fixed on the axle of the chime barrel, so that the weight-force exerted is direct—*i.e.*, there is no gearing.

The chimes are set twice a year—at Easter and in October—and as the barrel is a permanent part of the mechanism the chimes can only be altered by a rearrangement of the studs. This takes about four days to do. There are no interchangeable barrels such as we have in England —a disadvantage; but against this must be set the greater accuracy of the rendering of the music obtained by using a large barrel, and by providing such generous driving power.

The Malines chimes play no less than eight times during the hour: a short flourish at each half quarter, a short piece at the quarter before and after each hour, a longer piece at the half hour, and at the hour a piece of still greater length. The hour is struck as in England, but the hour to come is announced after the half hour on a smaller bell than that used for the hour strike.

In our own country many of the disgusting exhibitions we are forced to listen to, and which in many instances set people against chimes, are the result of gross carelessness and inattention to the proper upkeep of the chime mechanism. In many instances, when chimes are put in a church and set going, there seems to be a general idea that they will work for the next

century without any attention whatever. If mechanical chimes are to be successful they require very frequent attention and regulation. The chimes at Malines could never be so satisfactory if it were not for the fact that they are under the constant care of an expert specially employed to look after them, and who almost lives in the tower.

It is not so long ago that our bells and belfries were allowed to get into a very disgraceful state. Now, happily, this is utterly changed; but I regret to say that chimes, generally speaking, are grossly neglected.

The adjustment of the hammer connections and the regulation of the different parts require just as much care and attention as the action of a pianoforte, to ensure the most satisfactory results and to prevent the extravagant wear and tear of the mechanism caused by neglect.

In conclusion, I cannot do better than repeat what I have already said on many occasions when lecturing on this subject. The carillon with clavier is the finest musical instrument in existence for educating the people in and cultivating their love for folk-songs and in teaching them the great melodies of their fatherland; for the music best suited to the carillon—excepting music specially written for the instrument—includes the folk music which has successfully stood the test of time.

In reply to questions asked by members of the audience, MR. STARMER said the bells were struck by iron clappers. The first carillon in England was put up at Cattistock, in Dorsetshire, in the church of Mr. Stickland, who was present that evening, and he believed it consisted of thirty-six bells, three octaves in compass. There was also a carillon of thirty-three bells at Bournville, a carillon at Liverpool, in Messrs. Taylors' foundry, and a carillon of thirty-seven bells at Aberdeen. He was sorry to say the last was out of gear, and it was now impossible to play it. The Scotsmen, he believed, thought it would be rather loud, and when it was opened they went to the neighbouring hills about Aberdeen, but could not hear it; and he did not think they had taken very much interest in it since. There was one question which he was very pleased indeed to be able to answer. As far as he could gather from the most authentic information it was possible to obtain, a communication which was probably the latest that had been received from Malines, the tower was practically undamaged and the bells were intact. Anyone desiring further particulars on any points mentioned in the paper would find the whole subject of carillons dealt with and illustrated in the *Musical Times* of April and June this year; the articles mentioned all the carillons in England, and gave a scale of the weights of bells, etc. With regard to the complaints frequently heard of inharmonious bells and disjointed playing, if it were chime-playing it would be the mechanism that was at fault, but if the bells were played from a keyboard or chiming-machine the defect would be due to the player. He hoped that when they reached home the audience would attempt to play "God Save the King" on the eight notes of the scale, as it would teach them what some people had to put up with. He had heard it played, and as the players had not the leading note in the right part of the scale they took it up several notes. It reminded one of Mendelssohn's scoring in one of the songs in the "Midsummer Night's Dream." With regard to tuning, if the bells were tuned on a good system—and there was only one system, the right one—there could be no disagreeable effect from hearing bells in succession. Most of the peals of bells in England, especially those made by itinerant bell-founders, were exactly what one would expect them to be. If a bell had one series of harmonic terms and the next one had something quite different, it was impossible to get any musical sequence at all. If the bells were tuned as they should be, and as all good bells of the master bell-founders, such as Hemony, were tuned, with so many perfect octaves, no one would have any difficulty whatever in listening to bells, or even in being able to judge whether they were or were not in tune. With regard to tubular bells, he did not think any *carillonneur* would deal with them; at any rate he had never dared ask a *carillonneur* that question.

On the motion of the CHAIRMAN a hearty vote of thanks was accorded to the authors of the papers.

TUNGSTEN IN BURMA.

It is only within the last few years that tungsten and its various salts and alloys have been brought into general use. Its employment in the manufacture of filaments for incandescent lamps has, of course, made this particular use of it very familiar; but its chief value lies in the fact that when it is added to steel the latter acquires the property of "self-hardening" and requires no tempering, and this hardness it retains at red-heat. This renders it extremely valuable for high-speed cutting tools; as a matter of fact, over four-fifths of the total outturn of tungsten is now absorbed in the manufacture of ferro-tungsten, containing between 50 and 85 per cent. of tungsten and amounts of carbon varying from ½ to 5 per cent.

The salts of tungsten are also used in certain industrial processes, such as dyeing, fire-proofing, the differential analysis of tanning materials, and the manufacture of bronze colours.

Until comparatively recently the chief source of supply was the United States, but some five years ago the first serious attempt was made to develop the wolfram deposits of the Indian Empire, and Lower Burma now heads the list as the world's

greatest producer. The total production of the world is about 8,000 tons per annum of concentrates, carrying from 60 to 70 per cent. of tungstic trioxide. Of this Burma produces one quarter.

The first record of the occurrence of wolfram in Burma (according to the Quinquennial Review of the Mineral Production of India, from which these particulars are drawn) was in 1841, but prospecting was not taken up by the general public till the present century. During the years 1909-13 Lower Burma produced over 5,000 tons of concentrates with a value of nearly £400,000, and the present rate of production is about 2,000 tons of concentrates.

The ore, which always consists of wolframite, occurs primarily in veins composed chiefly of quartz, but carrying also columbite, tourmaline, molybdenite, and, very occasionally, cassiterite. These veins traverse granite and a series of metamorphosed sediments composed of slate, schist, and quartzite, and known as the Mergui series. Occasionally both tin and wolfram are found in the same lode, but this association appears to be exceptional.

The wolfram tin-bearing belt of granite and metamorphic rocks runs on northwards from Mergui and Tavoy into the Southern Shan States, and is being exploited in Bawlake State; it is also said to occur further north in the neighbourhood of Kalaw.

In India wolfram has been found in various localities, but only in comparatively small quantities.

Although the development of the industry in Burma has been extremely rapid and the profits very great, the methods have for the most part been of the most primitive description. In addition to the quartz-wolframite loads, float deposits provide a certain amount of ore, but the greater part is obtained from the lodes, which are usually worked by quarries and open-cut workings sometimes of a highly dangerous nature. The labourers are to a large extent Chinese and Telegus, with a sparse scattering of Burmese, who do not as a race take kindly to hard work of the kind involved in mining. The ore, when won, is as a rule crushed by hand and panned or sluiced. Concentrating machinery is almost unknown, but it will no doubt soon be introduced more generally, for the methods at present in vogue are wasteful and must result in permanent loss, since much of the ore now left in dumps and tailings will for economic reasons be ultimately irrecoverable.

It is now announced that the Government of India are taking energetic steps to stimulate the output of wolfram. According to the *Pioneer Mail*, the arrangements for this purpose are much on the lines of munitions legislation in this country, and the ordinance will be of a far-reaching character.

INSANITY IN MADRAS.

Some interesting figures are given by Surgeon-General W. B. Bannerman, C.S.I., in his report on the lunatic asylums in the Madras Presidency for the triennium ending 1914.

A striking fact brought out in the census report is that in 1901, 79 per cent. of all the lunatics in England were under treatment in various institutions, whereas in Madras in 1911 only 9 per cent. of those actually returned as insane were so treated, and the proportion to the total of the mentally disordered (of whom those returned as insane probably only represent a fraction) would be, of course, much less. This difference is partly due to the fact that the people of Madras have not yet recognised the value of institutional treatment in mental disease, and partly to the reluctance the people feel in removing their afflicted relatives from the family circle, especially if these relatives are females.

Unfortunately, no statistics of the incidence of insanity among the Europeans resident in Madras Presidency are available. It might be expected on *à priori* grounds that the rate would be low; as the Europeans in India are picked men and women, and if they break down mentally they return to their own country. In the chief remaining classes the incidence was found to be as follows: Eurasians (which term includes all people of mixed European and Indian blood), 415 per 100,000; Mohammedans, 34; Indian Christians, 26; and Hindus generally, 19. The high insanity rate amongst the Eurasian community is difficult to explain. To some extent it is due to a greater readiness to return their insanes as such; and doubtless the unequal battle which the community has to fight in competition with the Indian leads to numerous mental casualties. Behind these factors there is probably the fundamental fact that Europeans cannot colonise or perpetuate their race in the tropics, that degeneration rapidly sets in, and further that races of mixed European and Asiatic blood are not, as a rule, a biological success. The lunacy incidence rate, although high, is by no means exceptional when looked upon from the European standpoint, and compares favourably with that of Ireland, where, in 1907, 542 persons in every 100,000 were insane. The number of "unrestrained lunatics" in every 100,000 of the population was in Madras City, 15; in the North Division, 19; in the Deccan or North-West Division, 18; in the Central Division, 14; in the South Division, 18; and in the West Division, 27. In regard to age: those under twenty years formed 21·27 per cent.; from twenty to forty years, 42·74; from forty to sixty years, 29·12; and over sixty years, 6·87.

LAND SETTLEMENT FOR EX-SERVICE MEN.*

1. *The Importance of the Problem.*—From such evidence as is at present forthcoming, and arguing from what took place after the Boer War, there seems little doubt that a large number of the men

* Abstract of a paper read by Christopher Turner before the Economic Science and Statistics Section of the British Association at Manchester.

now serving in the forces will elect a career on the land at the close of the war. If this is so, it is clear that the machinery for providing them with land should be created without delay, and be ready before we have the ex-Service men upon our hands, probably in their thousands. Nationally and imperially it is a question of great importance. Cultivators of the soil are more needed than any other type of citizen, both at home and overseas.

It is probable that when the war is over a time of slackness will come in urban industry, which will make it all the more important that the land should employ as many men as possible. The men settled upon the land must be settled effectively and under conditions which will, as far as possible, guarantee success. They must not merely be provided with land and then left to shift for themselves. Our dominions are paying more and more attention to land settlement. Sound and attractive conditions have been created. If we are to retain our fair and necessary share of ex-Service men within the United Kingdom, we must create conditions of settlement at least as sound and as attractive.

While not grudging to our dominions a share in the number of settlers, we must ever keep in mind that the first essential is to build up the agricultural population in the mother country, and from the overflow of that population to send out to our dominions the type of men which they stand most in need of.

2. *The Sufficiency of Land in the United Kingdom.*—There is sufficient land available for a very large scheme of settlement at home. No attempt should be made to create settlements in every county. They should be created where the land and conditions are most favourable. Large areas of land change hands every year, and land for the ex-Service men could, as a rule, be obtained in the open market. Several hundred thousand acres of agricultural land change hands every year. With the exception of heavy clay, nearly any type of soil is suitable for small farming.

If areas of not less than 1,000 acres are bought, nearness to a station is not essential, as the colony would be large enough to afford social amenities of its own, and to organise a system of motor transport. The settler, under proper guidance, should make a good living off twenty-five to thirty acres in the case of a small farm, and off five to ten acres in a fruit-growing and market-gardening district. As in the case of the Small Holdings Act, compulsory clauses will be necessary, but probably would rarely be resorted to.

A certain amount of land would have to be taken from sitting tenants. There are many men holding two or three separate farms with an aggregate area of from 2,000 to 5,000 acres, in districts well suited to small farming; for the general good it would be quite legitimate to reduce the area held by these large farmers.

3. *Suitability of ex-Service Men as Cultivators of the Soil.*—It is the opinion of many in this country that to be a successful small-holder a man must have been brought up on the land; but that this conclusion is altogether unsound has been proved by the settlements in the United States and in our colonies of urban artisans, which have succeeded admirably. But the conditions of settlement for men without previous agricultural training must be entirely different from the conditions under which trained agriculturists can fairly succeed.

There is no example up to the present time in the United Kingdom of a carefully thought-out land settlement scheme where the fundamental principles necessary to success have been observed. Settlements of ex-Service men can be successful only where the right conditions have been created.

4. *Conditions of Settlement.*—Certain guiding principles must be observed which have met with unvarying success wherever scientific land settlement has been undertaken. They are: (1) Ownership rather than tenancy; (2) easy access to capital; (3) settlement in colonies rather than in isolated units; (4) effective expert guidance; (5) co-operation, or, at all events, organised buying and selling; (6) the initial years must be made as easy as possible financially.

5. *Machinery.*—If ex-Service men are to be settled satisfactorily, it is quite clear that they will have to be treated differently from the ordinary applicants for small holdings.

As has been pointed out, in most cases they will be without agricultural knowledge, and, therefore, will require special conditions. The conditions advocated should, from the point of view of securing efficiency, be created for all settlers, but in the case of the ex-Service men they must be created, or the movement will end in failure.

The county councils, in settling small-holders, have paid little or no attention to the principles enumerated above, and which should be observed in all land settlement. The Small Holdings Act has not proved itself to be a Land Settlement Act. Under it many tradesmen have been given a bit of accommodation land, or men already holding some land have obtained additional land, but the number of new cultivators placed on newly-equipped holdings is very small—only 754 up to the end of January 1914.

County councils ought not to be asked to undertake this work. Few members of their small-holdings committees have in any way studied or understood the problem of land settlement. This work of settlement should be carried out by a Land Settlement Commission, composed of highly-qualified men, and in many ways analogous to the existing Development Commission.

This Commission would naturally concern itself with settlement in the United Kingdom, possibly only England and Wales. But the question of settlement in the United Kingdom should not be kept in a watertight compartment. There should be another commission or committee possessing advisory and consultative powers only, which

would review the question of land settlement throughout the Empire, and endeavour to bring about an understanding between the Home Government and the Dominion Governments and the dominions *inter se* to co-relate the work of the different emigration agencies, and to endeavour to check the loss to the Empire of men settling in foreign countries.

The time has come when the whole problem of emigration and settlement should be approached scientifically, and an attempt be made to bring order out of the present chaos.

ARTS AND CRAFTS.

The Arts and Crafts Exhibition Society.—The Arts and Crafts Exhibition Society can hardly be said to have proved by its recent exhibition that it is abreast of the times, or peculiarly capable of adapting itself to the new conditions involved in the war. The show was, owing to the national situation, on a much smaller scale than the usual triennial exhibitions of the Society, it consisted solely of the work of members, and was open for a few days only at the Art Workers' Guild Hall in Queen's Square, so that it is impossible to estimate from it the many activities of the members. On the other hand, it is only reasonable to expect at present that a society shall show signs of vigorous life and of adaptability to its surroundings. We have all heard so much of late of the desire of the artist to take his share in the work of the country, and to assist the manufacturer to produce wares artistically superior to those of other nations, that an exhibition, however small, of the work of artists belonging to that society, which after all has done so much for the promotion of exhibitions of arts and crafts not only in England but abroad, if not of the movement itself, led one to hope that it would give some hint of how the members of so important —one might almost by this time, since the society is some twenty-five years old, say venerable—a body proposed to assist in the work which was toward. Any hopes of that kind were, however, grievously disappointed. The objects collected at Queen's Square were some of them beautiful and many of them extremely well executed, and they nearly all gave evidence of being the output of artists keenly interested in their craft and all things pertaining to it; but work with any connection with trade or manufacture was to seek. It is true that Mr. C. H. St. John Hornby showed some printing, and Mr. Vigers some hand illumination of printed books; but with the exception of these and some very workmanlike designs for printed (actually roller-printed) cotton fabrics by Mr. Alfred Carpenter, the visitor might have imagined that he was living in an age when mechanical appliances on a large scale were quite unknown. This fact is to be deeply regretted. It almost makes one wonder whether a society which in its day has done much really good work has not outlived the limits of its usefulness. No one, of course, denies the beauty of handwork, or its charm; but people in general do want to be assured that the outlook of the master hand-worker, at least, is not bounded by his craft, and that he is able and willing to come into touch with what are after all the larger interests of the country.

Within the limits indicated, the objects on view were in the main really good and satisfying specimens of their class. The stained-glass cartoons included interesting work by Mr. Christopher Whall, Mr. R. Anning Bell, and Professor Selwyn Image. The full-size plaster model of the lectern to be executed in bronze and placed in the Chapel Royal, Savoy, in memory of Mr. and Mrs. Laurence Irving, was no less worthy of notice on account of its design than of those whom it commemorates. Mr. E. W. Gimson's chair of state, heavily inlaid with ivory, was an interesting and, in some respects, successful experiment, though perhaps a trifle barbaric. The simple mahogany chair shown by the same craftsman left nothing to be desired. Mr. Wilson's jewellery was as individual as ever, and gave ample proof of the artistic sense of its maker. The work of Mr. E. Woore, too, was both fresh and interesting. Miss Frances and Miss Violet Ramsey's exhibit, though less unlike what other craftworkers are doing, quite held its own, and Mrs. Louise Powell and Miss Jessie Bayes showed excellent illumination, and Mr. Graily Hewitt's beautiful writing of "The Flour and the Leef" gave one a feeling of absolute satisfaction, unalloyed by any desire to change the page in any respect. Mr. Harold Stabler's *cloisonné* enamel, examples of which attracted so much attention at Ghent only eighteen months ago, was well represented. Mr. Emery Walker sent a very satisfactory seal design. It was, perhaps, the very excellence of many of the exhibits which made one regret the comparatively small public to which they could appeal, and the limited range of their influence.

Messrs. Ramsden and Carr's Metalwork.—In the absence of Mr. Alwyn Carr on active service in France, Mr. Omar Ramsden held the usual Christmastide exhibition at St. Dunstan's Studio, Seymour Place, Fulham. This year, as last, there was not quite so much large work as has sometimes been the case; but there was enough to give point to the show, to indicate what the artists are capable of doing, and to prove that in spite of the war their work is by no means at a standstill. The work on view included some interesting designs for memorials, including one to Lord Roberts, to be erected in his parish church of Ascot, and another to a midshipman lost in H.M.S. "Aboukir." The little cross in amber and wrought gold made in memory of the Commander of H.M.S. "Monmouth," sunk in action on All Saints Day, 1914, off the coast of Chile, from his amber cigarette-holder and the gold of the case which contained it, is a singularly satisfactory solution of what must have been a difficult problem. At the base of the amber cross is a

naval crown in gold in delicate *repoussé* work, and below that a band of work symbolising the river of eternal life. The Stanley memorial chalice for Whiteland's College, Chelsea, was both an unusual and a suggestive piece of work. Four figures, in canopied niches—representing St. Catherine of Alexandria, patroness of education and colleges; St. Martha, patroness of housewives; St. Cecilia, patroness of music; and last but not least, St. Ursula, patroness of women devoted to education, clothed in an ample mantle in which she enfolds three young girls—uphold the knop beneath the bowl of the cup, and form a peculiarly fitting decoration to a vessel belonging to a training college for women teachers. In a different vein the covered standing salt, designed and executed for the Worshipful Company of Merchant Taylors, its base supported on eight symbolic towers carrying emblematic figures of the civic virtues, amongst which is introduced a figure of St. George to mark that the piece was made in the time of a great war, was an important and interesting piece of work. The heraldic achievement of the O'Reilly family of Galgary is a beautiful and effective combination of *repoussé* silver and *champlevé* enamel, in which the heraldic mantling is very well treated. The binding of the illuminated address presented to the Bishop of Kingston on his retirement by prominent members of his diocese, was rather a triumph in its way. The dark blue leather of the cover was enriched with heavy mountings in *repoussé* silver, and yet the resultant effect was a harmonious and pleasing whole. Amongst smaller works may be noted the regimental badge brooches in hand-wrought silver and gold. The examples shown were the badges of the Army Service Corps and of the 28th County of London (Artists') Rifles, and they certainly showed, as they were doubtless intended to do, that there is no reason why jewellery of this kind should not be a work of art and retain at the same time its strict military symbolism. The exhibition included, besides the large pieces, a number of small silver objects of real artistic value and some good jewellery.

Women's Craftwork.—The *Englishwoman* Exhibition of Arts and Handicrafts is always amongst the best of the winter exhibitions devoted to women's work. In former years the work has been shown at Maddox Street, and exhibits looked rather lost in the lofty Central Hall at Westminster, though certainly at the present moment Westminster is a better centre for an exhibition than any other quarter of the town. It was doubtless owing to the war that a larger proportion of the exhibits than usual seemed to be those connected with philanthropic institutions, but the show was still far less bazaar-like than most exhibitions of its type. It included the wares of well-known workers in various departments of arts and crafts, and gave a very fair idea of what women are doing in the realm of the artistic crafts. Weaving was peculiarly well represented. The colour of Miss E. M. Mairet's handwoven dress materials, scarves, overalls, etc., was peculiarly attractive, and the work of the Shottery Weaving School, which provides work for crippled girls, was also very satisfactory. The "artree" panels of Mr. A. J. Rowley—pictures carried out in veneers of woods of various colours and qualities—were many of them very good and suggested all kinds of possibilities, though one rather wondered why they appeared at an Englishwomen's show. Miss Phoebe Rennell's writing and illuminating were very pleasing, and some of her work was well adapted to reproduction. For the rest, the exhibition contained a good deal of needlework, some of it really good, and a fair amount of lace, as well as examples of what women are doing in the way of stained glass, pottery, jewellery making, leatherwork, basket-making, printing, toy-making, woodcarving, bookbinding, photography, and various other crafts too numerous to mention.

OBITUARY.

George Wheeler.—Information has been received of the death of Mr. George Wheeler, which took place on November 28th. He was born at Newport, Isle of Wight, in 1833, and he came to London about 1853 to assist his uncle, who was secretary to a number of benevolent societies. Subsequently he went into business on his own account as a manufacturer of various essences and colouring materials. He was interested in many scientific pursuits, and devoted a large proportion of the considerable fortune which he had made to various public and private charities. He was a Fellow of the Zoological Society, and a member of the Quekett Microscopical Club, the British Sea Angling Society, and the Corinthian Sailing Club. He also gave considerable attention to nature study and model-yacht racing, and up to within a few years of his death, at the age of nearly eighty-three, he regularly went out sea-fishing.

Mr. Wheeler was elected a member of the Royal Society of Arts in 1903.

GENERAL NOTES.

Books for H.M. Forces.—The Board of Education have issued an appeal on behalf of the Camps Library, an organisation for receiving books and magazines from all parts of the country for the use of His Majesty's Forces, and distributing them continuously and systematically. The Post Office organisation has been placed at its disposal as a collecting agency by the Postmaster-General. It sends out parcels of books to all units of the army, and the camps at home and abroad. The demand for books is practically unlimited. It is, in the first instance and most largely, for good fiction, and, in particular, for the small sixpenny, sevenpenny, and shilling editions of novels (bound in cloth, not in paper covers) which have recently

become so common. This demand still continues unabated, but there is also a demand, not as yet adequately met, for books of a more solid character —*e.g.*, historical and scientific works, poetry, essays, works on economics, biographies, pocket dictionaries and grammars (particularly French and German), volumes of well-known series such as the Home University Library, pocket Shakespeares, text-books in mathematics and science. Bulky books are unsuitable. All should so far as possible be of a small size, light and easily carried and complete in one volume. Books may be handed in over the counter of any Post Office in the United Kingdom, unwrapped and unaddressed, and will be delivered free of charge by the Post Office to the depôts of the Camps Library. Other communications, or contributions towards the expense of carrying on the work, should be sent to the Secretary, Hon. Mrs. Anstruther, at the Camps Library Depôt, 45, Horseferry Road, Westminster, S.W.

New Zealand Rabbits.—In the course of a paper recently read before the Cold Storage and Ice Association, Mr. Charles Tabor gave some statistics as to the numbers of frozen rabbits imported into the United Kingdom from New Zealand. The high-water mark was reached in 1910, when the number of crates was 113,685. The figures for the succeeding years have been:—in 1911, 109,565 crates; 1912, 92,488 crates; 1913, 69,373 crates; and 1914, 69,084 crates. The falling-off during the last eighteen months is due in part, no doubt, to the war; for a large number of boats with refrigerating holds have been commandeered by the Government; freight rates have advanced greatly, and consequently selling prices have risen almost to breaking-point. Mr. Tabor is of opinion that, taken as a whole, the New Zealand rabbits are better suited for the trade of certain parts of England than other rabbits; the carcasses are larger and the fur more valuable for purposes of felting—rabbits coming from the South Island are generally very fat, partly owing to the cooler climate, and the less frequency of that curse of Australasia, drought. The number of rabbits shipped from New Zealand ports is very much smaller than that sent from Australian, but then the great difference in the areas has to be considered, and also the fact that rabbits were imported into Australia before they reached New Zealand.

Bitumen Deposit in Honduras.—According to a report by the United States Special Agent in Honduras, there has been discovered on the west coast of that Republic, in the vicinity of Juticalpa, a deposit of remarkably pure bitumen or asphalt. Prospects uncovered for over 150 yards show the bed to be of great purity, and there are outcroppings for several miles. The discovery was made by an American citizen, resident in Honduras, who has the control of the property. The deposit is some considerable distance from the Pacific port of Amapala, which will have to be the port of shipment, but is on the line of route of a new model road which the Government of Honduras is preparing to construct, so that motor transportation will soon be available. Moreover, the bed is not greatly distant from the logical line of the contemplated railway from Ampala to the interior of Honduras.

Trade of Durazzo.—The trade of Durazzo, the principal port of Albania, appears to have increased considerably during the last few years, notwithstanding the unsettled condition of the Balkans. The total value of the trade of this place during 1914 amounted to ten millions of Italian lire (£400,000), of which one-fifth represented the exports and four-fifths the imports. Austria-Hungary, in spite of the war conditions which prevailed during the last five months of last year, figured to the amount of four millions of lire (£160,000); Italy, which is now taking advantage of her favourable position on the opposite coast of the Adriatic, followed with a trade of two millions of lire (£80,000), as compared with only 700,000 lire (£28,000) in 1907; Great Britain, one million lire (£40,000); Greece, about half a million lire (£20,000); and the remainder by Serbia and other countries.

Encouraging Egret Breeding in Madagascar.—With reference to the note on the rearing of egrets and herons in Madagascar, which appeared in the *Journal* of June 18th last (p. 716), it is interesting to learn that with a view to encouraging the breeding of egrets as a private industry in Madagascar, the Governor-General of the Colony has extended for three years from May 3rd last the interdiction of the shooting of egrets and false egrets, called "vorompotsys." The raising of egrets and "vorompotsys," and the sale of the plumes gathered from domesticated birds, are authorised under certain conditions. According to a report by the United States Consul at Tamatave, breeding should commence with young birds only, whose capture is authorised at the age of 10 to 45 days. The capture of full-grown birds is forbidden. The authorised capture of young birds, etc., does not extend to Green Island and the islets of the Vohemar Bay, which are reserved as producing centres of the Vohemar administrative egret farm.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

January 19.—Lawrence Chubb, "The Common Lands of London: the Story of their Preservation." Lord Farrer will preside.

January 26.—J. Arthur Hutton, Chairman of the British Cotton Growing Association,

"The Effect of the War on Cotton Growing in the British Empire."

FEBRUARY 2.—S. CHARLES PHILLIPS, M.S.C.I., "Paper Supplies as affected by the War."

FEBRUARY 9.—PROFESSOR J. A. FLEMING, M.A., D.Sc., F.R.S., "The Organisation of Scientific Research." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, will preside.

FEBRUARY 16.—THE HON. LADY PARSONS, "Women's Work during and after the War."

FEBRUARY 23.—MISS H. B. HANSON, M.D., B.S., D.P.H., "Experiences in Serbia."

INDIAN SECTION.

JANUARY 13.—COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., late Survey of India, "The Romance of the Indian Ordnance Survey."

FEBRUARY 17.—C. A. KINCAID, C.V.O., Indian Civil Service (author of "Deccan Nursery Tales," "The Indian Heroes," "The Tale of a Tulsi Plant," etc.), "The Saints of Pandharpur." LIEUT.-COLONEL SIR DAVID W. K. BARR, K.C.S.I., will preside.

MARCH 16.—PROFESSOR WYNDHAM R. DUNSTAN, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India."

Dates to be hereafter announced:—

R. W. SETON-WATSON, D.Litt., "The Balkan Problem."

CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Optical Appliances in Warfare."

REV. P. H. DITCHFIELD, "The England of Shakespeare."

W. A. CRAIGIE, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

VICTOR HORTA, Directeur de l'Académie Royale des Beaux-Arts de la Ville de Bruxelles, "Belgian Architecture."

CHARLES DELCHEVALERIE, "Belgian Literature."

LESLIE URQUHART, "The Economic Development of Russia."

PROFESSOR T. G. MASARYK, "The Slavonic Peoples."

G. P. BAKER, "Hindu Hand-painted Calicoes of the Seventeenth and Eighteenth Centuries, and their Influence on the Tinctorial Arts of Europe."

SIR DANIEL MORRIS, K.C.M G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland."

JAMES MACKENNA, M.A., I.C.S. (Deputy Commissioner, Myaungmyn, Burma, and designated Agricultural Adviser to the Government of India), "Scientific Agriculture in India."

INDIAN SECTION.

Thursday afternoons at 4.30 p.m.:—

April 6, May 18.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

February 1, March 7, May 2.

CANTOR LECTURES.

Monday afternoons at 4.30 p.m.:—

J. ERSKINE-MURRAY, D.Sc., F.R.S.E., M.I.E.E., "Vibrations, Waves, and Resonance." Four Lectures.

May 1, 8, 15, 22.

FOTHERGILL LECTURES.

Monday afternoons, at 4.30 p.m.:—

REV. DR. HERBERT WEST, D.D., A.R.I.B.A. (author of "Gothic Architecture in England and France"), "Flemish Architecture." Three Lectures.

February 7, 14, 21.

EDWARD A. REEVES, F.R.A.S., Map Curator, Royal Geographical Society, "Surveying." Three Lectures.

March 27, April 3, 10.

JUVENILE LECTURES.

These Lectures will be given on Wednesday afternoons, January 5 and 12, at 3 p.m. The first lecture will be given by Professor John Millar Thomson, LL.D., F.R.S., on "Crystallisation," and the second by Mr. James Swinburne, F.R.S., on "Science of some Toys."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DECEMBER 20...Medicine, Royal Society of, 1, Wimpole-street, W., 5 p.m. Lieut.-Colonel Sir Ronald Ross, "The Treatment of Dysentery."

TUESDAY, DECEMBER 21...Statistical Society, 9, Adelphi-terrace, W.C., 5.15 p.m.

Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. F. A. Holiday, "The Uralsk Province and its Oilfields."

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Major J. Quayle Dickson, "The Empire's Outpost in the South Atlantic."

Journal of the Royal Society of Arts.

No. 3,292. VOL. LXIV.

FRIDAY, DECEMBER 24, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

JUVENILE LECTURES.

Two of the Members of the Council—Professor John Millar Thomson, LL.D., F.R.S., and Mr. James Swinburne, F.R.S. — have kindly undertaken to deliver the Juvenile Lectures this year. Professor Thomson will give the first lecture on Wednesday afternoon, January 5th, at 3 p.m., his subject being "Crystallisation." Mr. James Swinburne will give the second on Wednesday, January 12th, at 3 p.m.; his subject will be "Science of some Toys." Both lectures will be very fully illustrated with experiments.

Special tickets, each admitting two children and one adult, are required for these lectures. They can be obtained by Fellows on application to the Secretary.

Most of the tickets have now been issued, but a few still remain, which will be issued to Fellows who apply for them at once.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s*. 6*d*. each, on application to the Secretary.

CANTOR LECTURES ON "HOUSE BUILDING."

The Cantor Lectures on "House Building: Past and Present," by M. H. Baillie Scott, have been reprinted from the *Journal*, and the pamphlet (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, December 16th, 1915; Sir John Prescott Hewett, G.C.S.I., C.I.E., in the chair.

The Chairman, in introducing the author of the paper, said it was a great honour to him to be present and preside on the occasion when Mr. McLeod spoke upon such an important question as the jute industry in India. He had known Mr. McLeod for almost more years than either of them would care to remember, and throughout his association with him he had always noticed that whatever Mr. McLeod did he did with all his might. Mr. McLeod had been a great success in the realm of sport and in the world of commerce. The audience might feel sure that the paper would be most instructive.

The paper read was—

THE INDIAN JUTE INDUSTRY.

By C. C. McLeod,

President of the London Jute Association.

The usual custom, when reading a paper on any particular subject, is for the lecturer to give its early history; and I am going to follow this line, but only very briefly. Before proceeding, I must give the credit for some of the information I am about to give you to Mr. R. S. Finlow, B.Sc., fibre expert to the Government of Bengal, who read a most interesting paper on "Jute and its Substitutes" at the Imperial Institute in June 1912; and more particularly in the matter of statistics which were prepared with care and accuracy. I have also gathered a lot of useful information from that excellent little book "Jute in Bengal," by K. C. Chaudhuri, Travelling Inspector, Department of Agriculture, Bengal, which is full of the most minute particulars about soil, cultivation, and treatment. Mr. D. R. Wallace,

in his interesting book "The Romance of Jute," gives a most vivid narrative of the progress of the Indian jute mills from their start, and I have made use of his figures as being reliable and authentic. Finally, I am indebted to Messrs. Johnston and Hoffman, and the *Empire* newspaper, Calcutta, for the photographic slides I am going to show to you to-day. With this short explanation I will proceed with my subject.

The early history of jute lies in obscurity. It may have been cultivated in a small or large way centuries ago, and, personally, I have no doubt it was—for the reason that the natives of India are so conservative in their ways that what we may have thought was a beginning in the eighteenth century may have been as ancient as some of the temple ruins one sees or reads about in various parts of India. As a pot-herb the leaves are extensively used in India still, and I have the authority of the "Encyclopædia Britannica" for stating that jute leaves were used for this purpose from very ancient times, if the plant may be identified with the "mallows" mentioned in Job xxx. 4, "Who cut up mallows by the bushes." The same authority states: "It is certain the Greeks used this plant as a pot-herb, and by many other nations around the shores of the Mediterranean this use of it was and is still common." I might even suggest that tents used in ancient times by the great army of Mahomet were probably partly made of the fibre. I must not, however, labour this point, and if I start on the fact that we have some knowledge of jute being handled in a small way in 1746, and grown pretty freely in the northern districts of Bengal in 1804, we have at least an authentic starting-point. Mr. Finlow states that in 1829 some 20 tons of jute were exported from Calcutta, and although the next five years only saw a small advance, averaging under 600 tons per annum, the exports increased very considerably during the next ten or fifteen years, and eventually reached the very substantial figure of 80,000 tons in 1911–12.

In dealing with this subject to-day, I do not intend to give you any figures or statistics relating to the period after the war started, for, as you are aware, the whole trade was disorganised, and I will confine myself to figures ending with the 1912–13 crop. With a view to giving you some idea of the principal jute-growing districts, I have brought this map—kindly lent to me by Messrs. W. F. Malcolm and Co.—which will give you a far better idea than any description I could give you without it. You will observe that the principal districts in which jute is grown are Mymensingh, Rungpur, Tipperah and Purnea. To those engaged in the trade, however, other districts are equally well-known, and I thought it

Total acreage 3,353,850

might be of advantage to give you the official group of forty-one districts with which we are all more or less familiar. They are shown with the area under jute apportioned to each in 1912-13.

The total figures, substantial as they are, only represent about 5 per cent. of the 60,000,000 acres annually cultivated for other products in the province of Eastern Bengal and Assam. The usual custom is to estimate the outturn for the season at 15 maunds per acre or 3 bales of 400 lb. per bale, and on the whole the system has come out with a moderate degree of accuracy. It is, however, impossible, in the absence of a survey, to arrive at correct figures, and we must wait for some years before that desirable end can be attained. Meantime, the present system conduces to a very healthy gamble in Calcutta and London, which gives those engaged in the trade an annual opportunity of making or losing large sums of money. Apart from this, climatic conditions play a prominent part. You may have a large area sown without obtaining a large crop if the monsoon is fitful or deficient, and *per contra* a moderate area under favourable climatic conditions can yield a crop that exceeds all expectations and calculations. An unenviable post in connection with jute is that of Director-General of Agriculture in Bengal, who alternately comes in for the loud curses of the "bear" or the silent blessing of the "bull," or *vice versâ*.

Let me now proceed to enumerate shortly the various classes of jute. There are two principal species of jute, *Corchorus capsularis* and *Corchorus olitorius*. The former is easily distinguished by its round pods, while the latter has long cylindrical pods. (Fig. 1.) *Capsularis* is almost exclusively grown in the northern districts, while *Olitorius* is extensively cultivated in the Hooghly and 24 Pargana districts and in Western Bengal. This latter species has the advantage of being more easily decorticated than *Capsularis*, which is of considerable advantage. On the other hand, *Capsularis* plants can stand submersion better than *Olitorius*, and, generally speaking, are less easily affected by adverse climatic conditions. Notwithstanding these peculiarities, it has been proved beyond all doubt that each of these principal species of jute would yield a different class of fibre if subjected to different conditions of soil and climatic influences. I will not go deeper into the question of strength and colour, for this is also so dependent on circumstances that reliable data are not obtainable. I may, however, usefully add that the best jute is produced on the higher lands, especially if well cultivated. Jute on the lower lands is generally cut before it has time to ripen or reach maturity, owing to fear of floods and loss of plant. Another species of jute is grown chiefly on the Madras side, called *Hibiscus cannabinus*, known on this side as "Bimli" jute. It is in every respect inferior to the Bengal jute, being shorter and coarser. It has, however, come into considerable requisition in late years, owing to an improvement in the treatment and packing, and also, I believe, on account of its comparative cheapness as compared with Bengal jute. Its production has also considerably expanded during the last five or six years.

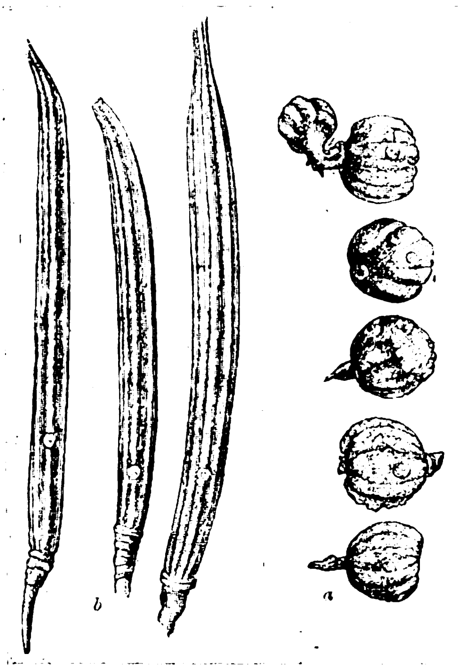

FIG. 1.—CAPSULES OF JUTE PLANTS.
a, *Corchorus capsularis*; *b*, *C. olitorius*.
(*Reproduced from the "Encyclopædia Britannica," by permission of the Encyclopædia Britannica Company, Ltd.*)

The preservation of seed has received considerable attention of late years, helped by experiments conducted by the Government Department of Agriculture. In former years seed was raised from stunted plants on the outside edges of the jute fields, and naturally, being obtained from the poorest plants, proved disappointing. As in dealing with many other industries in India, the ryot pays insufficient attention to keeping seed grown from the healthiest plants, with the result that, year

FIG. 2.—PLOUGHING THE JUTE FIELD.

after year, the same old seed from the same old and weak plants has been preserved since the original bagful came out of the Ark! A little more care and an interchange of seed would materially increase the outturn and improve the quality of the jute as well.

It would take a much longer time than I have to-day to deal at length with the intricate question of soil and its treatment, and I will merely state that jute in India can be grown in almost any soil which has a good depth and has the necessary material required to fertilise it. On the alluvial soils in Eastern Bengal, where the rivers and khals leave a rich deposit annually,

FIG. 3.—FULL-GROWN JUTE.

FIG. 4.—CUTTING JUTE.

jute grows freely without any artificial help. On the other hand, the higher lands are heavily manured and yield heavy crops, not only on this account, but also owing to the fact that jute grown on the higher lands is immune from floods and has a much better chance of ripening. An ample rainfall is, of course, an essential to supply moisture, and later on steeping water for "retting" the plant when cut. Rainwater is generally considered more beneficial than irrigation, however ample.

To take you through the various stages of ploughing, sowing, harrowing, weeding, would occupy far more time than I have at my

FIG. 5.—CUTTING JUTE UNDER WATER.

disposal, and I must shorten the description as much as possible. Early in February the ploughing commences on the low-lying lands and continues to the beginning of May on the higher lands. Fig. 2 will show you the ploughing.

The process is crude enough, and it is difficult to believe that at a later stage, when the plants appear in full growth, a scraping of the earth with a crooked piece of stick drawn by a pair of emaciated bullocks could possibly have produced such a result. After the land is ploughed and pulverised the seed is sown broadcast and in quantities of from 6 lb. to 12 lb. an acre. After this has been done the ground is raked or harrowed and the plants allowed to germinate and grow to a height of a few inches, when the rake is again used to stir up the soil and stimulate the growth of the plant. This raking process is also useful in keeping down the very healthy crop of young weeds that come up with the germinated plant. At times they grow quicker than the plants, and are very troublesome. At a later stage weeding and thinning take place, and then the plants are allowed to reach maturity without further interference. Fig. 3 shows you full-grown jute.

The period for reaping varies according to circumstances and climatic conditions. On the lowlands cutting starts about the end of June; if there is any danger of the fields being flooded, cutting is commenced even earlier. Early-cut jute is never very satisfactory; it is usually immature, short and mossy. Here is jute being cut under circumstances which I have just described under normal conditions (Fig. 4); while Fig. 5 is meant to show the conditions under which lowland or flooded jute is secured. The process of "retting," as shown in Fig. 6, usually takes anything from ten to thirty-five days, according to the time of year. In July and August, when the temperature of the water is high, the process is quicker and the jute is ready for further handling, but in September and later months it takes quite a month to "ret" the plants. The experienced grower can tell at once when the "retting" process is complete, and then the plants are taken out of the water, the fibre extracted, washed and dried—and here again climatic conditions play a prominent part. Heavy and continuous rain prevents the drying, and very often, as we know, makes the crop late in coming to market. When the jute is sufficiently dry, it is rolled up in drums and sent to the nearest market or sold locally to small dealers, who take it away to some of the large centres in country boats and dispose of it at a considerable profit. Many of these country boats make their way down to Calcutta and sell their cargoes to the jute mills along the River Hooghly.

The principal jute markets are at Naraingunge, Serajgunge, Chandpur, Madaripur, Jagannathgunge, Purnea, Julpaiguri, Koostea and Goalundo, and during the season these centres present scenes of animation and extraordinary activity. Here is a general view of Naraingunge, the principal one, which gives you some idea of the size. (Fig. 7.) It is conveniently situated on the bank of the river, which is alive with craft of every description.

At these great centres you will find not only native merchants purchasing jute, but also firms managed by Europeans buying for Calcutta mills, and Calcutta merchants buying suitable qualities for baling in Calcutta for export. A very considerable quantity of jute purchased at these up-country markets is resold to balers in Calcutta.

The transport of jute from the producing districts to Calcutta has been considerably accelerated. In the earlier days of the industry the jute came down packed in drums by country boats and river steamers, but in later years the railway has carried by far the most of it, the proportions being approximately as follows in 1912:—

By rail	about	20,000,000	maunds
By steamer . .	,,	6,000,000	,,
By country boats .	,,	6,000,000	,,
By road. . . .	,,	1,250,000	,,

The use of jute-presses in the jute districts has greatly facilitated transport. In 1891 there were only nine or ten presses in Eastern Bengal, whereas the number is now about 130. These presses are used to pack what are known as "Cutcha" bales, containing three to three and a half maunds, and are usually sold to mills and large balers. The exported bale to Europe and other countries is of a fixed standard of five maunds, or 400 lb. The packing is chiefly done in Calcutta, where the pressing-houses have increased from fifteen or so in 1885 to about forty at the present date. Fig. 8 shows the inside of a jute-press at work. Adjoining the press-house are large stores or "go-downs," where jute is assorted into the various standards required for the European market. The packing business was formerly in the hands of Bengalis, but with two exceptions this part of the trade has passed into the hands

FIG. 6.—RETTING JUTE.

of Marwarris, outside of course of the European balers, such as Ralli Bros., Duffus, Steel, and the Chittagong and Naraingunge companies.

Before leaving this part of my subject, I may just say a few words on the cost of production and the prospects of increasing the area. Mr. Chaudhuri, in his book on "Jute in Bengal," written in 1907, puts the cost of production at Rs. 3/8 per maund, but I fancy this is far below the cost of the present day, for, as with all other products, enhanced prices generally lead to an increased cost of production. It is rather difficult to account for it except in this way. Formerly, when the area was smaller, the ryot could conveniently manage to cultivate and harvest his little plots with his own family,

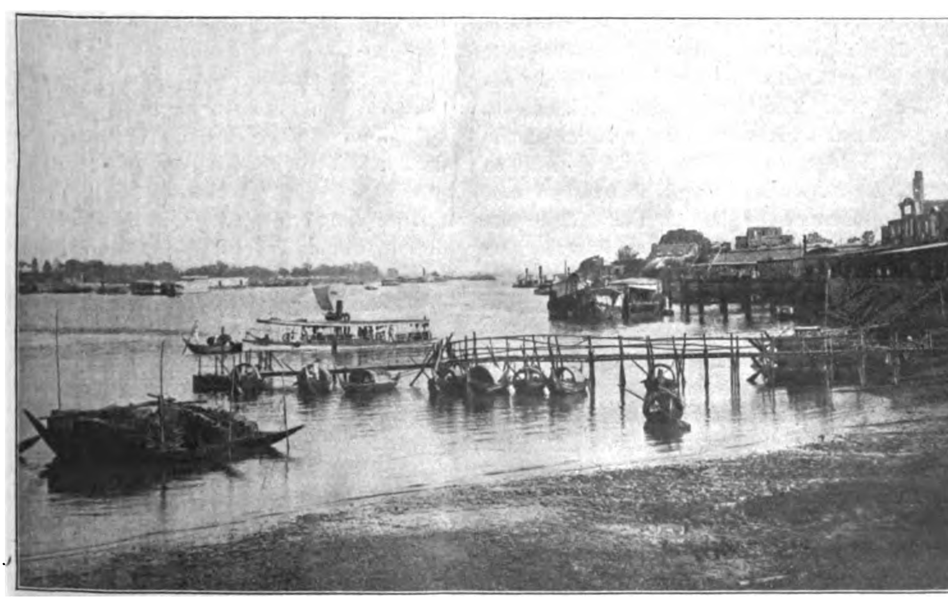

FIG. 7.—GENERAL VIEW OF NARAINGUNGE.

without incurring extra expenditure for outside labour; but with the increased demand and higher prices ruling, larger areas have been cultivated, necessitating the use of hired labour, which has materially added to the cost. This leads me to deal with the prospects of increasing the area.

It is, of course, quite a simple matter to point to the vast expanse of country available for jute cultivation, looking to the fact that jute only covers an acreage of 3,000,000 acres out of some 60,000,000 acres in cultivation in the province of Bengal and Assam. There is no lack of suitable land, especially in Assam, but the labour question absolutely prohibits expansion. It has been attempted at various periods by European firms, who have experimented with labour-saving implements; but, so far as I am aware, none of these has proved successful, and we must fall back on our old friend, the ryot. That the existing area could be made to produce a very much larger crop has been proved beyond doubt. A more scientific system of cultivation and greater care in the selection of seed and the application of fertilisers on higher lands would probably double the outturn per acre in a normal year.

Climatic conditions will always remain an important factor in determining the annual outturn on any given area. I therefore venture to state that while another million acres could be added to the existing area, so far as suitability of land is concerned, the question of labour will bar it; and we can only rely on improved agricultural methods to increase the crop. It has been stated by experts in jute that the crop has seriously deteriorated during the last ten years. The statement is confirmed by many spinners with whom I have discussed the subject. I do not think it is at all difficult to account for it. It is, I think, due to the fact that the enhanced value of the article has induced the ryot to cultivate more jute than he can handle, and that the large crop now being produced is beyond the limit of those who are engaged in it. I do not think the plant has deteriorated at all, but rather that the rush to grow it with insufficient labour has gradually, in late years, led to carelessness in the harvesting and curing of it, consequent on the desire to get it on to the market and secure the higher prices now ruling. I think this has also something to do with the excessive moisture found in the fibre in late years. The same time and trouble are not expended in drying it properly, and while the ryots who grow the jute may and do, as a rule, deliver it dry to the middlemen, the latter, especially the smaller dealers, are known to water it freely in order to increase the weight. This has been proved beyond doubt, and evidence was obtained some years ago that quite 75 per cent. of the jute reaching the Serajgunge markets was freely watered and sanded. It is difficult, indeed, almost impossible, to put an end to this practice, as the jute passes through so many hands, and I very much doubt if legislation, urged and even contemplated a few years ago, would have put a stop to it. Wet-packed jute quickly deteriorates in colour and strength of fibre, and it is not unusual to find bales of jute reaching this country with heart damage varying from 2 to 30 per cent., or even more.

Time will not permit me to give you an outline of how jute is commercially dealt in, nor am I able with the limited time at my disposal to give you anything but a very brief idea of the many uses it can be put to. Normally, it is the cheapest fibre for providing bags to carry the produce of nearly the whole world. It carries all the valuable wool and grain from our Australasian colonies, from America, South America, and, indeed, any quarter of the world where grain and oil-seeds are produced. It is used for the internal carriage of goods in every part of the globe, for covering cotton bales, tarpaulins, carpets, and even shirts are made from it in Dundee. Hem Chundra Kar, in his official report on jute issued many years ago, gives the following interesting varieties of uses to which jute was put in the Midnapur district: (1) Gunny bags; (2) string, rope and cord; (3) *kampa*, a net-like bag for carrying wood or hay on bullocks; (4) *chat*, a strip of stuff for tying bales of cotton or cloth; (5) *shika*, a kind of hanging shelf for little earthen pots; (6) *dulina*, a floor cloth; (7) *beera*, a small circular stand for wooden plates, used particularly in the poojahs; (8) brushes for painting and whitewashing; (9) *ghunsi*, a waist-band worn next to the skin; (10) *gochh-dari*, a hair-band worn by women; (11) *mukbar*, a net-bag used as a muzzle for cattle; (12) *parchula*, false hair worn by players; (13) *rakhi-bandhan*, a slender arm-band worn at the Rakhi-poornima festival; (14) *dhup*, small incense sticks used at poojahs; (15) *dola*, a swing on which infants are rocked to sleep. It has, as you know, been extensively used for sandbags in the present war. It has no real rival, and is not likely to have as far as we can see.

In the early eighties experiments were made in jute culture in Egypt, and in the Dundee Trade Report of March 23rd, 1881, the following statement appears: "Some samples of jute

grown in Egypt are being shown here. Reports on quality are varied, but, considering it is a first attempt, on the whole satisfactory. It proves beyond doubt that Egypt is capable of producing this material, and for the trade of this district this is a matter of great importance, as having the fibre grown near at hand will enable our manufacturers to compete more successfully in all markets with the Indian mills." But the project does not appear to have gone much further, no doubt on account of the cost of labour making the cost of production impossible.

A few years back *Textilose* made from paper was exploited as a substitute, but it has turned out unsuitable owing chiefly to the fact that it cannot stand immersion in water without falling to pieces. The Germans have lately exploited a fibrous plant (*Epilobium hirsutum*), which they assert will oust jute from the German markets. I very much doubt this. Even if it had the spinning qualities of jute they would find the cost of production so prohibitive that it could never compete with a fibre grown under the same conditions as jute.

I will now proceed to give you a short history of the manufacturing trade in jute. It has, like the raw material, an obscure early history, but has made up for it by coming very rapidly to the front and assuming an important position in various parts of the world. In relating the progress of jute-spinning and weaving by machinery we have ample data to go upon, and while we are unable to trace back the earlier history of hand-loom spinning in Bengal, we have records of its existence in the earliest days of our entry into that country. In this connection I cannot open the history of jute-spinning and weaving more appropriately than by giving you a paragraph from Dr. Forbes Royle's "Fibrous Plants of India," published in 1855, in which he quotes a letter from a Calcutta merchant. This is reproduced in Mr. Wallace's "Romance of Jute," and is as follows: "The great trade and principal employment of jute is for the manufacture of gunny *chuts* or *chuttees*, *i.e.*, lengths suitable for making bags. This

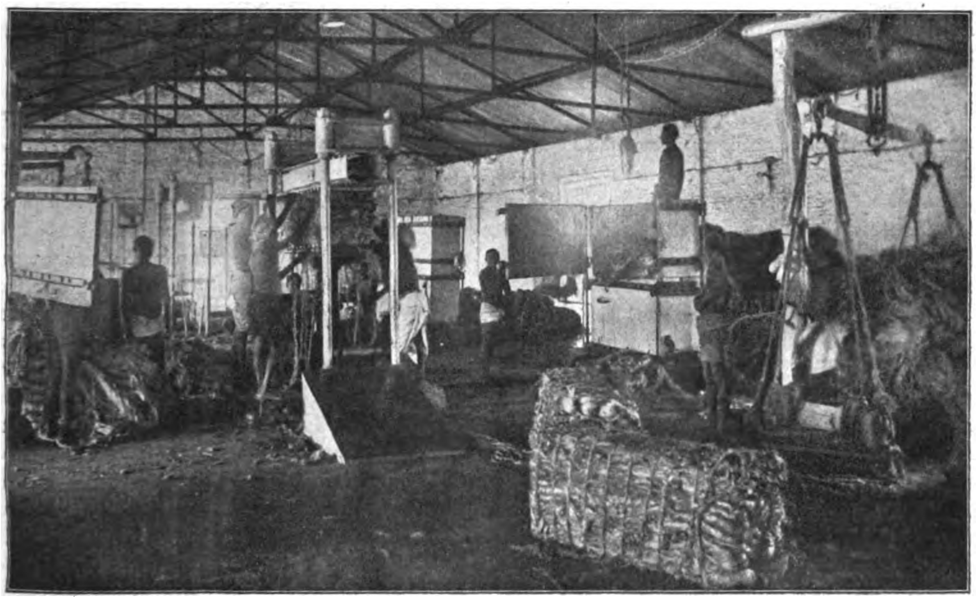

FIG. 8.—PRESSING JUTE (LASHING).

industry forms the grand domestic manufacture of all the populous eastern districts of Lower Bengal. It pervades all classes and penetrates into every household; men, women, and children find occupation therein. Boatmen in their spare moments, husbandmen, palankeen carriers, and domestic servants; everybody, in fact, being Hindus—for Mussulmans spin cotton only—pass their leisure moments, distaff in hand, spinning gunny twist. Its preparation, together with the weaving into lengths, forms the never-failing resources of the most humble, patient, and despised of created beings—the Hindu widow. Saved by law from the pyre, but condemned by opinion and custom for the remainder of her days literally to sackcloth and ashes and

the lowest drudgery in the very household where once, perhaps, her will was law, this manufacture spares her from being a charge on her family; she can always earn her bread. Amongst these causes will be discerned the very low prices at which gunny manufactures are produced in Bengal and which have attracted the demand of the whole commercial world. There is, perhaps, no other article so universally diffused over the globe as the Indian gunny bag. All the finer and long-stapled jute is reserved for the export trade, in which it bears a comparatively high price. The short staple serves for the local manufactures, and it may be remarked that a given weight of gunny bag may be purchased at a similar weight of raw material, leaving no apparent margin for spinning and weaving."

The two slides I now show will give you an idea of what the quotation I have just read so vividly describes. (Figs. 9, 10.) I give you one showing a portion of a modern mill: you will see at a glance the enormous strides that have taken place. (Fig. 11.) The entry of Dundee into the trade goes back to the year 1838, but this attempt was neither serious nor successful. However, the experimental stage of inexperience and failures gradually disappeared, and the next fifteen years saw spinning and weaving of jute carried on in Dundee with success and profit. In 1855 a beginning in spinning and weaving was made in Calcutta in earnest, and a mill was erected at Rishra, near Serampore, which produced an outturn of some eight to ten tons a day. This mill was on a piece of land which is at present occupied by the Wellington Mills, and if the spirits of the Dundee mechanics who were the pioneers of the first mill were permitted to roam about that part of the world now, and cast a glance across the River Hooghly to Tittaghur, they would indeed be surprised at the wonderful change. Four years later the Barnagore jute mill came into existence and seriously commenced cloth-spinning on an extensive scale, and this same company is still going strong. It has had a varied career, but, on the whole, I do not think that any of its original shareholders has reason to complain of the investment! The business part of the work was managed, and managed successfully, by the late Mr. Thomas Duff, founder of the firm of Messrs. Thomas Duff & Co., Ltd., who subsequently launched out on his own account, and the group of mills at Tittaghur are a standing monument to his enterprise and great success. In 1862 two more mills came into existence, the Gourepore and Serajgunge. The former is still in existence, and is one of the largest mills on the Hooghly. The Serajgunge mill, erected at Serajgunge in order to be near the producing district for the raw material, was never a great success, and was finally destroyed by an earthquake in 1897, and its machinery and plant transferred to the Delta mills, near Calcutta. These mills reaped a great harvest of prosperity up to the year 1875. This attracted public attention, and there was a rush to erect new mills, no fewer than thirteen companies making their appearance, amongst them the Hastings mill, which Messrs. Birkmyre erected with machinery transferred from their Gourock sugar factory. The inevitable result followed, and the next ten years was a period of depression owing to over-production. This led to a check in the building of new mills, and only one was added in the next five years. But in 1885 four more mills were added to the list, which remained stationary until ten years later, when extensions to existing mills and new mills increased the number of looms considerably. During this period considerable attention was paid to the export trade in gunnies and hessians, and great progress was made. Standards were established on a firm basis and the trade generally put on a sound footing. The marked improvement in the manufacture of hessians enabled the Calcutta mills to compete successfully with Dundee in the American trade, and questions in the House of Commons were frequently raised, hinting at a form of slavery in Calcutta. Eventually the Dundee member paid a visit to Calcutta, and from that date the agitation ended. Since 1895 the expansion has been rapid, in spite of periods of depression and gloom. At the present time there are some forty-six mills on the River Hooghly, with a total of close on 40,000 looms, employing very nearly a quarter of a million Indian labourers, having a capital of over £13,000,000 (including debentures and reserves), and using three-quarters of a million tons of coal per annum. The prosperity of the industry at the moment is extraordinary, and it is not easy to see what can happen to shake this trade, which is being conducted on the soundest commercial lines.

Figs. 12 and 13 will give you some idea of a modern jute mill, and of the provision that has to be made in housing the large labour force employed.

Before concluding this short history of the growth of the jute trade, both in the raw and manufactured article, I may be permitted to

give a few comparative figures to bring the present position into a more concise perspective.

The value of raw jute exported in 1829 was approximately £500; in 1913 it was close on £20,000,000. The outturn of the manufactured article in 1855 was about 8 tons per day; now it is getting on for 3,000 tons per day, or nearly four times as much as Dundee produces. The Calcutta mills, from an annual consumption of a few thousand bales in 1855, now take over five million bales, and it does not appear likely that that is the end of it; for new projects are in the air, and it is quite likely that the next few years will see a further expansion. The following list of jute-spinning and weaving mills in all countries is approximately correct, and will show you the importance of this great industry:

United Kingdom	52
Germany	36
Austria-Hungary	17
France	32
Italy	25
Belgium	23
America	16
Russia	7
Sweden	5
Denmark	2
Switzerland	2

Total	224

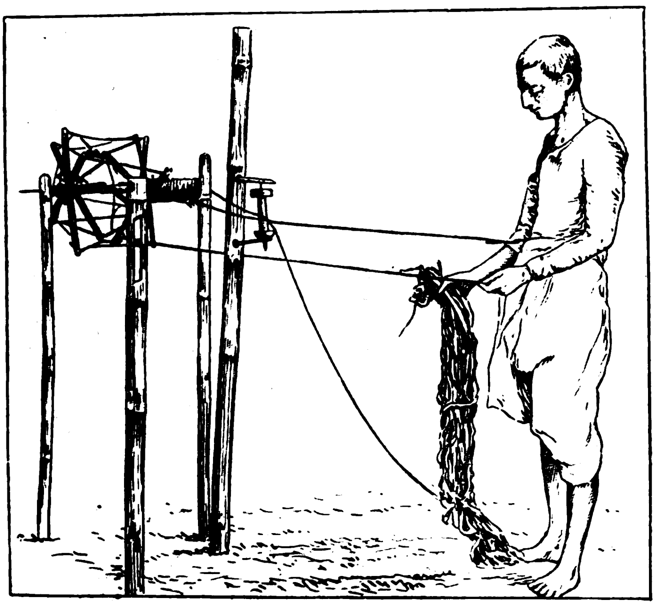

Fig. 9.—Native Hand Spinning.

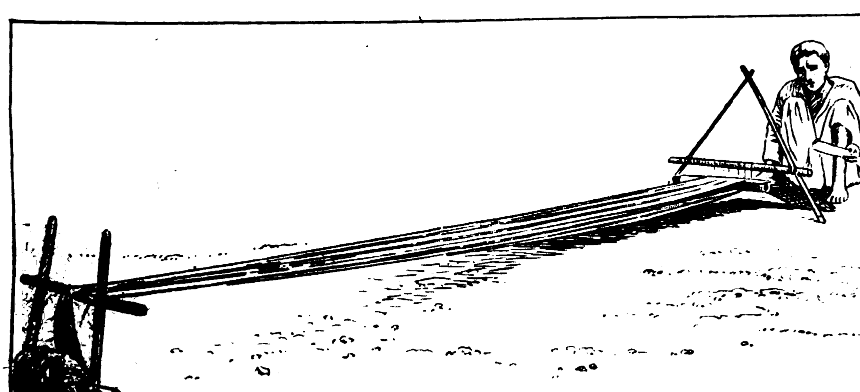

Fig. 10.—Native Loom.

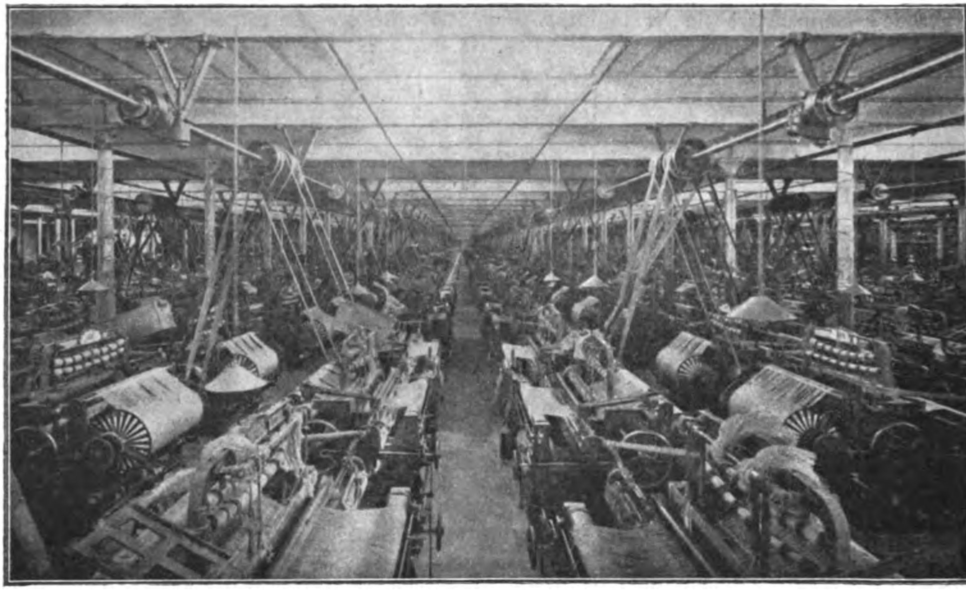

FIG. 11.—FACTORY (WEAVING).

In conclusion, you must grant me your indulgence for a few minutes more if I turn your thoughts to other vital considerations in connection with this very important industry. I have endeavoured to show you the value of this commodity to India and the Indian ryot, more especially in those districts where jute is grown. The extensive use to which this fibre is put and the enhancement in price have enabled the grower to extricate himself from the usurious kyah or moneylender, and generally to improve his condition materially. As in most products which are in demand, the cost of production, as shown in a previous part of my paper, has risen considerably, but there is still a substantial margin of profit, and that will, I think, continue to benefit the grower more and more as time goes on. In former days the

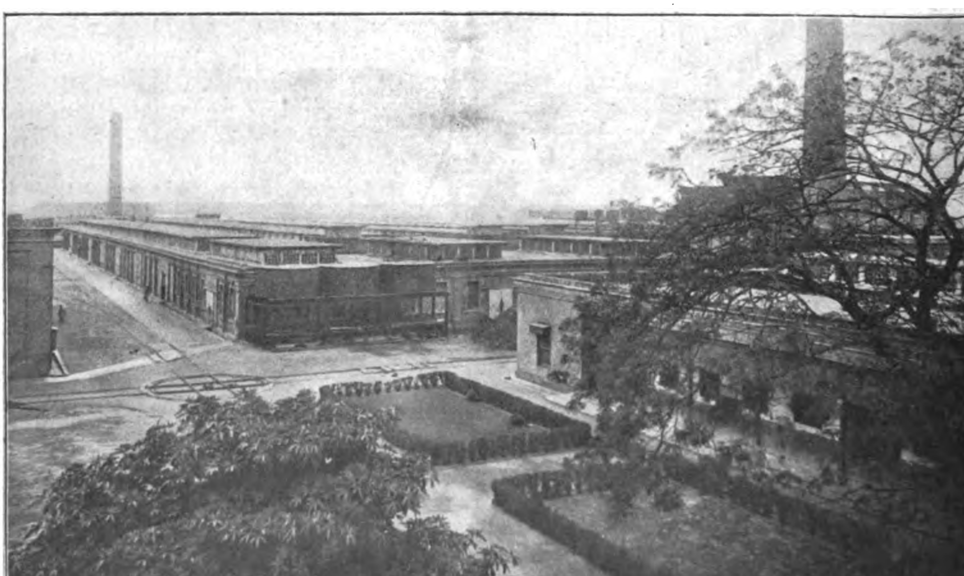

FIG. 12.—GENERAL VIEW OF JUTE MILL.

cultivator was obliged to grow jute and dispose of it at a fixed arbitrary rate from which he got no benefit, and at times not a living wage; but the industry, like many others, has undergone great changes and the old order of things is gradually passing away, to the distinct advantage of the ryot, and incidentally of the country. Jute, as you are all aware, is a monopoly of Bengal, and as such could be much more advantageously handled than it has been in the past. Every country in the world has up to now been allowed to have its share of it on the same terms and conditions as we in this country get it. In my humble opinion, this is altogether wrong. In saying this I may be treading on the toes of Free Traders, jute could be shipped from Calcutta to Hamburg direct except in a "Hansa" liner. There was evidence that a few years' time would see Germany purchasing jute from natives of India direct with Hamburg arbitration, and, indeed, I am not at all sure that a beginning had not been made in this direction. They at the same time secured a market for their manufactured goods that precluded serious competition from Dundee or Calcutta by a system of tariffs, and went so far as to dump their excess production on our markets when it suited them. Surely it is high time all this was stopped, and that we opened our eyes to the fact that we have the monopoly of a raw material that cannot be grown success-

FIG. 13.—GENERAL VIEW OF COOLIE LINES.

but I cannot help thinking that the day of Free Trade as politically understood is now a thing of the past. Contrast our action for one moment with that of the only German colony that grew any fibre at all, *Sisal* hemp, in East Africa. Their conditions were that the fibre should be grown under German supervision, decorticated by German (Krupp's) machines, shipped to Germany only in German ships, insured in a German company, sold by German brokers and subject to German arbitration! I do not see how they could have drawn the net much closer. I have, for many years before the war broke out, watched the position as regards jute. This same process was being exploited, and they had already gone as far as securing that no

fully elsewhere, and acted accordingly. I am familiar with the arguments that can be brought against this view; but if this great war has proved anything so far, it has amply proved that we have lost golden opportunities of benefiting our own subjects and our own colonies, owing to our failure in grasping the insidious machinations of German traders. With the mask thrown off by our enemies, and the actual position brought to light in a manner which cannot be controverted, are we again to lose an opportunity that may never return by adopting a fatal "wait and see" policy, or are we to gird our loins and prepare ourselves against the trade invasion that will assuredly take place when this war is over? Jute will

be one of the most urgent needs, and every effort will be made by Germany and Austria to buy it on the old terms. Are we going to sit down and allow them to do so with an article of which we hold the monopoly, and one that neither of these countries can do without? The port of Calcutta has been enlarged out of all recognition to accommodate the increased trade in exports, chiefly jute, which is the most valuable export from Bengal. Large docks have been built and will probably have to be doubled. The port of Chittagong was opened mainly to provide for the export of jute. Many millions have been spent on these improvements, and yet countries who have not contributed one penny towards them are, under the favoured-nation clause, benefiting as freely as the country that is paying the interest on the colossal outlay expended on these ports. I think it is time that some different system of handling Bengal's valuable monopoly of jute were brought into action, and that those who wish to have a share in this great trade should be made to contribute to the cost of the ways and means of handling and transporting it. If we do not act, and act promptly, it is easy to see what will happen. After this war is over, if nothing is done, Germany and Austria will receive our jute on the same terms as British subjects, without contributing a farthing towards the heavy expenditure and consequent taxation that is imposed on the country that produces this monopoly. Ought we not now to realise this and have an effective remedy? I think so.

DISCUSSION.

THE CHAIRMAN (Sir John Hewett, G.C.S.I. C.I.E.) said he needed no authority beyond the applause with which the paper had been received to enable him to express the appreciation of the audience for the manner in which the author had given all the information which was available with regard to the cultivation and the manufacture of jute, and the uses to which it was put. The illustrations had been most useful in showing the system of cultivation and the old, crude methods of spinning and weaving, and the modern machinery that had brought the industry to its present high level. An industry the total export trade of which amounted to 40 millions sterling a year was something to be proud of. Like many other things in India—the posts, railways, telegraphs, etc.—the great industry was entirely due to the capital and enterprise of the British. That was a fact some people were very apt to lose sight of, but one that should always be borne in mind. He was afraid that he knew very little about the cultivation and manufacture of jute, as he belonged to a part of India where no jute was to be found; it was only by a happy chance that once, when travelling in Eastern Bengal, he was able to see jute under cultivation and the methods in the villages by which it was spun and woven. Later on, when he was in charge of the Department of Commerce and Industry, two matters came before him in connection with jute—one a comparatively small one, and the other of real importance. The first related to the question of imposing a small export duty on jute in order to provide funds for the Calcutta Improvement Trust; and the second, the very important question of the "Watering of Jute" Bill. He knew that at the time in Calcutta there were very varying opinions as to the merits of this. There was no doubt that, by an admixture of water and sand, jute had been very seriously adulterated with great harm to the trade, but he was unable to see any means by which legislation could be effectively applied to stop the process of adulteration; it seemed to him—and it was the view eventually taken by the Government of India and the Secretary of State—that the more effective means of preventing adulteration was for the trade to take the matter into their own hands. He believed that action of the trade had had the desired effect, and that there was nothing like the adulteration there used to be. Mr. McLeod had referred to the manner in which the Government allowed jute to be exported to Germany without any charges whatever for the benefit of the State or local funds. Throughout the history of our dealings with Germany he thought it would always be found that the struggle had always been to prevent the Germans robbing us of our commercial advantages. In the Middle Ages, when Englishmen were in need of something obtainable only in Germany, the Hanseatic League always made them pay through the nose for it, and in the present day that process flourished as much as ever. On the other hand, we in the most lamb-like manner offered all the things we had to Germany in the cheapest possible market. We allowed them to resort to all those processes to which Mr. McLeod had referred, and we looked on while State-protected industries were dumping their products on our markets without making any efforts to protect ourselves. Whatever our principles were before the war, whether we were Free Traders or Tariff Reformers, or were satisfied that neither of those dogmas was quite sufficient to bring us salvation, we all felt quite sure that in the economic world, as well as in social and political matters, we should have to revise our old ideals. Therefore he had no hesitation in saying that he was personally a very strong supporter of the author's view that we ought to get the Government to put an export duty on jute. But he would go a great deal further. He did not see why, while our allies and dependencies were entitled to get our raw products on the best possible terms, countries like America, which chose to put a very heavy import duty on the manufactured articles which we sent to them, should have raw jute without an export duty. Although

he would apply as much restriction as possible to German trade, in this particular instance he would apply it to other people too. As Mr. McLeod was the Chairman of the Indian Section of the London Chamber of Commerce, he should now set about organising arrangements by which the Government should be forced to consider the question. He should also give his attention to any other matters in which it appeared that he could effectively do good to British and Indian trade at the expense of German trade.

SIR WILLIAM DUKE, K.C.S.I., K.C.I.E., expressed his appreciation of the comprehensive paper. He himself had had a fairly close connection with jute during a great part of his existence, having lived within sight of it when it was growing, and within scent of it when it was *retting*—and the scent was not exactly that of the honeysuckle. There was no question of the extraordinary value of the industry. It was worth annually from 20 to 30 millions sterling to the peasants of Bengal, Assam, Berar and Orissa, and supported in addition something like a quarter of a million factory operatives and their dependents. What it exactly produced for shareholders, agents, dealers, and shippers, he did not know, but it was something very handsome indeed. The author seemed to think that the position was so stable as not to be seriously threatened; he feared none of the competitors which had yet appeared. It was to be hoped he was right, but the future success of a monopoly industry like jute depended entirely upon the cost of production being kept stable and low. A textile which was principally required for bags could undoubtedly be produced at a price. If there was no competitor it was simply because jute at present was able to undersell every competitor. How long that might continue with the rising cost of production it was hard to say. Mr. Chaudhuri, five years ago, estimated the cost of production at three rupees eight annas a maund. but it was probably now over four rupees. With the extension of cultivation and the increasing prosperity of the cultivator more and more resort was had to hired labour, and the price of such labour in Bengal was now high; the rates in the neighbourhood of Dacca and Serajgunge had recently been as high as a rupee a day. Were there only the natural and inevitable increase in cost of production to be feared, he certainly thought that jute might look forward for a long time to being able to hold its own, but one had to consider the extraordinary fluctuations of raw jute. Within a period of two to three years he had known the price of raw jute to vary between 200 and 300 per cent.; he had known it vary in Calcutta from a little over five rupees to fifteen rupees a maund within a comparatively short time. That was not a healthy condition. An excessive price for the raw material must act as a bonus on the production of competing fibres. It might be said that all agricultural products were subject to fluctuations, but he knew none which were subject to such great fluctuations from such comparatively small causes. These fluctuations occurred with variations of perhaps not more than 10 per cent. in the crop. It had been said that the great variations were largely due to gambling in the product in Calcutta. He could not suggest a remedy, but one had to be found. There were only about fifty jute mills in Bengal and the bulk of the raw produce was worked up in the country, and the fifty jute mills were in the hands of a smaller number of managing firms. The extraordinary fluctuations were not good for the cultivator, and did not tend to a steady increase in the area cultivated. It was not good that the Indian cultivator should be paid for his crop one year twice as much as it was worth and next year not get a remunerative price. About nine years ago he was in Orissa, a country that cultivated very little jute, but was capable of cultivating a good deal. In 1905, or perhaps it was 1906, there was a great jute boom in Bengal, the price going up to something like ten rupees a maund. This appealed to the Orissa cultivator, and next year the area cultivated was greatly extended, but that year there was a good crop all over the country and prices fell, and the Orissa cultivator was offered six rupees for a crop that in the previous year would have fetched ten rupees. He decided to hold up his jute, but in the end had to let it go at six rupees, and for some years that was the end of increasing jute cultivation in Orissa. The fluctuations had prevented the release of the cultivator from the hands of the moneylenders. The people who really controlled the jute trade were comparatively so few that it ought to be quite possible for them to find a remedy, and he thought it urgent that they should do so.

MR. J. E. WOOLACOTT thought it was well that the importance and value of the jute industry should be better known in this country than they were at present. It was a modest industry. If Calcutta were in America there would be a "Jute King," and probably Mr. McLeod himself would occupy that exalted position. In India the jute-mill owners were content to go on quietly amassing their millions, to the great glory of Scotland and to the benefit of Bengal. The industry was of such great importance to Bengal that if it were removed Calcutta would sink to the level of Bombay and other minor cities in India! But, as Mr. McLeod said, there was no apprehension on that point. The industry was flourishing, and if Mr. McLeod's fiscal policy was carried out it would no doubt flourish more than ever, because the raw material would be cheaper—and perhaps Dundee would be allowed to share in that great advantage. Everybody was in favour of preventing Germany from attaining the position she was about to attain when the war broke out, but there were other interests involved besides those of Germany and Austria—France and Italy, both of whom were large importers of jute, and also the interests of the cultivator in Bengal. In the end any decision come to must be based primarily upon the interests of the people

who produced the jute. He was quite in sympathy with the main object Mr. McLeod had in view, but the question was a very complicated one, and part of a very much larger question that would have to be solved at the end of the war. It would be a very valuable thing if the commercial bodies with which Mr. McLeod was connected would consider the matter very carefully and give those who were not so well versed in the subject some information on which to base a judgment.

Mr. L. R. Windham Forrest asked whether the author could supplement his remarks by explaining by what method jute was prepared for the market.

Mr. T. J. Bennett, C.I.E., in proposing a vote of thanks to the author, said that Mr. McLeod had shown that the subject was one of great human interest. For instance, he had shown that jute served as a swing for infants, as a rope for the neck of the criminal, and an excellent substitute for the penitential hair-shirt. In thinking of the deterioration of jute one recalled the tragedy of indigo. There were both superficial and fundamental differences in the economic conditions of jute and indigo, but the experience with regard to the latter should be a warning not to allow the deterioration in the quality of jute to continue. The readiest remedy was to ask Government to look into the matter, but it was a question which the leaders in the trade might far better look into for themselves. There was a time when, if so contested a question as preferential treatment of jute or any other product had been discussed in the hall of the Society, there would have been "wigs on the green." But there had been some very plain speaking that afternoon, and no protest had been raised, the reason being that nowadays anywhere, and at any time, anybody could say what he liked on economic questions. The attitude of the audience that afternoon on the question was unmistakably in favour of, at all events, approaching the question from a new point of view. Jute was a product favourably situated for having a place in a great scheme of Imperial preference. It was practically a monopoly, and our enemies were quite as eager to buy it as we were to sell it. He thought we should be justified in protecting our own interests by acting on the suggestions that had been made in the paper and the discussion. Mr. McLeod was a very influential man, and as Chairman of the Indian Section of the London Chamber of Commerce could undertake to see that there was adequate information available on the question. The whole subject of Imperial preference had to be gone into, and a solid foundation should be provided for future building. Sir John Hewett was particularly fitted to take the chair on such an occasion, because, as everyone in India knew, there was no man who could give a sounder opinion on a commercial subject. It had been a privilege to have him present, and in thanking him they would wish him God-speed on his journey to India, where he would be warmly welcomed. They wished him a pleasant journey and a speedy return to England, where he was doing such good work.

Sir Bradford Leslie, K.C.I.E., seconded the motion. He said he was one of the original engineers who constructed the Eastern Bengal Railway, which carried the greater portion of the jute, and at the time he was building the floating bridge across the Hooghly at Calcutta he was also officiating as engineer to the municipality of Calcutta. They had a large area called the "Reclaimed Square Mile," near the salt-water lakes, where they deposited the Calcutta sweepings, and he was struck with the fine quality of the mould that resulted, and the rank luxuriance of the weeds growing thereon; he cleared a small patch of the ground and planted some ordinary jute seed, which after a good rainy season grew 50 per cent. taller and twice the thickness of stem of ordinary jute. He did not pursue the matter any further at the time, but he believed there were millions of tons of such mould which might be utilised for fertilising the land on which jute was grown, and no doubt the municipality would be glad to get rid of the stuff. He hoped when the war was over the railways would be extended to facilitate the jute trade.

The motion was carried unanimously.

Mr. McLeod expressed his thanks for the vote. He was sorry time did not permit him to give Mr. Forrest a description of how jute was manufactured into yarns and cloth, but it would take a long time and he should be glad to do it privately. It was of peculiar interest to him that the vote had been seconded by Sir Bradford Leslie, as the first entertainment he ever went to in India was at Combermere Lodge, then Sir Bradford's residence, and now the residence of the superintendent of the jute mills in that quarter.

The Chairman also briefly thanked the audience.

The meeting then terminated.

SUGAR IN BRITISH GUIANA.

The sugar production of British Guiana and the possibilities of its expansion are discussed by Professor J. B. Harrison and Mr. C. K. Bancroft in the *Bulletin* of the Imperial Institute. The area under this crop, about 72,000 acres, is practically the same as it was eighteen years ago, while the average yields are somewhat higher. In normal years the Colony exports about 110,000 tons of sugar, 3,600 casks of molasses, 2½ million gallons of rum, and 12,000 tons of cattle food. If there were any certainty of sugar prices remaining remunerative, a very great extension of sugar cultivation would take place. It is estimated on very conservative grounds that the readily available area of land well suited for sugar-cane cultivation

in the eastern part of the Colony could produce 1,000,000 tons of sugar, while another 1,500,000 tons might be obtained on lands in the north-western districts. It is, however, admitted that scarcity of labour is an obstacle to expansion.

The sugar-manufacturing industry has been compelled by economic reasons to develop into one almost solely for large capitalists and companies. Still a few smaller cultivators pursue their business with fair success. Cane-farming is carried out to some extent by small proprietors and villagers, and its extension on a mutually profitable basis to the farmers and manufacturers is deemed very advisable. The average annual value of the cane products exported for the past twenty-three years has been £1,361,195. In the 'nineties, two-thirds of the sugar produced were exported to the United States, and almost one-third to the United Kingdom, the rest going to Canada; but in 1912 and 1913 about 70 per cent. went to Canada, 20 per cent. to the United Kingdom, and 8 per cent. to the United States.

MANUFACTURE OF COPRA IN BRITISH HONDURAS.

During the eight months, January to August, 1915, there were shipped from Belize 40,649 lb. of copra to the United States, and over 100,000 lb. to the United Kingdom, or more than the total shipments for as many previous years.

The meat of small coconuts, nuts broken in handling, and nuts that have sprouted can be profitably used in preparing copra, and, unless the local market price of first-class nuts exceeds $14 (about £2 17*s*. 6*d*.) per 1,000, such nuts can be used as well. Copra is worth 4 and 5 cents (2*d*. and 2½*d*.) a lb. in Belize. A thousand nuts should yield 400 lb. of copra, but the fancy prices that have been paid for coconuts during the past six years forbade consideration of making the article; as much as $30 (£6 3*s*. 4*d*.) per 1,000 has been paid for coconuts in Belize.

According to a recent report by the United States Consul at Belize, the manufacture of copra in British Honduras is not very expensive, the meat extracted from the nut being dried in the sun in five or six days, or under cover in the rainy season. The copra is then ready for bagging or shipment. The oil, if at all tainted, can be profitably used in soap manufacture. First-grade oil is used in making a cheap but wholesome grade of butter, which is now used extensively in European countries.

Coconuts are being extensively planted in British Honduras. It is a very profitable industry, even when nuts sell at $12 (£2 9*s*.) per 1,000. Copra manufacture is, however, a new venture in the country, but one that will, in the Consul's opinion, succeed and increase. No attention was paid to it until this year.

The immediate, even though slight, effect on trade will be the demand for bags and bagging.

OBITUARY.

Viscount Alverstone, G.C.M.G., LL.D., D.C.L., F.R.S.—By the death of Lord Alverstone at his house near Cranleigh, Surrey, on the 13th inst., the Society loses not only one of its most eminent Fellows, but one who had for many years taken a very keen interest in its welfare. Nor was he the first of his family to be associated with the Society's work, for his father, Thomas Webster, Q.C., the eminent patent lawyer, was one of its most active and useful members in the middle of the last century. Thomas Webster became a member in 1838, and took a leading part in the renovation of the Society, which ended in its obtaining its Charter in 1847. He was a member of the Society's first Council, and served on it until 1850, when a dispute about the administration of the Society's affairs arose between him and Mr. Henry Cole, the result of which was that Mr. Webster lost his seat upon the Council. He never after this took any part in the work of the Society, but he continued a member until his death in 1875.

Mr. Richard Everard Webster, as he then was, became a member of the Society in 1878. In 1883 he was elected on to the Council, and he remained on it, holding various offices, until the time of his death. He was Chairman in 1890, and during his term of office the Council was appointed the Royal Commission for the Chicago International Exhibition. In 1892 the by-laws relating to the election of the Chairman of Council were suspended by a General Meeting of the Society, in order to enable him to remain in office until the business of the Exhibition was concluded. This is the only case in which a Chairman has served for more than two years continuously. He was in America on the business of the Behring Sea Arbitration in 1893, and paid a visit to Chicago, where he remained some little time, and made himself extremely popular with the American executive as well as with the British exhibitors. His experience at Chicago led to his serving on the Royal Commission for the Paris Exhibition of 1900, and afterwards on that for the St. Louis Exhibition in 1904.

At the expiration of his term of office as Chairman, he was nominated by H.R.H. the Prince of Wales (King George V.) as a Vice-President, and on the death of King Edward in 1910 he was elected President of the Society, retaining this office till the following year, when H.R.H. the Duke of Connaught accepted it. Not only during his tenure of office as Chairman, but both before and after those years he took an active part in the Society's administration, and his attendance at the meetings of Council and of the Finance Committee was, despite the numerous calls upon his time, fairly regular until the serious, and ultimately fatal, illness, which began about two years ago.

Born in 1842, he was educated, like his father, at Charterhouse and at Trinity College, Cambridge.

His degree was respectable, for he took honours both in mathematics and in classics, being 38th Wrangler and in the third class of the Classical Tripos. His chief reputation at the University was as an athlete, for he certainly was one of the finest long-distance runners that the University has ever produced, remembering that his feats were always accomplished on grass, before the days of the cinder path, which indeed was not introduced at Fenner's until after he had gone down. To his contemporaries at Cambridge his rapid and great success at the Bar came as something of a surprise, for though he was always steady in his work, as in everything else he undertook, it was not yet recognised that his abilities were anything above the average.

His legal career has been fully dealt with in the numerous obituaries which have appeared in the daily papers, and not much need be said about it here. Suffice it to record that he was called to the Bar at Lincoln's Inn in 1868, and very rapidly obtained a large and lucrative practice. To some extent his success may have been due to his father's reputation, and to the fact that his father's friends fully appreciated the efforts he made as a young man to clear off certain liabilities incurred by the unsuccessful speculations of Mr. Thomas Webster, and were all the more ready to assist his son. His success, however, was certainly due, not to any adventitious help, but as he himself has said in the "Recollections" he published about a year ago, to his enormous capacity for work. He had a marvellous memory for details, and grudged no amount of pains in getting up his cases, or in mastering the *minutiæ* of anything he undertook. He would begin work long before most of his colleagues were out of bed, and continue at it steadily throughout the day. He never spared himself, and perhaps he was not much inclined to spare others not gifted with his iron constitution or his powers of strenuous endurance. Thus it happened that his capacity for painstaking work was soon recognised, and ten years after he was called he was certainly making a larger income than anyone of his standing.

When Sir Hardinge Giffard (Lord Halsbury) became Lord Chancellor, Mr. Webster was offered the post of Attorney-General, although he was not at the time in Parliament. He soon, however, obtained a seat for Launceston, and not long after he was elected for the Isle of Wight—a constituency which he represented for fifteen years. He naturally looked forward to the post of Lord Chancellor, but as Lord Halsbury's long continuance in office prevented the occurrence of a vacancy, he had, to his own bitter disappointment, as his friends knew, to accept in 1900 the office of Master of the Rolls. A few months after his appointment Lord Russell of Killowen died, and Lord Alverstone, as he was then created, became Lord Chief Justice. Although for the time he was not quite consoled even by this high office, he very soon realised how great that office was, and very shortly after his appointment he expressed himself in private, and evidently with perfect truth, as fully satisfied with his position.

Of his career as Lord Chief Justice, as of his career at the Bar, it is unnecessary to speak here. There seems little need at the present moment to draw comparisons between Lord Alverstone and other holders of his exalted office. Certainly, in his hands it lost nothing of its ancient dignity and reputation. In the discharge of its duties he acquitted himself to the full satisfaction of the Bar, and by his conduct in office added to the respect and regard in which he was held by the members of his profession. How great this respect was, was shown by the meeting held under the chairmanship of the well-known Parliamentary counsel, Mr. Samuel Pope, a strong Radical and a Home Ruler, to protest against the animadversions which had been made upon Sir Richard Webster in connection with the Parnell case, and to testify to the high consideration in which he was held by the Bar. In this light he was indeed ever regarded by his friends and acquaintances from the time that he was an undergraduate at Trinity down to the date of his death. A man of the finest character, he always bore a high reputation for straightforward and honourable behaviour, and he won the admiration of all those with whom he was brought into contact, either professionally or in the many other activities—religious, social, political, diplomatic, or even sporting—in which he was engaged.

Sir Thomas Jackson, Bt.—Sir Thomas Jackson, chairman and director, and late chief manager, of the Hong-Kong and Shanghai Bank, died suddenly at the bank in Gracechurch Street on the 21st inst.

He was born in 1841, and after being educated at Castle Knock, Ireland, he entered the service of the Bank of Ireland, Belfast. In 1864 he proceeded to India, to the Agra Bank, and two years later joined the Hong-Kong and Shanghai Bank. He was a member of the Legislative Council for Hong-Kong from 1884 to 1886, being the first elected member. He was knighted in 1899, and received a baronetcy in 1902.

Sir Thomas was also chairman of the Imperial Bank of Persia, and held appointments on the boards of several other banking and insurance companies, including the London County and Westminster Bank, the Union Discount Company of London, the Royal Exchange Assurance Corporation, and the Yorkshire Penny Bank.

He was elected a member of the Royal Society of Arts in 1900.

Sir William Wilson Mitchell, C.M.G.—The death is announced of Sir William Wilson Mitchell, which took place at Colombo, Ceylon, on the 15th inst. He had been a member of the Royal Society of Arts since 1900.

Sir William was born in Edinburgh in 1840. In 1863 he went out to Ceylon, where he devoted himself to mercantile pursuits and to tea-planting. He was the first to introduce the cotton industry

into Ceylon. In 1875 he was appointed a member of the Legislative Council; he rendered many services to the Government, and took a prominent part in the development of Ceylon. He was appointed one of its representatives at the Paris Exhibition of 1900, and in recognition of his services he was created a knight in that year. He had previously received the C.M.G. in 1895. He was senior partner of the firms, Messrs. Darley and Butler, London, and Messrs. Darley, Butler and Co., Colombo, and Consul for Mexico in that city.

GENERAL NOTES.

Serbian Orphanage.—Under the patronage of the Serbian Relief Fund a juvenile lecture on "The Home Life of interesting and beautiful Birds of other Lands" will be given by Mr. James Buckland, at the Whitehall Rooms, Hotel Metropole, Whitehall Place, S.W., on Tuesday, January 4th, 1916, at 3.30 p.m. Tickets, 5s. each, can be obtained at the usual agencies, or from Mrs. James Buckland, 29, St. Thomas's Mansions, Westminster Bridge, S.W. The proceeds will be given to the Children's Fund to build an orphanage in Serbia.

Gas from Peat.—According to a Friesland newspaper, the municipal gasworks at Akkrum in that province are extracting gas from peat mixed with coal. It is stated that if peat alone were used the retorts would become too hot, because of the steam created by the moisture always found in peat. Accordingly the retorts are filled with two parts in weight of coal to one of peat. The peat—as well as the coal—produces about 30 cubic metres of gas per 100 kilogrammes (220 lb.), and, according to a report by the United States Consul at Amsterdam, the gas produced from this mixture is declared to be of excellent quality. The peat is entirely consumed in the process, and therefore yields no by-products, as coal does in tar and coke; but the use of peat is a great saving of coal, which is important in Holland now, where all coal, and particularly gas coal, is scarce, and has to be imported from a distance at heavy cost. Peat, on the other hand, is plentiful, particularly in Friesland, and is dug in the vicinity of the gasworks.

Experiments in Cultivation of the Cork Tree in Sardinia.—A Sicilian journal, *I Nuovi Annali di Agricoltura Siciliana*, has lately published some interesting notes on the experiments made by Signor G. Cusmano, an inspector in the service of the Government penal settlements in the island of Sardinia, in the cultivation of the cork tree. The possibility of grafting slips of this tree on the evergreen oak was suggested by the botanical similarity of the two plants, and also by the latter's greater longevity. The experiments were made in 1913 at Sarcidano (province of Cagliari), and at Mamoni (province of Sassari). A large number of standards of the evergreen oak, about 3 ft. high and eight to ten years old, were grafted with shoots and with buds of the cork plant. These grafts were successful, and the operation repeated on a more extensive scale in the forest of evergreen oak of Castiados, in the province of Cagliari, was equally satisfactory. It was found that the best results were obtained from buds inserted on the stem and not on the branches of the tree. Besides yielding a more abundant and superior quality of bark, it is claimed that the life of a tree as a cork producer can be doubled, and the value of the forests of evergreen oak considerably enhanced, by adopting this method. It is estimated that during a life of 300 years such a tree would yield from 30 to 37 harvests of bark, as compared with the cork tree, which in 150 years can only be stripped 15 to 17 times. At the present time the timber of the extensive forests of the evergreen oak in Sardinia are only used for the production of charcoal. If transformed by this method into cork forests, each tree might yield 50 kilogrammes, to the value of 40 francs (about 1 cwt., worth 32s.), of excellent bark at each stripping.

Decrease in Number of Live Stock in France.—The result of a census of live stock existing in France on July 1st last has just been published by the Minister of Agriculture. From this it appears that on that date the total number of animals of various kinds was as follows:—

Horses	2,227,209	head
Mules	152,266	,,
Asses	332,244	,,
Cattle (bovine)	12,281,849	,,
Sheep	13,483,189	,,
Pigs	5,490,736	,,
Goats	469,487	,,
Total	34,436,980	

As compared with a census taken eighteen months ago, these figures show a falling-off of 31 per cent., or nearly one-third, in the number of horses. No census since 1840 has shown such low figures.

Agricultural Production of the United States, 1915.—According to the *Pacific Rural Press*, the last harvest seems to have been a record one. The following figures, given by that journal, show the totals of the different crops harvested this year:—

Description of Crop.	Quantity.
Winter wheat	685 million bushels
Spring wheat	206 ,, ,,
Maize	2,673 ,, ,,
Oats	1,141 ,, ,,
Barley	195 ,, ,,
Rye	43 ,, ,,
Buckwheat	17 ,, ,,
Potatoes	406 ,, ,,
Tobacco	1,035 million lbs.
Hemp	16 ,, bushels
Hay	70 million tons
Apples	253 ,, bushels
Peaches	54 ,, ,,

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m. :—

January 19. — Lawrence Chubb, "The Common Lands of London: the Story of their Preservation." Lord Farrer will preside.

January 26.—J. Arthur Hutton, Chairman of the British Cotton Growing Association, "The Effect of the War on Cotton Growing in the British Empire."

February 2.—S. Charles Phillips, M.S.C.I., "Paper Supplies as affected by the War."

February 9.—Professor J. A. Fleming, M.A., D.Sc., F.R.S., "The Organisation of Scientific Research." Dugald Clerk, D.Sc., F.R.S., Chairman of the Council, will preside.

February 16.—The Hon. Lady Parsons, "Women's Work during and after the War."

February 23.—Miss H. B. Hanson, M.D., B.S., D.P.H., "Experiences in Serbia."

Indian Section.

January 13. — Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., late Survey of India, "The Romance of the Indian Ordnance Survey." Dugald Clerk, D.Sc., F.R.S., Chairman of the Council, will preside.

February 17.—C. A. Kincaid, C.V.O., Indian Civil Service (author of "Deccan Nursery Tales," "The Indian Heroes," "The Tale of a Tulsi Plant," etc.), "The Saints of Pandharpur." Lieut.-Colonel Sir David W. K. Barr, K.C.S.I., will preside.

March 16.—Professor Wyndham R. Dunstan, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India."

Dates to be hereafter announced :—

R. W. Seton-Watson, D.Litt., "The Balkan Problem."

Charles R. Darling, A.R.C.Sc.I., F.I.C., "Optical Appliances in Warfare."

Rev. P. H. Ditchfield, "The England of Shakespeare."

W. A. Craigie, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

Victor Horta, Directeur de l'Académie Royale des Beaux-Arts de la Ville de Bruxelles, "Belgian Architecture."

Charles Delchevalerie, "Belgian Literature."

Professor T. G. Masaryk, "The Slavonic Peoples."

G. P. Baker, "Hindu Hand-painted Calicoes of the Seventeenth and Eighteenth Centuries, and their Influence on the Tinctorial Arts of Europe."

Sir Daniel Morris, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland."

James MacKenna, M.A., I.C.S. (Deputy Commissioner, Myaungmyn, Burma, and designated Agricultural Adviser to the Government of India), "Scientific Agriculture in India."

Indian Section.

Thursday afternoons at 4.30 p.m. :—

April 6, May 18.

Colonial Section.

Tuesday afternoons, at 4.30 p.m. :—

February 1, March 7, May 2.

Cantor Lectures.

Monday afternoons at 4.30 p.m. :—

J. Erskine-Murray, D.Sc., F.R.S.E., M.I.E.E., "Vibrations, Waves, and Resonance." Four Lectures.

May 1, 8, 15, 22.

Fothergill Lectures.

Monday afternoons, at 4.30 p.m. :—

Rev. Dr. Herbert West, D.D., A.R.I.B.A. (author of "Gothic Architecture in England and France"), "Flemish Architecture." Three Lectures.

February 7, 14, 21.

Edward A. Reeves, F.R.A.S., Map Curator, Royal Geographical Society, "Surveying." Three Lectures.

March 27, April 3, 10.

Juvenile Lectures.

These Lectures will be given on Wednesday afternoons, January 5 and 12, at 3 p.m. The first lecture will be given by Professor John Millar Thomson, LL.D., F.R.S., on "Crystallisation," and the second by Mr. James Swinburne, F.R.S., on "Science of some Toys."

Journal of the Royal Society of Arts.

No. 3,293. VOL. LXIV.

FRIDAY, DECEMBER 31, 1915.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 5th, 3 p.m. (Juvenile Lecture.) PROFESSOR JOHN M. THOMSON, LL.D., F.R.S., "Crystallisation."

The lecture will be fully illustrated with numerous experiments.

Special tickets are required for these lectures, and no person can be admitted without a ticket. A few tickets are still left, and these will be issued to Fellows who apply for them at once.

Further particulars of the Society's meetings will be found at the end of this number.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s.* 6*d.* each, on application to the Secretary.

THE ORIGIN OF ENGLISH MEASURES OF LENGTH.

By COLONEL SIR CHARLES M. WATSON, K.C.M.G., C.B., R.E.

Although there is considerable variety in the measures of length used by the different nations of the world, there can be no doubt that they are, for the most part, derived from a common origin, and that their ancestors, if the expression may be used, existed in times so remote that the date of their invention has been completely lost. But the study of what the original measures were is a matter of considerable historical importance, and the question can be investigated by an examination of the changes made in the course of generations by the people who have adopted them—changes, in some cases, apparently due to accident rather than design.

For the sake of clearness, it is convenient to divide the measures of length into four categ ories which are, to a certain extent, independent of one another, and may be defined as follows:—

(1) The shorter measures of length, used for building and manufacturing purposes, of which the more important in ancient times were the cubit, the palm, and the digit, or finger breadth, and the English representatives are the yard, the foot, and the inch. (2) The shorter measures of distance, such as the foot, the yard, and the pace. (3) The longer measures of distance, including the stadium, the mile, the parasang, the schoenos, the league, the hour's march, and the day's march. (4) Measures of length used in connection with the calculation of land areas, of which the English representatives are the perch, the chain, and the furlong.

As regards the first of these classes of measures, it is generally accepted that they were, from the earliest times, based on the proportions of the human body, so that every man had his own scale to which he could work. As, however, men are not all of the same size, there is considerable variety in the length of the different units, but, with some exceptions, they may be included within the following limits:—

The digit (or finger breadth)	from 0·72 to 0·75	English in.
The palm,	,, 2·88 to 3·00	,, inches.
The cubit,	,, 17·28 to 18·00	,, ,,
The fathom,	,, 5·50 to 6·00	English ft.

The palm is the width across the open hand at the base of the fingers; the cubit is the length of the arm from the elbow to the end of the middle finger; and the fathom the length of the outstretched arms. There is no fixed relationship between these units.

There is no record as to when an attempt was first made to combine the measures in a standard scale, but it was probably at an early period, as it must have been found inconvenient for workers on the same building, for example, to use different lengths of palms and cubits, and, when a standard was fixed, it may have been some such scale as the following:—

1 digit =	0·7375	English inch.
4 digits = 1 palm =	2·95	,, inches.
6 palms = 1 cubit =	17·70	,, ,,

The cubit of this scale may be called the "cubit of a man," to distinguish it from other cubits, which will be described hereafter.

In process of time it was found desirable to have a smaller unit than the digit, and this was made by taking it as equal to six grains of barley placed side by side. In the English scale, barleycorns were also used as the smallest measure of length, but in this case they were placed end to end, three barleycorns so placed being taken as equal to one inch.

There is no evidence that the foot was included originally among the units of the hand worker given above, and it may, perhaps, more properly be regarded as belonging to the second class of measures, derived from the distance covered by a man walking, and as a subdivision of the important unit, the pace. The pace is of two kinds, the first being the single pace, or distance covered by the step of one foot, and the second, the double pace, the distance covered by both feet one after the other.

In the case of the Roman double pace, a very important measure, the pace was taken as equal to five feet, but this was an artificial connection, as there is no fixed proportion between the length of a man's foot and the length of his pace.

There is nothing to show when the foot was added to the units of the mechanic's scale, but when this was done it was assumed to be equal to four palms, or two-thirds of a cubit.

The third class of measures of length is the most important, and the history of these is of particular interest, as they appear to have started in a state of perfection, and to have been first used by a people who possessed a high degree of astronomical and mathematical knowledge, who were acquainted with the form of the earth, and were able to carry out accurate geodetical measurements. It is also remarkable that the changes made as regards these measures in the course of time have been changes for the worse, in consequence, apparently, of the origin of the measures having been forgotten. There can be no doubt that they are based on the angular division of the circle, and on the application of this division to terrestrial measurements.

The unit of angular measurement is the angle of an equilateral triangle, and this angle was divided by the ancient geometricians, for purposes of calculation, into 60°, the best number possible, as $60 = 3 \times 4 \times 5$. Following the same principle, each degree was divided into 60 minutes, and each minute into 60 seconds. As the circle contains six times the angle of an equilateral triangle the circle was divided into 360°. This division of the circle, although so ancient that its origin is unknown, has never been improved upon, and is still in use by all nations. An attempt on the part of certain French mathematicians to substitute a division of the circle into 400°, on account of the supposed advantages of the decimal system, has proved a failure.

The manner in which the division of the circle into 360° was used by the ancients to determine the unit for terrestrial measures of distance was as follows. If a circle be described cutting the equator of the earth at right angles, and passing through the north and south poles, its circumference in angular measurement is equal to $360° \times 60' = 21{,}600'$, and the length of 1 minute, measured on the surface of the globe, was taken as the unit, which is called a geographical mile at the present time. If the earth was a perfect sphere, every geographical mile would be of the same length, but, as the polar diameter is less than the equatorial diameter in the proportion of 7,900 to 7,926, the length of the geographical mile, measured on the meridian, is not the same in all latitudes, but increases in length from 6,046 English feet at the equator to 6,108 English feet at the poles. Whether the ancient astronomers were acquainted with this irregularity in the figure of the earth it is not possible to say, but it is certain that the value at which they fixed it must have been close to the actual mean value as determined by modern astronomers, which may be taken as about 6,075 English feet. The Greek stadion (the same as the Roman stadium), which was one tenth of the geographical mile, was 600 Greek feet in length, and the Greek foot was about 12·15 of our present English inches.

The next step taken appears to have been with the view of assimilating the subdivisions of the geographical mile with the cubit, and it was not easy to do this, as the cubit of a man has no necessary connection with a geographical mile. The difficulty appears to have been solved by the invention of two new cubits, of which the smaller was very nearly equal to the cubit of a man, and was contained 4,000 times in the geographical mile. This, for the sake of distinction, may be called the geographical cubit. The second cubit, afterwards known as the Babylonian Royal cubit, was longer, and was contained 3,600 times in the geographical mile. According to Herodotus this second cubit was three digits longer than the other cubit. On these two cubits there appear to have been based two different divisions of the geographical mile, one in accordance with a decimal, and the other with a sexagesimal system of calculation, but there is, so far as I know, no ancient record of these scales, and the following attempt to compose them is founded on inferences, drawn from the Babylonian, Greek and Roman measures, all of which, there can be little doubt, came from the same origin.

The first, based on the geographical cubit, which was rather longer than the average cubit of a man, is as follows:—

	1 digit	= 0·729	English inch.
25 digits	= 1 geographical cubit	= 18·225	„ inches.
100 „	= 1 fathom	= 6·075	English feet.
100 fathoms	= 1 stadion	= 607·5	„ „
10 stadia	= 1 geographical mile	= 6075	„ „

The second, or sexagesimal scale, based on the Babylonian Royal cubit, appears to have been as follows:—

	1 digit	= 0·723	English inch.
28 digits	=1 Royal cubit	= 20·25	„ inches.
60 cubits	=1 plethron	=101·25	English feet.
60 plethra	=1 geographical mile	= 6075	„ „

Some writers are of opinion that the Babylonian Royal cubit was composed of 30 instead of 28 digits, but this appears to be improbable, because it would make the digit too small, and, if Herodotus is correct, it would make the cubit in the decimal scale consist of 27 digits, an inconvenient number. Nor is there any evidence to prove that a cubit was ever divided into 27 digits, while Professor Petrie has shown, in "Inductive Metrology," that the division of the cubit into 25 digits, and of the fathom into 100 digits, is very probable. There was another Babylonian measure of length called the gar, used for land measurements, which appears to have been composed of 12 Royal cubits. It was the ancestor of the English land measure, the perch, which is 11 English cubits in length.

The ancient Egyptian measures of length, although evidently derived from the same origin as the Babylonian, differ from these in some respects. The most important smaller unit was a cubit usually known as the Egyptian Royal cubit, which was divided into seven palms, each palm of four digits. The approximate length of the Egyptian Royal cubit is well known, as a number of cubit scales have been found which give a mean length of 20·65 English inches, and an examination of the monuments of Egypt shows that this cubit was used for building purposes from ancient times.

Professor Petrie, in "Inductive Metrology," has given a large number of samples of the Egyptian cubit derived from the measurements of buildings, which vary from 20·42 to 20·84 English inches, and yield a mean value of 20·64 English inches, or almost exactly the same as the mean length of the cubit scales.

As is generally the case with regard to measures of length in all countries, the Egyptian cubit appears to have grown longer in course of time, and there is a good instance of this shown by a comparison of the three nilometers on the island of Philæ, above Assuan, of which the first gives a mean value for the cubit of 20·47 English inches, the second of 20·81, and the third of 21·05 English inches.

The best results given by Petrie are based on his measurements of the Great Pyramid of Gizeh, the great chamber of which, having a length of 20 cubits and a width of 10 cubits, yields a cubit of 20·627 English inches, while the height of 78 palms gives a cubit of 20·65 English inches. The length of the side of the base of this pyramid is of particular interest, as it appears to have been designed as one-eighth of a geographical mile. This length is not easy to measure, as the lower part of the pyramid is covered with sand and rubbish, and the stones which cased it have been removed. Petrie, after very careful measurement, arrived at the conclusion that it was 755·7 English feet. There are reasons for thinking it may have been a little more than this, but less than 760 feet. The length of a geographical mile at the latitude of the pyramid is 6,060 feet, and one-eighth of this is 757·5 feet, or so nearly equal to the length of the side of the base that it is difficult to believe that the architect had not this in view when he designed the pyramid. The side of the base was therefore equal to 500 geographical cubits, and very nearly equal to 440 Egyptian Royal cubits—a remarkable coincidence, if it is only a coincidence. It is interesting to note that there are 440 English cubits in the English furlong, but whether this has any connection with the measure of the pyramid there is no evidence to show.

There was a good reason for making the side of the base 440 cubits, as the height is equal to the radius of a circle, of which the perimeter of the base is the circumference, so that the height was 40×7 cubits, and the length of the side 40×11 cubits. It would be interesting to know how the ancient Egyptian geometrician arrived at so close an approximation to the value of π as $\frac{22}{7}$.

It is matter of controversy from whence the Greeks derived their measures of length, whether from Egypt or Babylonia; but the latter appears more probable, as their principal measure of distance, the stadion, was equal to one-tenth of a geographical mile of 6,075 English feet, and this was divided into 6 plethra, each of 100 Greek feet. The Greek scale appears to have been as follows:—

	1 Greek foot	= 12·15	English inches.
$1\frac{1}{2}$ Greek ft.	=1 cubit	= 18·225	„ „
10 „ „	=1 reed	= 10·125	English feet.
10 reeds	=1 plethron	=101·25	„ „
6 plethra	=1 stadion	=607·50	„ „
10 stadia	=1 geographical mile	= 6,075	„ „

There was another foot used in Greece, of which Petrie gives a number of instances, derived from old buildings, varying from 11·43 to 11·74, with a mean value of 11·60 English inches. This would appear to be a foot of 16 digits, used for building and manufactures, but not connected with measures of distance.

The Roman system of measures was based on the Greek, but while adopting the stadion—called by them stadium—as the fundamental measure of distance, they used the shorter Greek foot, and introduced another measure, the double pace. They also made the land mile to consist of 8 instead of 10 stadia, while retaining the geographical mile of 10 stadia for use at sea. As they had an affection for a duodecimal system of calculation, they also divided the foot into 12 inches, in addition to the old division into 16 digits. The Roman scale, which showed considerable ingenuity in assimilating a number of different measures

which had no real relationship to one another, appears to have been as follows:—

		1 digit	= 0·729	English inch.
		1 inch	= 0·972	,, ,,
4 digits or 3 in.	=	1 palm	= 2·916	,, inches.
4 palms	=	1 foot	= 11·664	,, ,,
6 ,,	=	1 cubit	= 17·496	,, ,,
5 feet	=	1 pace	= 4·86	English feet.
125 paces	=	1 stadion	= 607·5	,, ,,
8 stadia	=	1 land mile	= 4,860	,, ,,
10 ,,	=	1 geographical, or sea mile	= 6,075	,, ,,

The land mile was probably made up of 8 stadia in order to have it exactly 1,000 paces in length, or it may have been considered that eight was a more convenient number for dividing than ten; but it was necessary to retain the mile of 10 stadia for navigation.

The above remarks deal with the measures of distance used by the principal nations of antiquity up to and including the geographical mile, upon which they seem to have been based, but in addition to these there are certain longer measures of distance which must be referred to, such as the parasang, the schoenos, and the league. The fundamental idea of these measures was that they represented the distance which could be marched in a given time, such as one hour, and as the rate of marching naturally varied with the nature of the country, it was not easy to have a fixed length, and when there was made a theoretical unit it did not always agree with the actual distance.

There is a good example of this in the "Anabasis" of Xenophon, in which the writer recorded the distance travelled by the Greek force, day by day, on their way across Asia Minor from Ephesus to the Euphrates, and, after the battle of Cunaxa, from the Euphrates to the Black Sea. Xenophon gives the distance from Ephesus to the battlefield as 535 parasangs, or 16,050 stadia, thus making the parasang equal to 30 stadia, or 3 geographical miles. But Colonel Chesney has pointed out that the actual parasang, or hour's march, was less than this, and that it averaged 26 stadia from Sardis to Thapsacus, and about 20 stadia from Thapsacus to the battlefield of Cunaxa. A fair average hour's march for an army would be 25 stadia or 24 stadia, equal to 3 Roman miles, and a day's march of eight hours to 20 geographical or 24 Roman miles. In the Antonine Itineraries the distance between important stations is, in a number of cases, given as 24 and 25 Roman miles, which looks as if the stations were fixed at distances apart suitable for a day's march.

In Egypt the measure of distance corresponding to the parasang was the "ater," called "schoenos" by the Greeks, and stated by different writers to have been equal to 30, 32, 40, and 60 stadia in various parts of Egypt. It is evident that it was based on the geographical mile as a rule, while 32 stadia is equal to four Roman miles. There is some doubt whether the Egyptians had a fixed length for the schoenos, and a good deal has been written with regard to it, notably a paper entitled "Der Schoinos bei den Aegyptern, Griechen und Römern," by Wilhelm Schwarz, published at Berlin, 1894.

Another longer measure of distance, which was largely used in the western parts of Europe under the Roman Empire was the Gallic league, equal to 12 stadia or one and a half Roman miles. In the Antonine Itineraries the distances in Gaul are in some cases given in leagues, and in others in both leagues and Roman miles, while, in the "Bordeaux Pilgrim," a work dating from the early part of the fourth century, the distances in the west of France are given in leagues, and afterwards in Roman miles.

An important application of measures of distance from the earliest times was for the calculation of areas of land, but there is considerable doubt as to what was the original unit, and whether this was a square, or in the form of a rectangle one stadium in length and one-tenth of a stadium in width. In the latter case there would have been ten measures in a square stadium, and 1,000 measures in a square geographical mile, and such a measure would seem quite in accord with the ancient system of measures of distance. Its area would have been 40 × 400 geographical cubits (36 × 360 Babylonian Royal cubits), or 0·847 English statute acre. There is a very widely distributed type of land measures based on a rectangle of this form, of which the English acre is an instance, as it measures 44 × 440 English cubits.

The Egyptian unit of land area appears to have been the "set," called "arura" by the Greeks, which was a square having a side of 100 Egyptian Royal cubits. A cubit of land was the $\frac{1}{100}$ part of this, and was the area of a rectangle 1 × 100 cubits.

In the Greek system the unit of area was the square of a plethron or 100 Greek feet, equal to 0·235 English acre, of which there were 36 in a square stadion and 3,600 in a square geographical mile.

The Roman unit of land area, called the "jugerum," was a rectangle, 120 × 240 Roman ft., or 0·624 English acre, which was subdivided duodecimally, the uncia of land being the twelfth part of a jugerum, or the area of a rectangle measuring 10 × 240 Roman feet. The relative proportions of these different units of land area were as given on page 129.

It will be seen from the above descriptions that from the earliest times the shorter measures of length were based on the proportions of the human body, and the longer on the geographical mile, and that at some remote period an attempt was made to combine them into a continuous scale, from the digit to the geographical mile. When the digit was made the point of departure the decimal system of calculation appears to have been preferred, and when the scale was worked downwards from the mile the sexagesimal system was the most convenient, while in the Roman scale the

Area of Unit.	Number contained in Geographical Miles.	Area in English Statute Acres.
36 × 360 Babylonian Royal cubits	1,000	0·847
100 × 100 Greek feet	3,600	0·235
120 × 240 Roman feet	1,356	0·624
100 × 100 Egyptian Royal cubits	1,240	0·683
Geographical square mile	1	847·238
English square mile	1·324	640

duodecimal system was introduced. But it is to be regretted that the more ancient system was not retained, by which the geographical mile was the unit, and was divided into 10 stadia, each of 400 cubits, or 600 feet, as it is doubtful whether the changes made by succeeding generations can be regarded as improvements.

The modern measures of the civilised world are, with few exceptions, based on the ancient units, of which they may be regarded as the direct descendants. Of these exceptions the most important are the measures of the metric system, which were designed with the object of breaking away from the records of the past by the adoption of a new geographical mile, equal to $\frac{54}{100}$ of the true geographical mile.

The English measures of length are a good example of the modern representatives of the old units, and are worthy of study from this point of view. How the measures originally came to England it is not easy to say, but there can be no doubt that they were in use before the Roman invasion, having possibly been introduced by Phœnician traders, and were afterwards modified by the Romans, the Saxons, the Scandinavians, and the Normans, each of whom had measures, based on the old units, but altered in course of time. It was not until the thirteenth century that they were moulded by law into one uniform system.

The English scale, as authorised by statute, may be summarised as follows:—

	1 inch.
12 inches	= 1 foot.
3 feet	= 1 yard.
5½ yards	= 1 rod, pole, or perch.
4 perches	= 1 chain.
10 chains	= 1 furlong.
8 furlongs	= 1 English statute mile.

Of these units the inch is derived from the Roman system, being one-twelfth of the foot, but the foot, on the other hand, is equal approximately to the Greek foot, while the yard, which is simply a double cubit, comes from the Babylonian system, being approximately a double geographical cubit. The perch is the English representative of the Babylonian gar, and the furlong occupies a similar place to the stadium, while the mile is composed of eight stadia, apparently in imitation of the division of the Roman mile. For use at sea, however, the geographical mile, divided into ten stadia, or, as we call them, cable lengths, has been retained, as no other mile can be used for purposes of navigation.

In order fully to understand the connection between the English measures and the ancient measures of length, it is necessary to write the scale in a somewhat different manner, and to introduce some other units which are no longer used. The revised scale is as follows:—

	1 barleycorn.
3 barleycorns	= 1 inch.
3 inches	= 1 palm.
4 palms	= 1 foot.
6 ,,	= 1 cubit.
12 ,,	= 1 double cubit or yard.
11 cubits	= 1 perch.
405 ,,	= 1 cable's length.
4 perches	= 1 acre's breadth or chain.
10 chains	= 1 acre's length or furlong.
8 furlongs	= 1 English mile.
10 cables	= 1 geographical, or sea mile.

The English inch is equal in length to 3 barleycorns set end to end, or to the width of 8 barleycorns, set side by side. The barleycorn, as a measure, is forgotten, but the inch on carpenters' rulers is still divided into eight parts, while, on a shoemaker's tape, the sizes of boots and shoes increase by a barleycorn, or ⅓ inch, for every size. For example: size No. 8 of a man's boot measures 11 inches; size No. 9, 11⅓ inches; size No. 10, 11⅔ inches, and so on. One would have thought that the sizes would increase by one quarter of an inch at a time, but the barleycorn has held its place to the present day.

The palm, which was originally composed of 4 digits or finger breadths, and, since the time of the Romans, of 3 inches or thumb breadths, is no longer used in England, and its place has to a certain extent been taken by a measure called the hand, composed of 4 inches and employed in measuring the height of horses. The change may have been due to the fact that the number 4 was more convenient for division than 3, and that when the digit gave way to the inch the palm of 4 digits was replaced by the hand of 4 inches.

Prior to the thirteenth century, the length of the foot in England was uncertain, and there appear to have been several measures in use, varying from the Roman foot of 11·66 English inches to the Belgic foot of 13·12 English inches; but, by the Ordinance known as the Statute for Measuring Land, enacted in the reign of King Henry III., the relations of the inch, the foot, and the cubit to one another were definitely fixed, and have never since been altered. The cubit of this Statute is the double cubit, afterwards called the yard. A translation of the Latin words of the Statute, describing the different measures, is as follows:—

"It is ordained that 3 grains of barley, dry and round, make an inch; 12 inches make a foot; 3 feet make a cubit; 5½ cubits make a perch; 40 perches in length and 4 perches in breadth make an acre.

"And it is to be remembered that the iron cubit of our Lord the King contains 3 feet and no more; and the foot must contain 12 inches, measured by the correct measure of this kind of cubit; that is to say, one thirty-sixth part of the said cubit makes one inch, neither more nor less. And 5½ cubits, or 16½ feet, make one perch, in accordance with the above-described iron cubit of our Lord the King."

It is interesting that, in this Statute, the double cubit, thus accurately described, should have been called the cubit of the King, just as the longer cubits of Babylon and of Egypt were called Royal cubits to distinguish them from the shorter cubits of those countries. In the Latin original of the Ordinance the word used is "ulna," the usual word for cubit. The word "yard," to signify the English double cubit, occurs for the first time in the laws of England in a Statute of 1483, which is written in French.

The perch, equal to 11 single or 5½ double cubits, is a very ancient measure, but I cannot find at what period it was first used in England. It was employed principally in connection with the measurement of land, and I have already pointed out its likeness to the Babylonian measure the gar, which was composed of 12 Babylonian cubits.

The two measures, the acre's breadth, afterwards called the chain, and the acre's length or furlong, have also been used from a very early period. The former is equal to 44 single cubits, 22 yards, or 66 English feet, while the latter is exactly ten times this, 440 cubits, 220 yards, or 660 feet. The furlong is the modern representative in our system of the ancient stadium, which had a length of 600 Greek feet, or 607·5 English feet, but the reason for its being longer than the stadium has, so far as I know, not been satisfactorily explained. But the change may have been due to the fact that other measures of distance were in use in England prior to the present statute mile, which varied in different parts of the country, and the mean of these was approximately equal to the Gallic league of 12 stadia or 7,290 English feet. One-eleventh of this, 663 English feet, is approximately equal to the English furlong, and eight of these measures, following the Roman system, were combined to form the English statute mile.

But whether this is the origin or not, there appears little doubt that the mile, furlong, and chain, or acre's breadth, were in use in England in Anglo-Saxon times, as there is a law of King Athelstane, who reigned A.D. 925-940, in which it is enacted:—

"Thus far shall be the King's grith from his burgh gate where he is dwelling, on its four sides; that is three miles, and three furlongs, and three acre's breadths, and nine feet, and nine palms, and nine barleycorns."

The length of the measure called the King's grith, or King's peace, was the distance from his house within which peace was to be maintained, and it is evident that in this law an attempt was made to express the distance in terms of ordinary measures. Converting these terms into feet we have:—

3 miles	= 3 ×	5,280 feet	=	15,840 feet.
3 furlongs	= 3 ×	660 „	=	1,980 „
3 acre's breadths	= 3 ×	66 „	=	198 „
9 feet	=	9 „	=	9 „
9 palms	=	2¼ „	=	2¼ „
9 barleycorns	=	¼ foot	=	¼ foot.
		Total	=	18,029½ feet.

18,029½ = 601 × 30 very nearly, so that it would appear that the length of the King's grith was 30 stadia, the same measure as that known in the East as the parasang, and in Egypt as the schoenos. It is remarkable that this measure should thus appear to have found its way to England, and there be regarded as a Royal measure.

There was another measure of distance used in England, known as the leuga, composed of 12 furlongs, which corresponded to the Gallic league of 12 stadia already described. In the Chronicles of Battle Abbey, which extend over the period A.D. 1066-1176, in the account of the lands belonging to the abbey, the following statement occurs: "The English leuga contains 12 roods (furlongs), and 40 perches make one rood; the perch is 16 feet in length; the acre is 40 perches in length and 4 in breadth; but if it is 20 perches in length, it shall be 8 in breadth." The acre's length, here called rood, and the acre's breadth appear to have been the same as in the time of King Athelstane, and the foot is the Saxon foot, equal to 12·375 of our present inches. The measurement of the acre, 4×40 perches, is the same as that given in the Statute for Measuring Land enacted in the reign of King Henry III., which has already been referred to.

The terms acre's length and rood are no longer used, and this measure is now known as the furlong, while the acre's breadth has been called the chain since the beginning of the seventeenth century, when it was divided into 100 links instead of 66 feet. The chain, which was the invention

of Professor Gunter, has proved very convenient for the measurement of land acres, and is now always used.

Since the introduction of the chain, the perch or rod has been less employed in connection with land measures, but is still used by builders for the measurement of brickwork. The common English stock brick is half a cubit in length, one quarter of a cubit in width, and one-sixth of a cubit in thickness, or rather less than these dimensions, to allow for the thickness of the mortar joints, while a rod of brickwork, which is the unit for builders' work, is a mass of brickwork, one rod or 22 bricks in length, one rod or 66 bricks in height, and three bricks in thickness. The perch or rod of brickwork contains 4,356 bricks.

The English sea mile is exactly the same as the geographical mile of the Babylonian system, and its tenth part, the cable length, is identical with the stadium. In these measures there has been no change, and the only difference is that the cable length is 405 English cubits, whereas the stadium was 400 original cubits. This is due to the fact that the English cubit is a little shorter than the latter in consequence of the English foot, as fixed by law, being rather less than $\frac{1}{6000}$ part of the geographical mile.

It will be seen from the above *résumé* that our English measures of length are no haphazard modern invention, as some people imagine, but have come down to us from prehistoric times. They have proved most convenient for the different uses to which they are applied, and it is to be hoped that they will never be abandoned in favour of the metric measures, notwithstanding the pertinacity with which the advocates of the latter press their views on the public. Such a change would do England no good, but would considerably assist foreign manufacturers; and there can be little doubt that the agitation in favour of the metric system has been pushed by German agents in this country, as they are fully aware that it would be for the advantage of German trade and assist in that capture of the world's commerce for which Germany has been working for many years. Possibly one effect of the present war may be to put an end to the attempt to abolish our English measures in order to compel Englishmen, against their will, to adopt those of the metric system.

DROUGHT-RESISTING GRASS SEEDS IN SOUTH AFRICA.

In the course of an article entitled "Notes on some Effects of Extreme Drought in Waterberg, South Africa," which appeared in the Agricultural Journal of the Union of South Africa, and is reprinted in the annual report of the Smithsonian Institution, Mr. Eugène N. Marais gives an interesting account of the way in which the seeds of certain coarse, rank, and "sour" grasses have adapted themselves to resist the droughts which are becoming more frequent and of greater intensity in the Waterberg district.

The life history of these seeds, he says, is one of those fairy tales of botany that might be of interest even to the busy man who has no time to notice. With a body shaped like a torpedo, and a long tapering tail, they have attained in perfection the tadpole shape, which Nature finds of such advantage that she has evolved it a thousandfold in the highest and lowest forms of life—indeed, it is probable that from such a shape have all organic forms originated. Under low magnification it will be seen that both body and tail are thickly studded with sharp, stiff bristles growing backward. The point of the torpedo is an intensely hard, horny spike, sharp as the point of a needle, with a coronal of harpoon points at its base. The seed is thus able to cling to the coats of animals, besides being easily moved off by the wind. But these qualities are of more immediate value in another direction. It is above all things a penetrating machine—how efficient one can judge from the fact that it is often found in the internal tissues of animals, having gone through coat, muscle, and flesh. It often penetrates human flesh, and is then always a source of serious danger. Every movement, however slight, causes the embedded seed to penetrate deeper, and frequently a serious operation only can remove it.

But it was not for this purpose only that its penetrative qualities were evolved. It is a common thing in good rain years to come across a mass of these seeds drifted together by the wind. It is then that one has an opportunity of seeing a wonder of plant life quite startling in the apparent intelligence disclosed. The seeds as they lie are huddled and orderless, like casually thrown spillikins. If one sprinkle a little water on the mass a tremor as of awakening life is almost immediately seen to pass through them. Movements in all directions follow—spasmodic jerks, twistings, and turnings so animal-like as almost to leave one in doubt whether they veritably are seeds and not insects. And this doubt intensifies as the process continues and the purpose becomes more apparent. One sees that by these movements the seeds are disentangling themselves, and when this is effected each one becomes engaged in independent movements. At first it all seems erratic and casual, and it is only after careful watching that it dawns upon one that all these movements are quite ordered, and have a definite purpose. The first spring-like twistings lift the seedhead clear off the ground and free it from obstructing fellows. A bend of the tail, on which it then rests, turns the torpedo-head point earthwards. It is gradually lowered until the needle-point, with its harpoon bristles, is thrust into the damp soil with a steady and continuous pressure from the tail. This movement is continued until the entire seed is embedded, the whole operation lasting fifteen minutes. But its chief protection against drought, and the accompanying ineffective and, in fact, fatal night-showers lies herein, that if the soil be only slightly damped the seed penetrates

beyond the line of moisture, and remains thus without germinating, ready planted, waiting for enough rain to ensure the safety of the future seedling. This penetration is proportionate to the length of tail, and it will be found at the end of a season of severe drought that the species with the longest-tailed seeds have started more seedlings than the relatively short-tailed. The hard shells of these seeds also require a definite and large amount of moisture to soften.

MANUFACTURE OF PAPER FROM SUGAR-CANE BAGASSE.

The manufacture of paper from sugar-cane bagasse has been repeatedly attempted in Cuba, and the final results can be estimated from the following particulars extracted from a recent report by the Canadian Acting Trade Commissioner at Havana.

In conjunction with the making of sugar from cane at Preston, another important industry is being conducted successfully in the manufacturing of wrapping paper from the by-product of sugar-cane bagasse or pulp. The mill has now been in operation for a period of ten months, and in the earlier stages was only operated as an experiment. The work was started in connection with, and under the direction of, the Wisconsin University Laboratories, where the original tests and experimental work were carried on, and the plant at Preston is now in charge of the graduates of this institution. A staff of twenty-five men is now employed in the mill, and four tons of paper is the daily output. The facilities and machinery at present provide only for the manufacture of several grades and weights of wrapping paper. Arrangements are now under way, and the required machinery will be added, for the manufacture of all grades of paper. The pulp runs about two tons to one of paper.

The buildings are of a sheet-metal construction, and are fireproof. In the main building three elevations of the floors are used in transferring the pulp to paper. The process of manufacture is as follows:—

The bagasse is carried from the sugar-mill in cars to the paper-mill, and then conveyed to the top floor of the paper factory. From there it is shovelled to the floor below into "digester" tanks, where it is digested or boiled by live steam. The only difference noticeable to a layman between the manufacture of bagasse paper and that of wood-pulp paper is the process of digestion or boiling in order to soften the stock to the desired point at which it can be beaten, and this digesting takes the place of grinding up the wood. The bagasse is transferred from the digesters to the beaters and beaten into pulp, when chloride of lime is added to the pulp in the beaters (of which there are four), and when beaten to a sufficient consistency is dropped in pipes to retaining tanks on the floor below. From the retaining tanks the pulp is carried to the paper-mill or machine, where a quantity of water is added to it to get the thin solution. This thin solution is run over a wire screen, and all the water is extracted by means of suction. The paper is then dried on the usual steam drums of a paper-mill.

Three weights of wrapping paper are manufactured, of which the highest is 80 lb. In the case of making paper from cane bagasse, the necessary grinding is done at the mill in the production of sugar, which eliminates this process of manufacture at the paper-mill. The paper obtained from cane pulp is equal to, if not slightly better than, the paper manufactured from imported kraft stock, and it can be produced and marketed at a price considerably lower than that quoted for kraft paper. Samples of the paper show various colours, and a considerable degree of strength. The output is sold in Cuba for local consumption.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Government Requisitions.—The commandeering by the Government of about half the production of Dundee jute goods during the next three months is a repetition of an experiment previously made in the same quarter. It can be assumed, therefore, that, from the Government point of view, the issue of the experiment has been successful. The requisitioning of machinery operates, of course, in favour of promptness in delivery, and the fixing of prices as between spinners and manufacturers, and again between manufacturers and the purchasing department, at least puts limits to the hoist of prices. The policy would appear to have secured supplies at handsomely lower rates than were, or are, asked of private traders, and that aspect of the matter has a wider interest. Men concerned in other textile markets have been asking whether it might not have been better had the Government taken the same course in regard of other commodities that have been forced up in price by the demand for military clothing. That it would have been better for the Government on the score of economy is freely assumed. Some traders, at all events, are disposed to think it would have been better also for themselves, and would have moderated prices in the regular market. Circumstances alter cases, but so far as Dundee evidence goes, the residue remaining after Government requirements had been filled would still have been susceptible of increase in price.

Cotton Trade Losses.—The extra cost of bringing raw cotton from America to Lancashire is estimated roundly at one penny per lb.: a formidable charge upon a 7½*d.* article. Fuel for the mills costs 40 per cent. more, leather 50 per cent., oil and repairs 20 per cent., cartage

10 per cent., and labour 5 per cent. more than they did in time of peace. These charges, uncompensated by gains in efficiency, or in the purchasing power of the principal markets, and only imperfectly balanced by corresponding increases in the costs of competitive work in some neutral countries, are of a mischievousness difficult to exaggerate. They go to explain more than loss of profit, and would render worse records than Mr. Kidger's intelligible. In his annual financial statement of the progress of one hundred Oldham cotton-spinning mills, he shows that on a capital of slightly over £3,500,000 the aggregate loss was £15,000. Forty-two companies made profits, and they were either ring-spinning mills or producers of coarse counts. It is significant of how war turns everything about that the mills to do best should be those equipped with spindles of a type used more abroad than at home, and mills producing the thick yarns that have been left so generally to the foreign spinner. It happens that these yarns have been needed for the purposes of war, and the profits have gone to those in a position to take up the business. With the aid of their reserves the hundred companies have distributed an average dividend of 5 per cent., and the payment of it is one sign of a hope of better days in store for what is in effect a reduced industry. The absorption of men into the Army, by curtailing production, achieves much the same result as the organised short-time working which is the normal remedy for low margins.

British Dyes.—Impressively large extensions have been made to the nucleus works of British Dyes Ltd., at Huddersfield, and these in turn are small beside the great development which has been staked out. The extensions have not yet come into bearing, and upon the part of the best informed persons there is little disposition to encourage sanguine hopes of a larger supply of dyestuffs during the continuance of the war. The materials, the chemicals, and much of the plant wanted for colour-making are still more urgently wanted for high explosives, and those most in need of more dyes put munitions first. The present output of the works at Huddersfield is allotted entirely to consumers in ratio to their holding of shares in the company. The receipts by any one shareholder are far below his actual needs, but he gets a limited supply of what corresponds to water in a desert at prices controlled by the cost of production. He pays about twice as much as formerly for dyestuffs, for which dealers ask ten or twenty times the old rates, and on the strength of these is able to undertake profitable business which has otherwise to be refused. There are no opportunities at present of embarking on the production of new coal-tar colours, but the time for that departure is coming. Meanwhile, a certain number of goods are being dyed with anilines resurrected from odd corners, and to which neither the user nor the seller can attach a name. The dyed product is sold under the now familiar intimation that the fastness of colours cannot be guaranteed. This disclaimer lifts a load off the dyer's back, and it is apparent that there are dyers now making far more money out of dear dyestuffs than ever they did out of cheap.

Logwood.—The absence of the tar colours has been made tolerable by the presence of the vegetable extracts and chiefly of logwood, on which a new dependence has been placed. Serious fears of a shortage of the supply of logs, dust or haematin crystals, has been allayed by Government action that should ensure shipments from Jamaica. In view of some disposition to beatify logwood, it is instructive to notice how this dye was regarded in 1581, when a statute was passed to prevent its use. To quote the text: "There hathe byn brought from beyonde the Seas a certeyne kinde of Ware or Stuffe called Logwood alias Blockewood wherewith dyvers Dyers doe dye daylye . . . As the Colours made with the said Stuffe ys false and deceiptefull . . . all such Logwood shalbee forfeyted and openlye burnt." Logwood in those times was a scandalous substitute for woad and madder, gallnuts and sumac. In these days logwood provides presentable blacks and more doubtful blues, which the dyer improves by the sparing use of artificial dyestuffs. Madder, after being replaced by synthetic alizarin, is replaced further in some quarters by vegetable indigo, of the fastness of which there is no doubt. Woad, the most ancient of British dyestuffs, is still grown in Lincolnshire, and has been retained in limited use by a few wool dyers uninterruptedly.

The Carpet Business.—The war is understood to have postponed indefinitely a reorganisation of the carpet trade of this country. Carpet manufacturers, with few exceptions, belong to one or other of two trade associations already, and it is hardly a matter for doubt that important economies could be effected by bringing the whole industry under a unified control. It is apparent that too many types of carpet are made in given works to allow of the most economical production of each. Designs are more numerous than are indispensably needed, and, especially in printed carpets, the change of design has an important bearing upon the cost of work. The redistribution of work and the reorganising of the buying and selling departments offer promising scope for economy. If the war imposed no other obstacle the want of dyestuffs would be a sufficient bar to an immediate consummation of the large transaction contemplated. For want of colour, orders cannot

be executed on a scale to satisfy current demand, and the dearness of colour, taken with that of woollen, jute, linen and cotton yarns, keeps carpets at a high price.

Textile Journals.—In this country the technical side of textile journalism has three representatives, and all published in Manchester. The eldest of them, the *Textile Manufacturer* (monthly), had for its first editor the late Mr. Richard Marsden, an enthusiast in everything concerning textile work. Leaving that journal he founded the weekly paper the *Textile Mercury*, and made it the vigorous mouthpiece of employers in all that concerns their trade. The death of the second editor of that journal, Mr. Edward Ellis Marsden, eldest son of the founder, calls for respectful notice. Less of a public figure than his father, Mr. E. E. Marsden was held in the highest esteem. The *Textile Recorder*, founded by the late Mr. J. Nasmith and conducted by his son, is the third of the trio. In America textile journalism has flourished with an abundance certainly not to be matched here or upon the Continent. The *Textile World Record* of Boston, and the *Textile Manufacturers' Journal* of New York, the one monthly and the other weekly, have given respectively the best technical and best market news. They have united to form the weekly *Textile World Journal*, of which the first copies have reached this country. The *Wool and Cotton Reporter* and *Fibre and Fabric*, of Boston, are two other weekly industrial journals. The new monthly journal *Textiles* of Boston, appears in January, and is the venture of Mr. Samuel S. Dale, ex-editor of the *World Record*, an authority of pronounced and refreshing views upon trade politics.

NOTES ON BOOKS.

PRACTICAL ORGANIC AND BIO-CHEMISTRY. By R. H. A. Plimmer. London: Longmans, Green and Co. 12*s.* 6*d.* net.

Good arrangement and concise language, with avoidance of such vague superfluities as now so often serve to increase the bulk of technical books, are characteristics that are evident at a glance, and more detailed examination shows the author as a practical and orderly worker—moreover, a worker who can usefully enlist and guide others.

The author, who is Reader in Physiological Chemistry at University College, refers to the 150,000 carbon compounds that are now known, this remarkable multiplicity being due to the unique property which carbon possesses of being able to group itself or "combine with itself"; but as only a small number of these are concerned with vital processes, and this small number is more or less represented by types or representative substances, it becomes practicable to produce a comprehensive and thoroughly serviceable text-book within reasonable compass.

Laboratory practice, as far as it specially bears on the work of bio-chemistry, is treated of in forty-eight pages, this section giving detailed instructions as to important matters which may have been overlooked in the earlier chemical training of the student, as, for example, distillation, fractionation, and concentration *in vacuo;* the last process being of quite vital importance in relation to nearly all organic liquids that require concentration. We may refer to the somewhat complex apparatus for concentration *in vacuo* depicted on page 14: this is built up of quite usual laboratory appliances, and the sketch is supplemented by almost epigrammatically concise suggestions and instructions. Scarcely less important than evaporation *in vacuo* is the drying of crystals and solids at a controlled temperature under exhaustion, this matter being treated of in a remarkably practical way on pages 20 and 21. The device depicted is a glass vessel like a test-tube (set horizontally) for containing the substance to be dried; this is connected with a receptacle containing phosphoric anhydride, the "test-tube" being heated externally to the required temperature.

Mr. Plimmer's systematic study of bio-chemistry differs from many other systems by making the compound rather than the biological aspect or function the text, and thus he quite appropriately commences with a study of the essentials and the constitution of the hydrocarbons and of their reactions, hydrogenation in the presence of a nickel or platinum catalyst being duly emphasised. As bearing on hydrogenation, we may perhaps be allowed to refer to what may be an important aspect, detailed in the last-published (November 30th, I. p. 933) issue of the *Journal of the Chemical Society*, namely, hydrogenation by a catalyst suspended in an inert liquid, the hydro-carbon (ethylene) and the hydrogen bubbling through.

When our author comes to enzymes, proteins, and the haemoglobins, he perforce has somewhat to modify his plan of leading with the chemical compound rather than the bio-aspect or the function; but the extension of our knowledge in the future may allow of a full and strict application of the author's very desirable system in subsequent editions.

The haemoglobins are treated of with that fullness which the subject justifies, a frontispiece plate showing absorption spectra, and it is interesting to note the remarkably slight difference between the absorption spectrum of oxygenated blood (oxyhaemoglobin) and blood saturated with carbon-monoxide (carboxyhaemoglobin). Although nitric oxide haemoglobin is mentioned in the text the absorption spectrum is not given. It may be conjectured that the remarkable after-effects of inhaling nitrous fumes may be partly due to the inhibiting of the blood-function by the reduction of the higher or "red fume" oxides and formation

of the nitric oxide haemoglobin, this matter having a notable interest at the present time in relation to the war and the effects of the various asphyxiating vapours. On page 478 we find a suggestion that the red colour of meat pickled with potassium nitrate is due to the presence of nitric oxide haemoglobin.

The parallel subject of the chlorophylls is treated of with a commendable thoroughness and with a full appreciation of the most recent researches by Willstätter and his school.

Not many weeks ago we were glancing over Otto Funke's "Atlas of Physiological Chemistry," which was published in 1853 by the Cavendish Society, and our feeling was one of regret that so little use has been made of the store of wealth contained therein—a feeling of regret which is tempered by finding that Mr. Plimmer has drawn freely on this source, and with due acknowledgment.

The book under notice is one which may be studied with profit, not only by the beginner, but also by the most advanced worker, and we hope that the general appreciation will be such as to lead to edition after edition, so as to keep pace with that rapid progress which characterises this branch of chemistry.

THE ANALYSIS OF NON-FERROUS ALLOYS. By Fred Ibbotson and Leslie Aitchison. London: Longmans, Green and Co. 7*s*. 6*d*. net.

According to the preface, the aim of the authors has been to include in one volume such processes of analysis as they consider to be accurate and rapid. Considerable predominance is given to electrolytic methods, and many forms of electrode are mentioned, ranging from "just a loop of moderately stout platinum wire" to "just ordinary platinum crucibles soldered autogenously to a stout platinum wire"—this latter being a remarkable multiple form which we do not remember to have seen in use. Extended surface for the cathode is, we are told, best obtained by using platinum wire gauze, and of the nine forms of electrode that are illustrated three are of gauze.

The estimation of iron in alloys containing only a small proportion is included in the scheme of the work, but as regards non-ferrous alloys generally the range included by no means covers the whole of the industrial ground, leading prominence being given to copper alloys.

Possibly we may be regarded as hypercritical if we say that a rigidly punctilious chemist may object to some of the forms of expression, as, for example, "ammonium hydrate is then added" (p. 137), an expression that suggests the isolation and handling of this elusive and perhaps mythical compound. Similarly vague is the "few drops of ammonia" on the same page. In each case an aqueous solution of ammonia is doubtless intended.

In a future edition there may be an elimination of some of the less important matter to make room for the inclusion of a wider range of metals as used in the industrial non-ferrous alloys.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m. :—

JANUARY 19. — LAWRENCE CHUBB, "The Common Lands of London: the Story of their Preservation." LORD FARRER will preside.

JANUARY 26.—J. ARTHUR HUTTON, Chairman of the British Cotton Growing Association, "The Effect of the War on Cotton Growing in the British Empire."

FEBRUARY 2.—S. CHARLES PHILLIPS, M.S.C.I., "Paper Supplies as affected by the War."

FEBRUARY 9.—PROFESSOR J. A. FLEMING, M.A., D.Sc., F.R.S., "The Organisation of Scientific Research." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, will preside.

FEBRUARY 16.—THE HON. LADY PARSONS, "Women's Work during and after the War."

FEBRUARY 23.—MISS H. B. HANSON, M.D., B.S., D.P.H., "Serbia as seen by a Red Cross Worker."

INDIAN SECTION.

JANUARY 13. — COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., late Survey of India, "The Romance of Indian Surveys." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, will preside.

FEBRUARY 17.—C. A. KINCAID, C.V.O., Indian Civil Service (author of "Deccan Nursery Tales," "The Indian Heroes," "The Tale of a Tulsi Plant," etc.), "The Saints of Pandharpur." LIEUT.-COLONEL SIR DAVID W. K. BARR, K.C.S.I., will preside.

MARCH 16.—PROFESSOR WYNDHAM R. DUNSTAN, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India."

Dates to be hereafter announced :—

R. W. SETON-WATSON, D.Litt., "The Balkan Problem."

CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Optical Appliances in Warfare."

REV. P. H. DITCHFIELD, "The England of Shakespeare."

W. A. CRAIGIE, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

VICTOR HORTA, Directeur de l'Académie Royale des Beaux-Arts de la Ville de Bruxelles, "Belgian Architecture."

CHARLES DELCHEVALERIE, "Belgian Literature."

PROFESSOR T. G. MASARYK, "The Slavonic Peoples."

G. P. BAKER, "Hindu Hand-painted Calicoes of the Seventeenth and Eighteenth Centuries, and their Influence on the Tinctorial Arts of Europe."

SIR DANIEL MORRIS, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland."

JAMES MACKENNA, M.A., I.C.S. (Deputy Commissioner, Myaungmyn, Burma, and designated Agricultural Adviser to the Government of India), "Scientific Agriculture in India."

INDIAN SECTION.

Thursday afternoons at 4.30 p.m.:—

April 6, May 18.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

February 1, March 7, May 2.

CANTOR LECTURES.

Monday afternoons at 4.30 p.m.:—

J. ERSKINE-MURRAY, D.Sc., F.R.S.E., M.I.E.E., "Vibrations, Waves, and Resonance." Four Lectures.

May 1, 8, 15, 22.

FOTHERGILL LECTURES.

Monday afternoons, at 4.30 p.m.:—

REV. DR. HERBERT WEST, D.D., A.R.I.B.A. (author of "Gothic Architecture in England and France"), "Flemish Architecture." Three Lectures.

February 7, 14, 21.

EDWARD A. REEVES, F.R.A.S., Map Curator, Royal Geographical Society, "Surveying." Three Lectures.

March 27, April 3, 10.

JUVENILE LECTURES.

These Lectures will be given on Wednesday afternoons, January 5 and 12, at 3 p.m. The first lecture will be given by Professor John M. Thomson, LL.D., F.R.S., on "Crystallisation," and the second by Mr. James Swinburne, F.R.S., on "Science of some Toys."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 3...Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 3.30 p.m. (Juvenile Lecture.) Mr. R. Connor, "Canada and the New Empire."

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m. 1. Dr. R. Seligman and Mr. P. Williams, "The Action of Boiling Acetic and other Acids on Aluminium." 2. Mr. S. G. Sastry, "The Action of certain Chlorinated Hydrocarbons on some Metals in the presence of Moisture." 3. Messrs. C. Savill and A. W. Cox, "The Viscosity of Oils in the Redwood and Ostwald Viscometers." 4. Mr. R. C. Frederick, "The Estimation of Carbon Dioxide in Air by Haldane's Apparatus." 5. Mr. F. H. Newington, "A method for the determination of free Caustic Alkali in Soap." 6. Exhibition of Chemicals and Apparatus.

Geographical Society, Town Hall, Kensington, W., 3.30 p.m. (Juvenile Lecture.) Mr. H. C. Woods, "Constantinople."

TUESDAY, JANUARY 4...Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Professor H. H. Turner, "Wireless Messages from the Stars." (Lecture IV.)

Röntgen Society, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8.15 p.m. 1. Mr. J. H. Gardiner, "Some Observations upon the Occurrence of Uranium." 2. Exhibition of Specimens and Apparatus.

WEDNESDAY, JANUARY 5...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 3 p.m. (Juvenile Lecture.) Professor J. M. Thomson, "Crystallisation." (With experiments.)

Geological Society, Burlington House, W., 5.30 p.m. Mr. E. B. Bailey, "The Islay Anticline (Inner Hebrides)."

Child Study Association, University of London, South Kensington, S.W., 5.30 p.m. Dr. C. W. Saleeby, "Saving the Future."

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 3.30 p.m. Mr. W. H. Garrison, "The Wonders of the Antipodes."

Sanitary Engineers, Caxton Hall, Westminster, S.W., 7.30 p.m. Presidential Address.

THURSDAY, JANUARY 6... Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Professor H. H. Turner, "Wireless Messages from the Stars." (Lecture V.)

Optical Society, at the Chemical Society, Burlington House, W., 8 p.m. Mr. S. D. Chalmers, "The Use of a Graticule in Binoculars and Telescopes."

FRIDAY, JANUARY 7...Geographical Society, Town Hall, Kensington, W., 3.30 p.m. (Juvenile Lecture.) Mr. P. M. Roxby, "Pictures of China and Korea."

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 3.30 p.m. Miss G. Bacon, "Flying Machines in Peace and War."

Geologists' Association, University College, W.C., 8 p.m. Dr. C. W. Andrews, "The Discovery and Excavation of a large specimen of Elephas Antiquus."

SATURDAY, JANUARY 8...Royal Institution, Albemarle-street, W., 3 p.m. (Juvenile Lecture.) Professor H. H. Turner, "Wireless Messages from the Stars." (Lecture VI.)

Journal of the Royal Society of Arts.

No. 3,294. VOL. LXIV.

FRIDAY, JANUARY 7, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 12th, 3 p.m. (Juvenile Lecture.) JAMES SWINBURNE, F.R.S., "The Science of some Toys."

THURSDAY, JANUARY 13th, at 4.30 p.m. (Indian Section.) COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., late Survey of India, "The Romance of Indian Surveys." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

BOOKS OF TICKETS.

Fellows are reminded that they have the privilege of giving admissions to all the Society's meetings to two friends, and a book of the usual tickets for the purpose will be sent to any Fellow who will apply for it to the Secretary.

JUVENILE LECTURE ON "CRYSTALLISATION."

On Wednesday afternoon, January 5th, Professor John M. Thomson, LL.D., F.R.S., delivered the first Juvenile Lecture, the subject being "Crystallisation."

Professor Thomson commenced by describing the various conditions under which material substances are found in Nature—gaseous, liquid, plastic, and solid — pointing out the gradual passage of one condition into the other; this passage depending greatly on changes of temperature. He stated that for the purposes of the lecture that afternoon his remarks would relate to the solid condition of matter, and more particularly to certain properties in those substances which assume definite crystalline form.

Some general properties belonging to crystals were then described, and experiments shown illustrating the different effects exercised by them on a beam of light, either plain or polarised. Slides were exhibited on the screen showing the effects of double refraction, and the colours produced by various crystalline substances when viewed by polarised light.

Professor Thomson next spoke of the various ways in which crystals may be produced; illustrating these experimentally in the formation of crystals by sublimation, and their deposition from states of fusion and solution. He pointed out the necessity for the component parts of the crystallising substance having great freedom to move, so as to assume the crystalline shape, and therefore that deposition from a state of solution may be regarded as the most convenient and common method for obtaining crystals. After describing what is meant by hot and cold saturated solutions in connection with the solution of salts, the lecturer exhibited crystals depositing from their solutions in different forms. Models and diagrams of the various forms of crystals were shown. The difference between hydrated and anhydrous salts was explained. The relation of water to the composition and sometimes to the colour of the salt when combined with it was illustrated by the distillation of blue vitriol ($CuSO_4 . 5H_2O$); when the colour of the blue crystals disappeared and clear water was distilled from the salt, the forms of the crystals also disappearing during the distillation. The reunion of water with the dried mass was shown, when the blue colour was, to a certain extent, restored, but the crystalline shape could not be reformed till the salt had been redissolved in water and allowed freedom to crystallise. The physical circumstances accompanying the union of water (*a*) with an anhydrous salt, and (*b*) with an already hydrated salt, were explained; the heat evolved in the first case being experimentally

contrasted with the cold produced in the second. Methods other than by heating for the removal of water from salts were shown, such as the addition of a third substance to the solution of a salt, which uniting with the water originally combined with the salt abstracts it, causing the deposition of the salt in an anhydrous condition. Further experiments were shown on the relation of colour to the composition of crystalline bodies by means of the various colour changes seen in the salts of the metals cobalt and nickel, changes originally used in sympathetic inks. That change in colour might take place without apparent change in composition was proved by heating the red crystalline variety of mercury iodide, which at once changed to a yellow variety. On allowing this to cool and rubbing with a hard substance, the crystals at once revert to the red variety. When the particles of the crystalline salt are widely separated from each other by solution the colour may disappear, and the solution become colourless. On the separation, however, of the salt in the crystalline condition on cooling, the original colour reappears. This was shown in the crystallisation of yellow lead iodide from a clear hot solution of that substance in water.

The lecturer then described certain cases in which the solution of the crystalline salt in water, and its deposition therefrom, departed somewhat from the normal conditions of crystallisation. He drew attention in these exceptions specially to the cases of common salt, which is almost as soluble in cold as in hot water; to calcium sulphate, which is less soluble in hot than in cold water; and to Glauber's salts, which increases in solubility up to a temperature of 33° C., and then decreases. At that temperature the salt $Na_2SO_4 . 10H_2O$ is said to have its point of maximum solubility. He showed that if a solution of this salt be prepared at that temperature, and when hot tightly stoppered, the solution would on cooling remain liquid without the deposition of any crystals. On opening the flask however, when cold, and allowing the air to enter, crystallisation at once begins, and the whole mass ultimately is deposited in the crystalline form. This constitutes the phenomenon of so-called supersaturation. It was then shown that it was not necessary to have the flask closed by a cork, but that if stoppered instead with a plug of cotton-wool, which filtered the air as it entered the flask whilst cooling, the same result could be obtained. The cause of this sudden solidification in such solutions has attracted much attention. That it is not due to shaking could be shown by blowing air from the lungs through the solution, when no crystallisation took place; but on blowing unfiltered air from a pair of bellows, crystallisation very soon occurs. Evidently some nucleus is required, and Professor Thomson proceeded to show experimentally the nature of the nucleus which proved active in starting this crystallisation. Substances cut into the same crystalline shape as that of the salt in solution, or even crystals themselves, if they are of a different crystalline form from the salt in solution, are *inactive* to the solution; but a crystal of the substance itself which is in solution is invariably *active* in promoting solidification. Other salts, provided they are truly isomorphous with the salt in solution—that is, having the same crystalline form and a similar chemical structure—are also *active* in causing crystallisation. As illustrating this point, interesting experiments were shown in which layers of supersaturated solutions of different salts, one above the other in long tubes, were crystallised by nuclei consisting of crystals of the salts present in each different layer. Crystalline salts may thus be separated from mixed solutions of dimorphous salts by the action induced by their respective nuclei. Professor Thomson concluded by showing certain physical phenomena connected with the solidification of these solutions; more particularly the great evolution of heat which takes place in the passage of the liquid to the solid condition, this being contrasted with the experiment shown at an earlier part of the lecture, demonstrating the production of cold by the conversion of a solid salt into a state of solution.

On the motion of the Chairman a hearty vote of thanks was accorded to Professor Thomson for his interesting lecture, and the meeting terminated.

THE WORLD'S SUPPLIES OF FUEL AND MOTIVE POWER.*

Industrial Civilisation requires Coal, Oil, and Motive Power.†—The present civilisation of the

* Extracted from the Thomas Hawksley Lecture, delivered before the Institution of Mechanical Engineers by Dugald Clerk, D.Sc., F.R.S., on October 29th, 1915.

† Just before delivering this lecture, my attention was called to an able work entitled "Natural Sources of Energy," by Professor A. H. Gibson, D.Sc., of University College, Dundee. This interesting work was published in 1913, and in it is discussed the problem of the fuel and motive power of the world in a careful and comprehensive manner. The results given here agree generally with Professor Gibson's conclusions, although arrived at independently from somewhat different data.

world rests upon a basis of coal and oil fuel, and water, steam, and internal-combustion motive power. At the middle of the eighteenth century the United Kingdom had but the small population of ten and a half millions. It was only entering into the stage of transformation from a purely agricultural country to the first great industrial community of the world. Previous to that time motive power had only been available to a small extent, as provided by water and wind. True, the Newcomen steam-engine then existed, but its use was strictly limited. In the third quarter of that century the work of James Watt raised steam-power from a wasteful process to a relatively economical one; and in the first instance the early Watt engines were entirely used for pumping out mines. The development of the steam-engine by Boulton and Watt was thus continued, and necessitated by the needs of the hydraulic engineer.

The coal consumption of Newcomen's engine was about 20 lb. per i.h.p., while that of Boulton and Watt was from 5 to 7 lb., about one-fourth to one-third of the pioneer engine.

Engineers' later efforts greatly improved upon these figures; thus triple-expansion engines require 2 lb., large steam-turbines 1½ lb., and suction gas-engines 1 lb. per i.h.p.

The success of the Watt steam-engine enabled coal-mining to be firmly established and coal output increased; and this increase of output was accompanied by the rapid invention and application of numerous mechanisms and processes leading to the plentiful production of iron, steel, textile fabrics, chemical manufactures—soap, alkali—the whole mechanism, in fact, required for the existence and comfortable subsistence of the rapidly increasing population of these islands, which in 1801 had risen to over fifteen and a half millions.

The steam-engine was rapidly applied to stationary purposes, driving mills and works of various kinds, then to marine engines, and last of all to land locomotives, and by the middle of the nineteenth century in its reciprocating form it had firmly established itself as the greatest source of motive power for man's use. The low cost of coal and the large amount of power obtained from steam for small capital and running expenditures at first made it unnecessary to think of economising too closely. As time went on, however, the amount of power required rapidly increased. For example, at the beginning of the nineteenth century the steam-power developed in stationary engines in the whole kingdom did not amount to more than 4,000 h.p., and even in 1836 an engine developing 40 h.p. was considered a very important undertaking. In 1836 this power had risen to about 30,000 h.p.

The Committee of Managers of the Birmingham Philosophical Institution published a report on October 3rd, 1836, which gave, among other things, a statement of the steam-power employed in Birmingham in 1835; it amounted in all to 2,700 h.p. divided among ten industries, and employed 4,000 men and 1,300 women.

Total Power of Industrial Engines in Great Britain in 1907.—In the first census of production for the year 1907, the total power of industrial engines in use in Great Britain and Ireland is given as 10,578,475 h.p., and the steam-engine power of road rollers and road locomotives owned by public authorities amounted to 167,192 h.p. Of the industrial engines, steam reciprocating engines were rated at 9,118,818 h.p.; steam turbines, 530,892; internal-combustion engines, gas, oil, etc., 680,177; and water power, 177,907 h.p. The persons employed in the factories using this large power numbered nearly 10½ millions; so that, roughly, the power available for the industries of Britain was nearly 1 h.p. per person employed. To support the 46 millions of people now living in the United Kingdom thus requires a continuous enormous expenditure of power, and a very large consumption of fuel.

The total coal known to be in existence in the world is given by Mr. D. B. Dowling as 7,397,553 million tons, and the total output of the whole coal of the world in 1913 was 1,363,878,110 tons. Assuming that rate of consumption to continue, obviously we have over 5,400 years' supply.

The Report of the Royal Commission on Coal Supplies, issued in 1905, as the result of an elaborate investigation, gives the contents of the proved coal-fields of the United Kingdom as 100,000 million tons, and estimates coal in still unproved fields as 40,000 million tons. If one can assume them to realise 25,000 million tons, then at the present yearly consumption of 250 million tons we have still 500 years' supply.

In the year 1903 the output of coal from Britain was, in round numbers, 230 million tons. Of this, about 168 million tons were consumed in the country and 62 million tons exported. Much of this exported coal, however, was used for coaling purposes for British steamers abroad. Under these circumstances it becomes highly important to the country at large, and very interesting to the engineer, to consider what can be done, first, to reduce the rate of use of our coal to a minimum, and second, to study how motive power is to be procured and industry carried on in a coal-less Britain.

In evidence given before the Royal Commission, Dr. G. T. Beilby, F.R.S., makes the interesting calculation that out of an annual consumption of from 143 to 168 million tons of coal, there is a possible saving of from 40 to 60 million tons. I have taken Dr. Beilby's figures for the higher consumptions mentioned, and calculated from his division the percentage used for each separate purpose in the table on page 140.

Dr. Beilby's estimated saving is thus 60 out of 168 million tons annually, 35·7 per cent. of the portion used for home consumption, or 26·1 per cent. of the total, including the exported coal, and it increases the coal life of our country to

676 years. Dr. Beilby pointed out in a note published eight years later by the British Science Guild, that the large gas-engine had not developed so rapidly, and the steam-turbine had advanced more rapidly than expected, so that the savings he anticipated had not yet been circumstances we should be forced to dispense with it. But even if we allow 12 million tons of the 36 to be still used for radiation, the total coal bill would be reduced to one-half, and the industrial life of the country increased to 1,000 years. From this it appears that our present

——	Consumption in Millions of Tons.	Percentage.	Possible Saving.	How Saved.
Railways	14	8·4	7	Electric traction.
Steamers	8	4·7	—	——
Factories	45	26·8	30	Gas generators and engines.
Mines	12	7·2	7	Gas-engines and recovery ovens.

Domestic purposes	36	21·4	8	Gas cooking, heating, briquettes and coke.
	168	100·0	60	

realised. Even without the superior thermal efficiency of the internal-combustion engine, large steam-turbines generating power at central stations are capable of reducing the 45 million tons of coal required for power in factories to nearly Dr. Beilby's figure.

Under pressure of necessity, however, it will prove possible to make other economies, which, however, involve greater changes. Thus, exhaust heat from steam- and gas-engines is utilised at present to a certain extent in heating buildings and carrying on various manufacturing processes, but no comprehensive attempt has been made to supply motive power, light and heat from the combustion of the same fuel. Large central stations with gas-generators and high efficiency gas-engines would give all the motive power required for factories on 15 million instead of 45 million tons of coal, as shown in the table; but even then the waste heat from water-jacket, exhaust gases, and gas-producers equals that produced by burning 10 million tons. This distributed through a city as steam at 30 lb. or so pressure above atmosphere could readily supply heat for the household to warm the rooms and perform cooking operations. The high efficiency of steam-heating and cooking would enable the heat of 10 million tons to do the domestic work at present performed by 36 millions. The open fire would be missed, with its pleasing radiation, but under pressure of fuel-needs might be met by the use of half our coal consumption. Further economy may be effected by the extended adoption of water-power.

In order to reason with any approach to accuracy, it is necessary to arrive at some probable estimate of the total power available in the world, and to extend the inquiry not only to a coal-less England, but to a coal-less and oil-less world. The total energy available to us is due to solar radiation, past and present, tidal energy, and the earth's internal heat. The great source of all our energy is, of course, solar radiation. Taking Sir J. J. Thomson's estimate of 7,000 h.p.* per acre as the total radiation of the sun absorbed on the earth's surface with a clear sky, this is sufficient to produce 4,480 h.p. per square mile, assuming an absolute efficiency of conversion of one-tenth per cent. Such a result, however, can only be hoped for in desert districts, where the sun's rays are not obstructed by clouds or vapour. If this enormous energy were easily available, then engineering problems would chiefly deal with the generation of motive power in great deserts such as those existing in Africa, and the transmission of the power so generated to districts where man could live and pursue his manufactures.

* Professor A. H. Gibson gives the value as 8,000 ft.-lb. per minute per square foot in areas between the Equator and 45° North and South latitudes.

Sun Power.—Though many engineers, including Ericsson, have experimented with sun engines,* so far no method of using the direct solar energy of radiation has been invented which is capable of supplying any large amount of power. The world, however, may be considered as a huge solar engine, in which the waters of the seas are evaporated by the heat absorbed, and much of the vapour carried to high levels, at which it is deposited as water, and flows down to the sea. By this process we get a complete cycle of operations, including evaporation of water into steam, condensation of the steam into water, evaporation again, and so on. In falling from the high level to the low level of the sea, power can be obtained from this water. Hydraulic power, in fact, is a form of sun power, and will continue in existence long after all the coal and oil in the world have been exhausted. Coal and oil have also been produced by the action of the great solar engine, and they contain a proportion of the energy of radiation of past ages, stored up in the growing wood and leaves of plants; accumulations which are now being rapidly drawn upon by mankind. Coal and oil are thus the result of past radiant energy, while wind and water-power are due to present radiant energy. In one case the store in the earth is being used up and cannot be replaced; in the other case, so long as the solar system lasts, power exists also. Mr. Ellington very clearly took this view in the first Hawksley Lecture, when he said: "On a review of the whole subject, it appears that water-power is likely to become increasingly important. It is perennial in its source. As a mechanical agent it has numerous ramifications, which are constantly extending, and its direct application to industry offers a large field for the exercise of the talents of the inventor and the engineer."

Increasing Importance of Hydraulic Power.—Although I have devoted myself to the rival power obtained by internal combustion, I thoroughly agree with what Mr. Ellington has said. Undoubtedly as time goes on, hydraulic power must become of increasing importance. Mr. Ellington estimated the average rainfall in the United Kingdom as 25 in. per annum, and he calculated that, assuming a fall of 500 ft., this gave 100 h.p. per square mile continuing throughout the year. But a small part of the area of the United Kingdom is at so high a level as 500 ft. The total area of the United Kingdom is roughly 121,000 square miles. Taking suitable ground of 500 ft. level at 5 per cent. of the total area, and assuming it possible to construct artificial lakes by means of dams, from this area nearly two million h.p. could be obtained, available for eight hours per day every day of the year. In some areas of England the rainfall is more than 60 in. per annum, and on these areas the altitude is about 1,000 ft.

* Professor Gibson gives an account of recent solar motor experiments.

Mr. Alexander Newlands, Chief Engineer of the Highland Railway, read a most interesting Paper before the British Association in 1912, on Scottish Water-Power, in which he adopts the view of Professor G. Forbes, F.R.S., that the available hydraulic power in Scotland exceeds one million h.p. Mr. Newlands has investigated many convenient power stations, and gives a list of forty-five localities, from which he considers a total of 205,000 h.p. could be obtained. He states that the Kinlochleven Works of the British Aluminium Co., on the west of Argyllshire, cost £600,000, and develop 30,000 h.p., at a capital expenditure of £20 per h.p. The total cost of current used is one-sixteenth of a penny per unit, after allowing for interest on capital and depreciation.

The average investment cost of all American water-powers he gives as £40 per h.p. developed. Mr. Newlands comes to the conclusion that installations costing up to £20 per h.p. could deliver power at a cost with which no steam plant could hope to compete. In Norway and Sweden, where Pelton wheels are used, with high heads, installations exist which cost £10 per h.p., and in these countries power has been advertised for sale as low as thirty shillings per h.p. per annum. Mr. Newlands quotes the *Electrical Review's* comparison of the minimum costs of an electrical horse-power per annum from

	£	s.	d.
Water in Switzerland	1	19	0
Steam in England	4	11	8
Blast-furnace gas in Germany .	4	1	7
Producer-gas in England . . .	5	0	0

From these figures, it is evident that in Scotland, even at the present time, hydraulic power presents economic advantages when compared with power obtained from the cheap coal of to-day by steam- and gas-engines. With increasing scarcity of coal, undoubtedly hydraulic power will in the future show greater advantages, and even in England and Ireland it might be possible to earn interest on capital expenditure greater than £40 per h.p. By great engineering works, it might be just possible to obtain perhaps three million h.p. from areas which could be given up for the purpose. This power obviously is insufficient for British needs.

To increase production, other sources may be drawn upon. In the conditions assumed, the only other source of energy at all comparable to water is the yearly fuel growth of trees and undergrowth. It is difficult to arrive at any probable value of wood growth in the United Kingdom. The whole area under forests is 3,081,754 acres, and I can find no published figures dealing with annual yield. The total area of German forests is given as 34,569,800 acres, and the yearly yield as 26,183,410 cubic yards of timber, and 23,348,640 cubic yards of

firewood. Taking a cubic yard of firewood as weighing 0·6 ton gives 14 million tons as the annual growth of firewood in Germany. This equals 6,200,000 tons of coal in heating value. The forest area of the United Kingdom is about one-eleventh of that of Germany, so that on this scale we could only produce heat equal to 563,000 tons of coal. Obviously firewood growth with us cannot be expected to give more than about 350,000 h.p. No doubt larger areas will be devoted to forests in the future, and greater power obtained, but I fear even then the yield could not make up for the loss of coal. There only remains wind and tidal power for consideration. Wind power may be neglected. Tidal power, however, would add materially to the total, but at the cost of great, inconvenient, and expensive works.

Oil does not materially affect our problem. The total oil produced from wells and distilled from shale in the world is about 5 per cent. of the weight of coal raised, and according to Sir Boverton Redwood, even if the whole of the crude petroleum were employed as fuel, in steam raising, it would not replace, allowing for its high thermal value, much more than 5 per cent. of the world's output of coal; while if used in internal-combustion engines, it would be equivalent as a source of power to about 15 per cent. of coal. Only a small proportion, however, of the crude petroleum can be regarded as available for use as a source of power, for by far the larger part is in demand as an illuminating agent, and as a lubricant for machinery.

Sir Boverton Redwood states also: "Some of the older oil-fields of the United States are becoming exhausted, and Dr. David T. Day, of the United States Geological Survey, considers that at the present rate of increase of the output of petroleum, the known oil-fields of that country will, on the basis of the minimum quantity of oil obtainable, be exhausted by the year 1935, whilst even if the present output were only maintained, the supply would, on the same basis, not last for more than 90 years." The oil supply of the world, accordingly, does not greatly help us to extend the duration of industrial civilisation. The earth's heat—the only other source of power—is unavailable, and could not be drawn upon in our present state of knowledge. In the absence of coal, then, it appears that all the energy available for power in the United Kingdom would not exceed 4 million h.p., or 6·5 million h.p. less than is at present used in our factories alone.

But we also require fuel to produce power for railways and ships. In the table (page 140) railways use 8·4 per cent. and factories 26·8 per cent. of our total coal consumption. Assume that locomotives require the same weights of coal as factories for each horse-power developed, then the locomotive power of our country is about 3·3 million h.p. Our mercantile marine requires another 5 million h.p., and the Royal Navy in time of war also requires 5 million.

Altogether, to carry on the industrial civilisation of these islands in time of peace, on the scale of to-day, absorbs a power of about 19 million h.p., and without coal we could only obtain 4 million. Obviously, a change of condition such as this necessarily involves great modifications in our social life and a large reduction in the population which we can support in comfort.

Taking 1,100 million tons as the world's output of coal for 1907, on the assumption that the proportion used for factories and railways is the same as in our country, then the world's factories require 295 million tons, and railways 93 million tons. Assuming the same consumption per h.p., the world's factories require 60 million h.p., and the world's railways 19 million. I have estimated the power of the world's shipping as—mercantile marine, 10 million h.p.; warships, 13 million h.p. The total power used in the world generated by the combustion of coal is thus of the order of 100 million h.p.:—*

	Million h.p.
World's factories	60
World's railways	19
World's ships	23
	102

This estimate does not include existing hydraulic power. Assume it to be 13 million h.p. Then the total power required in a coal-less world would be 115 million h.p. There is little doubt that the hydraulic supply of the world† is capable of producing more than this, so that even when our world's coal is exhausted all the power required will be forthcoming. In this case, however, storage batteries must be greatly improved to enable ships to be propelled electrically. But as about 40 per cent. of the world's coal is consumed in producing motive power, 60 per cent. of the heat value of the total coal must be replaced from some other source. The only further source of heat would then be growing wood; a large quantity would be grown in tropical countries and transported as charcoal, but fuel so obtained would be expensive, and heat and chemical action in domestic and metallurgic use would be economised to the utmost.

It is very evident, therefore, from this short discussion, that the line of the engineer's duty is to be found in economising all the energy remaining in these islands in the form of coal, and thus postponing the period of industrial change in England. Engineers have long felt the pressure of this duty, and have strenuously

* Professor Gibson gives the same figure, 100 million h.p., but arrives at it in a different way.

† Professor Gibson's estimates of the total available water-power of the world is 200 million h.p.; United States of America water-power from 35 to 55 million h.p., of which 5·3 million were utilised in 1908.

endeavoured to find means of obtaining power at less and less fuel cost; so that even while Watt and Boulton were still struggling to make the condensing steam-engine a commercial success, others were experimenting with various schemes which did not require the use of steam. In these days it was felt that part of the loss of energy experienced in obtaining motive power by steam was due to the latent heat of the steam in passing from the liquid to the gaseous state. This was true in a limited sense, but the science of thermodynamics had no existence until about 1840, and accordingly engineers had nothing to guide them in determining the laws by which heat produces mechanical work. The idea, however, that latent heat absorbed heat energy undoubtedly had its effect in provoking attempts to use atmospheric air as a source of motive power.

Stirling and Ericsson's Hot-Air Engines.—The earliest hot-air engine which was reasonably successful was the invention of a clergyman, Dr. Stirling. In this engine air was heated at constant volume with increase in pressure, and the power was obtained by subsequent expansion. In another engine of what is now known as the constant-pressure type, Ericsson, the well-known American engineer, compressed air, heated it at constant-pressure, and expanded it in a larger cylinder than the compression cylinder. In both the Stirling and the Ericsson engines a contrivance known as the regenerator was used, which was the subject of much controversy and misunderstanding. The early Stirling engine was produced in 1815, but thirty years after a paper was read by Mr. James Stirling at the Institution of Civil Engineers upon "Stirling's Improved Air Engine." The main improvement consisted in working with air at a greater original density than that of the atmosphere, and the engine had so far succeeded that two had been used at the Dundee Foundry Co.'s works, one giving 21 h.p. and the other 45 h.p. Mr. Stirling claimed that the 21-h.p. engine required only 2½ lb. of coal per h.p. hour. This is an extraordinarily good result, and could only have been obtained by the action of the regenerator. It is clear, however, from the paper and from the discussion, that many engineers then imagined that, with a perfect regenerator, no heat would disappear in performing work. The speakers in this discussion included Robert Stephenson, and, curiously enough, he plainly misunderstood the whole process of action of Stirling's engine. His remark on the regenerator was illuminating: "He understood the process to consist of heating the air in a vessel, whence it ascended to the cylinder between numerous thin laminæ, by which the caloric was absorbed, to be again given out to the descending air. Now, it appeared to him that, though the ascending process was natural and easy, the reverse action would require a certain expenditure of power, in the depression of the plunger." A Mr. Cottom said: "It was evident that if it was practicable to arrive at the theoretical condition of the absorption of all the caloric by the thin laminæ during the upward passage of the air and the giving it out again during the downward passage, there would not be any loss of heat."

Other papers were read on the same subject at the Institution of Civil Engineers in 1853, and the discussion interests us particularly, because Mr. Thomas Hawksley joined in it. Mr. Hawksley considered that the machine involved a mechanical fallacy, and that the regenerator produced no mechanical effect whatever. Here Hawksley was clearly in error, but he erred in good company, because at the same time the famous Dr. Faraday said: "Twenty years ago he had directed his attention to this question, and from theoretical views he had been induced to hope for the successful employment of heated air as a motive power; but even then he saw enough to discourage his sanguine expectation, and he had, with some diffidence, ventured to express his conviction of the almost unconquerable practical difficulties surrounding the case, and of the fallacy of the presumed advantages of the regenerator." Brunel also considered the use of the regenerator to be an entire fallacy. Sir George Cayley, about the same time, described another hot-air engine, which may be considered as the first of the internal-combustion type acting with solid fuel under constant pressure. In his engine he pumped air into a furnace, and led the heated products of combustion through valves into the interior of a cylinder. He also was unsuccessful. The Stirling and Ericsson engine worked, but both engines were extremely bulky and heavy. Ericsson built a hot-air engine for operating the hot-air ship "Ericsson" in America, and the cylinders were no less than 14 ft. in diameter. From these he got only about 300 h.p. Both types of engine failed, because of the rapid burning out of the cylinder bottoms with the direct action of the fire, as it was found impossible to heat the air rapidly enough to the required temperature without maintaining the temperature of the metal surfaces much higher than the maximum temperature to be attained by the air. Some inventors, as has been stated, proposed to heat the air by combustion, and Cayley's was the first attempt to do this with solid fuel. Cayley, however, introduced difficulties as grave as external heating, hot gases had to pass through pipes and valves to the motor cylinder, and this made it impossible to maintain a high temperature without damage to the machine.

Inventors dealing with internal combustion introduced into a cool cylinder a mixture of gas or inflammable vapour and air at atmospheric pressure, ignited this mixture at constant volume, and drove a piston by the increase

in pressure. Professor Farish, of Cambridge, at his philosophical lectures at the University, exhibited a model engine so operated as early as 1817. Other inventors attempted to operate their engines by atmospheric pressure, producing the necessary vacuum or reduction of pressure by the combustion of an inflammable gas in air.

The Cecil Engine.—The Rev. W. Cecil, M.A., of Cambridge, read a paper in the year 1820 before the Cambridge Philosophical Society, on the application of hydrogen gas to produce a moving power in machinery, with a description of an engine which is moved by the pressure of the atmosphere upon a vacuum caused by explosions of hydrogen gas and atmospheric air. He described an engine which he had constructed to operate on the explosion vacuum method. He thus explains the principle of his engine: "The general principle of this engine is founded upon the property which hydrogen gas mixed with atmospheric air possesses of exploding upon ignition so as to produce a large imperfect vacuum. If two and a half measures by bulk of atmospheric air be mixed with one measure of hydrogen and a flame be applied, the mixed gas will expand into a space rather greater than three times its original bulk. The products of explosion are, a globule of water formed by the union of the hydrogen and the oxygen and the atmospheric air and a quantity of azote, which, in its natural state (or density, 1) constituted 0·556 of the bulk of the mixed gas. The same quantity of azote is now expanded into a space somewhat greater than three times the original bulk of the mixed gas—that is, into about six times the space which it occupied before; its density is therefore about one-sixth, that of the atmosphere being unity. If the external air be prevented by a proper apparatus from returning into this imperfect vacuum, the pressure of the atmosphere may be employed as a moving force nearly in the same manner as in the common steam-engine; the difference consists chiefly in the manner of forming the vacuum."

The operation of the engine consisted in drawing into the cylinder a proportion of atmospheric air and hydrogen, igniting this mixture at the end of the stroke, allowing the hot gases to be discharged from the cylinder by the pressure of combustion, then cooling the gases in the cylinder and producing a vacuum to operate the piston.

Mr. Cecil stated that the engine rotated at 60 revolutions per minute: in practice it was found to work at considerable power and perfect regularity. In the model constructed, the engine used 17·6 cubic feet of hydrogen gas per hour. Evidently, however, the engine was rather noisy, because the inventor stated: "To remedy the noise which was occasioned by the explosion, the lower end of the cylinder A, B, C, D, may be buried in a well, or it may be enclosed in a large air-tight vessel." This engine is very crude, but extremely ingenious. It is also interesting to note that Cecil made experiments by which he determined approximately the maximum pressure produced by means of a mixture of hydrogen and atmospheric air. He gives this maximum pressure as 180 lb. per square inch absolute.

The Brown Engine.—Mr. Cecil did not carry his invention further, but another inventor, Mr. Samuel Brown, took out patents in 1823 and 1826 in which he operated by filling a vessel with flame to expel its contained air and throwing in a jet of water to condense the flame. This produced a partial vacuum, and the atmospheric pressure was made available for utilising the power by means of an ordinary piston. Samuel Brown was very persevering, and according to the *Mechanics' Magazine* published in London in August, 1824, he had then made a model which raised 300 gallons of water 15 ft. high on one cubic foot of gas. In 1832 it appears that four of his engines were in use for pumping:—(1) One at Croydon at the canal, raising water from a lower to a higher level; (2) one at Soham in Cambridgeshire, for draining part of the middle fen district; (3) one at Eagle Lodge, Old Brompton; and (4) one at Eagle Lodge, Old Brompton, of the beam type. It was stated that the cylinder of the Croydon engine was 3 ft. 6 in. in diameter by 22 ft. high. Engine No. 3 was inspected by the editor of the *Mechanics' Magazine.* Its cylinder was 3 ft. 8¾ in. diameter by 22 ft. high; and it discharged 750 gallons per stroke, four strokes per minute, 12 ft. high. Brown claimed in a circular published in 1832 that the coke and tar obtained in making coal gas for the Croydon engine were sold for such sums as produced a profit in addition to giving motive power for nothing. He stated that the whole annual expense of the Croydon gas vacuum engine, including coal, wages, repairs, depreciation, rent, amounted to £666 14*s.* 0*d.*, while the receipts from the sale of coke and tar were £769 12*s.* 0*d.*, so that the annual profit was £102 18*s.* 0*d.*, without counting the value of the pumping work done, which previously cost the Canal Co. £275 per annum to effect by steam-engine. This state of affairs, however, could not have been permanent, as after some years of work the engines were displaced. Brown also applied his vacuum gas-engine to driving a carriage in 1825 and to propelling a boat on the Thames in 1827. These early attempts were obviously inspired by the low-pressure steam-engine with its vacuum obtained by steam, but no real success was attained, the gas consumption—that is, the consumption of heat for producing a given power—being very high.

Lenoir Gas-Engine.—Meanwhile the work of Joule, determining the mechanical equivalent of

heat, taken together with that of Macquorn Rankine, Thomson and Clausius, based partly on the earlier investigations of Carnot, had developed a definite theory of the relationship between heat and mechanical work. Accordingly, we find the advocates of internal combustion increasingly active, and in 1860 Messrs. Marinoni introduced in Paris the famous Lenoir gas-engine. In it the principle is exceedingly simple and evident. The piston moved forward a part of its stroke by the energy stored in the fly-wheel, and took into the cylinder a charge of gas and air at the ordinary atmospheric pressure. The valves cut off communication, and the explosion was occasioned by electric spark. The piston was thus propelled to the end of the stroke. Exhausting was performed exactly as in the steam-engine. This engine was practicable but very uneconomical. It was largely used, however, for pumping. One such engine was inspected by the author at Petworth House, Petworth, in 1882, and it had then been working, pumping water, for about twenty years. This engine was replaced some years ago by an engine of the National Gas Engine Co.'s manufacture, which was used both for pumping and electric lighting.

The Engines of Otto and Clerk.—It was very soon found that, to obtain economy in an internal-combustion engine, compression was necessary, and the history of the modern internal-combustion engine dates from Beau de Rochas' famous pamphlet in 1860, in which the alternate use of a cylinder as pump and motor and the use of considerable compression was fully described. To the late Dr. Otto, however, belongs the honour of bringing this type of engine into practical use. This he did in 1876. Otto's was the first compression gas-engine to succeed in practice. I produced my first compression engine in 1878, and exhibited it at work at the Kilburn Royal Agricultural Show in 1879. In this engine compression was also used, but an impulse was obtained at every forward stroke of the motor piston. The engine best known, however, as of the Clerk type was not produced till 1881, in which year it was exhibited at an Electrical Exhibition in London and later in Paris. This engine was the first in which the piston overran ports by which the exhaust was discharged, and where the charge was admitted to the cylinder from a separate pump in such a way as to discharge the exhaust products before it. Practically all the internal-combustion engines of the world now operate either on the Otto four-stroke or on the Clerk two-stroke system. In these engines the explosion takes place at constant volume, so that the pressure rises.

Constant-Pressure Engine.—As far back as 1873 a constant-pressure engine was introduced by an American inventor, Brayton. This engine resembled a hot-air engine in which air was compressed into a reservoir at a constant pressure, then expanded into a working cylinder at the same pressure, and the volume increased by the formation of flame. Brayton's engine used light petroleum, and it had a certain success. It had considerable application for stationary work, and it was intended to apply also to the propulsion of boats and vehicles. The modern constant-pressure engine, however, does not work in the Brayton manner. The Diesel type depends upon the compression of air to about one-twelfth of its original bulk in a cylinder, the raising of the temperature of the air to a sufficient extent to ignite heavy oil when injected into it in fine spray. The injection occurs from the beginning of the stroke during a very small advance of the piston on its forward stroke. A diagram is thus produced which is substantially a constant-pressure diagram. This engine is extensively used for many purposes, including pumping. It sometimes operates on the Otto and sometimes on the Clerk cycle. The smaller engines use the Otto method and the larger the Clerk method.

Comparison of Steam and Internal-Combustion Engines.—During many years, compression was continuously increased in constant-volume types of engine, and with increased compression came increased economy of fuel. At the same time coal-gas was supplemented by other gaseous fuels; first, Dowson pressure-gas made from anthracite, then suction-gas from anthracite, coke and other fuels, and later waste gases from the blast-furnace. Many substances also were utilised to produce gas for engines, many of them waste products, sawdust, dried peat and wood chips of different kinds. Bituminous fuel was also used, at first only in conjunction with ammonia-recovery processes; later, on a smaller scale, for gas only.

Many obstacles were found to increasing engine dimensions indefinitely. In the early days of the internal-combustion engine, enthusiastic pioneers like myself considered that ultimately the internal-combustion engine would entirely displace steam. In a paper read at the Institution of Civil Engineers in 1882, I stated: "The gas-engine is as yet in its infancy, and many long years of work are necessary before it can rank with the steam-engine in capacity for all manner of uses; but it can quite well be made as manageable as the steam-engine in by no means a remote future. The time will come when factories, railways, and ships will be driven by gas-engines as efficient as any steam-engine, and much more safe and economical of fuel. Gas-generators will replace steam-boilers, and power will not be stored up in enormous reservoirs but generated by coal direct as required by the engine.

"The steam-engine converts so small an amount of the heat used by it into work that, although it was the glory and honour of the

first half of the century, it should be a standing reproach to engineers and scientists at the present time having constantly before them the researches of Mayer and Joule."

Other engineers like Sir Frederick Bramwell shared in this feeling. Sir Frederick even went so far as to predict that, by 1931, steam-engines would only be found in museums. A gallant attempt was made by those interested in the gas-engine to fulfil Sir Frederick's prophecy, and very great progress has been made. The internal-combustion engine has acquired a definite position in the engineering world, and shares largely with the steam-engine in the power production of the world. Progress, however, has revealed conditions of unlooked-for advantage in the steam-engine which so far has not been attained in internal-combustion engines. The advent of the steam-turbine, developed by the genius and indefatigably hard work of the Hon. Sir Charles Parsons, has proved clearly that, for large powers, reciprocating pistons operating in cylinders must become a thing of the past.

In the early days of the compression internal-combustion engine (about 1880) the average efficiency of the steam-engines in use was very low. In Britain an average steam-engine of medium size would usually be found to convert only 5 per cent. of the total heat of the coal burned under the boiler into indicated work in the engine-cylinder. The best result obtained, even with large reciprocating steam-engines, about that time did not exceed 10 per cent., calculated in the same way. The early Otto cycle gas-engines of the same date converted 16 per cent. of the total heat of the coal-gas used into indicated power within the cylinder. As years went on this efficiency was greatly improved upon, and about 1910, internal-combustion engines of 15-in. diameter cylinder, when carefully made, could be relied upon to give an indicated thermal efficiency of 35 per cent., and in some experimental tests even so high as 40 per cent. has been obtained. At one time it was believed that as gas-engine cylinders increased in diameter, efficiencies would also increase, because of the diminished proportional surface causing less heat-loss from the hot flame to the enclosing walls. It was found, however, that increase beyond 15-in. cylinder diameter produced but little practical change in actual indicated thermal efficiency. Careful investigation into the phenomena of the gas-engine cylinder by many investigators, including the present author, proved conclusively that little gain could be expected from further increase of cylinder dimensions. Much scientific work had been done by the British Association Committee on Gaseous Explosions and by Committees of the Institution of Civil Engineers and of the Institution of Mechanical Engineers. These investigations clearly proved that definite properties of the working fluid limited the thermal possible efficiencies, so that if even the whole heat-flow through the sides of the cylinder be put an end to, only a moderate increase in indicated thermal efficiency would result. Distinct limits to increased thermal efficiency were shown to exist. The conditions, however, of heat-flow within the cylinder were more and more clearly understood, and were found to be greatly affected by cylinder dimensions; increased cylinders prejudicially affected the power of the cylinder-jacket and piston to dissipate the heat of the explosion and so tended to undue rise in wall temperature. In other words, it was found that the larger the cylinder became, the greater became the difficulty of preventing heat fractures in breech-ends, cylinders, liners, and pistons. It was speedily found that in the ordinary four-stroke or Otto cycle-engine, 22 in. to 24 in. was the safe limit of cylinder diameter for engines having unwatered pistons. Immediately these dimensions were exceeded, it became necessary to pump water through a hollow piston and also through the exhaust-valve, in order to keep down wall temperature and avoid fracture and pre-ignitions. Although watering a piston does not appear to be a formidable operation, yet it inevitably increases the weight of the piston and reciprocating parts of an engine, and so diminishes the possible piston-speed by increasing the stresses due to the acceleration and retardation. Engines as large as 51-in. diameter cylinder have been made, but the weight required per horse-power was very greatly increased. The law of similar structures shows clearly that for entirely similar engines of increasing cylinder dimensions, the weight per indicated horse-power increases directly with the cylinder diameter. This is true of steam- as well as of gas-engines, but the gas-engine is at a disadvantage because the ratio between maximum and mean available steam-pressure is much more favourable than that between maximum explosion and mean pressure; and, further, the double-acting steam-engine for a single piston produces two impulses per revolution, while a double-acting four-stroke engine requires two revolutions within which to produce two impulses. Accordingly, the weight of a gas-engine for a given power is greater than that of a steam-engine of equal cylinder diameter. A gas-engine is thus necessarily heavier than a steam-engine of the same power and cylinder dimensions. The law applies even with greater force to engines of the Diesel type, where pressures of compression of 500 lb. per square inch must be provided for, and a sufficient margin must be left to allow for even 1,000 lb. per square inch, due to explosive instead of constant-pressure ignition, which sometimes occurs, especially when starting. All these difficulties tended to restrict the commercially saleable internal-combustion engine to moderate powers.

On the Continent engine-builders favour large cylinder slow-running engines of great weight; but in England such engines never became really popular, and the great gas-engine trade of Britain has been built up on the basis of a cylinder not exceeding 24-in. diameter usually running with an unwatered piston and exhaust-valve. In England the multiple cylinder high-speed internal-combustion engine has had considerable success, and is now made by well-known engineering companies in sizes up to about 3,000 h.p. for one engine.

In reciprocating steam-engines for fast battleships and passenger steamers, the limit of weight for power was approached about 1895, and it became evident that, if higher speeds were required, some other method of obtaining motive power must be adopted. Sir Charles Parsons began his work on the land steam-turbine in 1884, and began experiments on the marine steam-turbine in 1894, and in a marvellously short time he passed from the engines of the "Turbinia," giving 2,000 shaft h.p., to the engines of the "Mauretania," giving 70,000 shaft h.p. It was speedily proved that the steam-turbine in various forms gave large powers within limitations of weight impossible by any other method. Powers of 100,000 h.p., for example, now frequently found in battle cruisers, such as the "Lion" and "Tiger," could not have been obtained from reciprocating steam-engines at all; still less could such powers have been obtained from internal-combustion engines of any type, whether gas or Diesel oil. Further improvements in gearing the steam-turbine to its propeller enabled the weight of the turbine to be greatly reduced, and its speed of rotation arranged for maximum efficiency, while allowing the speed of rotation of the propeller also to be arranged for maximum efficiency. Consequently the turbine became more and more economical.

In the early days of the small steam-turbine the steam consumption was large, but now Sir Charles Parsons is able to offer a large power turbine with a steam consumption as low as 9 lb. per shaft horse-power. In such an engine 20 per cent. of all the heat of the steam is converted into shaft horse-power, and with a boiler of ordinary efficiency this may be taken as giving a return of at least 15 per cent. of the whole heat of the fuel in useful work transmitted by the shaft. It was speedily found that these large turbine engines gave but little trouble in the engine-room compared with their reciprocating predecessors, and as a result the Parsons steam-turbine has become in a few years supreme in all battle fleets; indeed, if the total horse-power upon the seas of the world be taken as about 24,000,000 h.p., 8,000,000 h.p. is accounted for by the Parsons turbine.

The difficulties found to accompany increasing cylinder dimensions have thus limited the internal-combustion engine to comparatively small units; a 5,000-h.p. engine is considered very large for any form of gas-engine; a 5,000-h.p steam-turbine forms an ordinary unit for an electric light station engine. Obviously the internal-combustion engine must be considerably modified before it can equal the steam-turbine as a mechanism for producing large powers. As a machine for converting heat into work, the internal-combustion engine is still supreme; but engineers must now devote themselves to overcoming the mechanical difficulties of very large powers. It is possible to increase the thermal efficiency still further, but gain in that direction will not help us in our competition with the steam-turbine. So far as I can see, there is no hope of an indefinite increase in power using reciprocating pistons. Something must be done to introduce the rotary principle. Many attempts have been made to produce a gas-turbine, the most important recent attempt being that of Mr. Holzwarth, whose gas-turbine has been built by Messrs. Brown, Boveri and Co.; but, so far as I know, no success has yet been attained. The theory of the Holzwarth turbine in its form last known to me necessarily gives a somewhat low thermal efficiency; I have calculated it to be 15 per cent. of the heat of the working fluid, and in 1912 the extreme value claimed by Mr. Holzwarth was 23 per cent. Such results do not practically improve upon those of the largest steam-turbines.

Other methods, however, of dispensing with the reciprocating piston and cylinder are quite practicable. The large Humphrey pump described in the second Thomas Hawkesley Lecture dispenses with pistons, and utilises an explosion-chamber in which gases are compressed and ignited, and operate by throwing a heavy column of water into motion. This method has advantages, but it is necessarily heavy for a given power. It appears possible to use water in another manner by filling a chamber, exploding a compressed mixture above the water, and forcing the water through a jet to operate a turbine of the Pelton type. Arrangements would be made to allow for the varying velocity of the water due to fall of pressure by expansion, and it would be quite possible to obtain an efficiency between explosion-chamber and Pelton wheel of about 80 per cent. Such a turbine could be made to work using the same water repeatedly, and high efficiency combined with light weight is possible. A brake efficiency of 30 per cent. is possible. Experiments in this direction are worthy of consideration. Before such engines could compete for the highest powers reached by the steam-turbine, gas-producers must be considerably modified and improved. The Mond type producer using bituminous fuel has been fairly successful, but it depends largely for success on the recovery of ammonia, and this involves a bulky and heavy plant. This is

allowable in stationary installations, but for marine purposes much lighter and smaller producers would require to be designed capable of consuming bituminous fuel as completely as is done in a steam-boiler furnace, so that but little tar ever exists in the gas. If tar once gets into gas, an enormous scrubbing plant becomes necessary. Producers will require to be designed and experimented with which avoid the huge scrubbing plant required at present in all bituminous producers. With such producers and such engines a brake efficiency of 25 per cent. between fuel and Pelton wheel would not be difficult to obtain, and a 30 per cent. efficiency is quite possible.

With such mechanisms built in large power units, the power of Britain could be obtained for nearly one-third the present fuel consumption, and the work of the gas-engineer would thus materially aid in prolonging the coal life of Britain.

Progress of Indicated Thermal Efficiency.—So far the work of the engineer during the nineteenth and twentieth centuries has resulted in improving the indicated thermal efficiency from 3·8 per cent. obtained by the Boulton and Watt condensing low-pressure steam-engine to 35 and 40 per cent. obtained by explosion and constant pressure internal-combustion engines. The following table shows the progress very clearly :—

the engine. In comparing modern efficiencies, therefore, the steam-turbine shows 18½ per cent. heat conversion from the fuel against 28 per cent. heat conversion from fuel by gas-producer in the explosion gas-engines. From this it would appear that, even against the best steam-turbine, a very substantial advantage would be gained if internal-combustion engines were made of similarly high efficiency operating on the continuous rotating principle. This, however, is a matter for future development, and offers an excellent field for the young and ambitious engineer. At present the power in use by steam-turbine, both on sea and on land, is greatly in excess of that produced by stationary internal-combustion engines.

From what I have already said, it will be seen that engineers' efforts have been continuously directed for about 150 years towards increasing the thermal efficiency of their prime movers; and in this quest for greater economy they have adopted a working fluid, flame, much more difficult to deal with than the early working fluid, steam.

When fuel becomes more and more expensive as our coal supply becomes obviously lessened, organised attempts will be made to obtain economies which are not worth while so long as coal is cheap. Dr. Ferranti, in a presidential address to the Institution of Electrical Engineers, some time ago, dealt with the possibility

INDICATED THERMAL EFFICIENCY OF STEAM AND INTERNAL-COMBUSTION ENGINE.

		Indicated Efficiency. Per cent.
Steam.		
Boulton and Watt condensing low-pressure, about 1820		3·8
Cornish engine, about 1850		9·0
Triple expansion, about 1910		17·0
Parsons turbine, about 1914		23·0
Internal-Combustion.		
Lenoir, about 1860		4·0
Compression—Constant volume (two or four stroke)	1876	16·0
	1905	35·0
Compression—Constant pressure (Diesel), 1910		40·0

The indicated efficiency refers to the proportion of the total heat of the steam or working fluid given to the engine converted into indicated work. The indicated work obtained for 100 heat units in the fuel is, of course, less because of boiler and steam-pipe losses; and, where a gas-producer is used, because of gas-producer losses. Assuming a very favourable figure for the efficiency between the boiler and the steam-cylinder, 0·8, it will be seen that the indicated efficiency from the heat in the fuel in the case of the Boulton and Watt engine is only 3 per cent., and in the case of the explosion internal-combustion engine 28 per cent. Applying the same correction to the Parsons turbine, we get 18½ per cent. as the best result of heat conversion from fuel to the shaft horse-power of

of economising for both power and heat by the electric conversion and conveyance of all the fuel energy. He showed the advantages of large central stations distributing electric current at a very low price—he mentioned one-eighth of a penny per unit—applying this current for all the purposes of heating, lighting and motive power. So long as fuel is cheap, no doubt Dr. Ferranti's scheme might be usefully put into operation; but when fuel becomes really dear, too much heat is lost in the process of conversion into electric current. Central stations could be established in which steam-turbines were used for generating electric power, and where the exhaust-steam from the turbine was discharged at a pressure above that of the atmosphere, so as to maintain the temperature above 100° C.

Such turbines would not give the thermal efficiency now obtained by Parsons, because they would lack the long expansion used by him in his largest and most efficient machines. The exhaust heat, however, could be used for manufacturing purposes and for household heating in a city, and a combined heating and thermal engine could thus be produced whose theoretical efficiency was 100 per cent.; the only loss would be that due to conduction during distribution, but heat supply for a city for heating houses and for doing low temperature manufacturing work could be readily obtained from the waste heat of the steam-turbines at the central stations. A large part of the heat necessary for comfortable life and industry could thus be obtained. Where medium high temperatures were required, a gas of low calorific value could be distributed, and efficient furnace arrangements could be made to obtain the necessary temperatures with a maximum economy. The waste heat from such furnaces could also be used to raise steam to enable general heat distribution to be conducted. Under these conditions many chemical processes, such as smelting, would be conducted electrically, with only such weight of carbon as was necessary for the chemical reaction—the high temperature for the reaction would be given by the electric heating. By combinations of steam-power and internal-combustion engines and exhaust heating, using both engine exhaust and furnace discharge, great economies would be effected and fuel consumption would be very greatly reduced. Dwelling-houses would be heated by circulating steam or hot water up to a certain temperature, and the added radiant heat necessary for comfort would be obtained either electrically or by burning small quantities of coal or gas in suitable fires. Although such conditions favour a low efficiency use of steam for motive power, yet at a further scarcity price of fuel the high efficiency in the internal-combustion engine would find its field, because, broadly, a greater electrical heat and light could be obtained with a given fuel consumption, and the engine exhaust-gases would be at a higher temperature, and so have heat in a form available for a greater number of manufactures than the low temperature steam.

Future of Hydraulic Power.—Long before the final exhaustion of coal-pits, the increased expenditure necessary for heating and motive power would increase the pressure upon the hydraulic engineer, and undoubtedly much greater use would be made of water-power. I have already referred to Mr. Ellington's interesting calculation as to the total water-power of Britain determined by assuming all the rainfall to be available from a level of 500 ft. above the sea, except that portion required for the use of the population, and absorbed by vegetation and evaporation. Mr. Ellington calculates on this basis that 35 million horse-power would be available for 2,000 hours in the year. If this could be done, of course, Britain, except for marine purposes, could be independent of coal. This calculation, however, requires two-thirds of the area of England to be arranged at the high level of 500 ft. as a huge storage tank for rain-water, but with our present knowledge such an area is an engineering impossibility.

The future interaction of the world's three great prime movers—water, steam, and internal combustion—is very difficult to predict and appreciate. The effect, for example, of importation of coal from outside sources can hardly be predicted.

Whatever happens in the future, however, we may rest assured that hydraulic power will play a most important part, and that what has been called the "White Coal of the Mountains" will assume greater and greater importance with the increasing age of an industrialised world. In an able paper read at the Zürich Meeting of this Institution in 1911, Mr. L. Zodel concludes with this statement: "Members of the Institution of Mechanical Engineers are indeed the representatives *par excellence* of steam and steam power. Water-power, the 'White Coal of the Mountains,' will hardly be of much importance in their own country, compared with that all-powerful 'Black Queen of Energy' of which they have an abundance; but it may, indeed, play a very great part in the development of the resources of the vast colonial possessions composing the British Empire." Undoubtedly Mr. Zodel saw clearly; but as time goes on Britain itself will become more and more dependent on hydraulic power.

Meantime, by the application of high-efficiency engines, the use of all waste heat for domestic and industrial purposes, and the application of all available water-power, all on a large scale, the engineer may extend the industrial period in England to over one thousand years. Long before that period our dominions across the sea will have become huge nations exceeding the 100 million souls as predicted by Professor Seeley, and even a coal-less England will remain great and prosperous, the intellectual and strategic centre of a vast empire.

Altogether the engineers of the future have before them vitally important and interesting problems, and on the success of their work depends the future of our country—whether we can support, five hundred years hence, an industrial population of fifty millions, or an agricultural one of about twenty millions. Of our immediate future I have no fear. We shall assuredly uphold our liberty and independence, notwithstanding all the warlike efforts of the Germanic powers; but our distant future undoubtedly depends more on the efforts of engineers than on the labours of war or politics.

PEAT AS A SOURCE OF FUEL OIL.

The value of peat deposits as a source of fuel has been in part recognised for hundreds of years; but up to recent years it has been unrecognised, even by men of science, that the greater part of that value was wasted in the uses to which peat was put. Everyone who has travelled in Lanarkshire or in Kerry, to name but two of the many "peaty" regions of this kingdom, must have noticed the bare patches on the moors where "turf" has been cut, and the piles of peat turfs, resembling walls of brown unbaked bricks, which form the harvest of the moor. Sometimes these heaps belong to the landowner, sometimes to the peasantry, under rights of "turbary," which are dealt with in many old feus and leases and in statutes of the realm. Many of us have tried peat blocks as an economical addition to our coal fires, and those of us who have gardens have known the advantage of peat-dressing for the ground in which rhododendrons, for example, are planted. Quite recently the horticultural world has been stirred by the published accounts of the production of giant potatoes, flowers, and other vegetables and plants through the use of a fertiliser invented by Professor Bottomley, which is composed of prepared peat inoculated with a certain species of bacteria. This last use of peat represents highly specialised chemistry, as compared with the burning of crude peat blocks as fuel, or the mixing of crude peat with garden mould.

But, at the present juncture, when the difficulty of providing sufficient fuel to keep factories in full work, to supply motive power for ships of war or of commerce, for railway traction, and for domestic use, has presented a serious problem to the Governments of nearly every civilised State (not to speak of the Central States of Europe), the hitherto neglected quality of peat as a source of *highly refined* fuel, both solid and liquid, is the principal subject of interest in connection with this member of the great fuel-producing quartette of natural resources—wood, coal, oil, and peat.

A chief point in connection with peat, which is quite ignored by the general public, is that oil can be produced from it. Not only is it oil-producing, but the oil which can be and is now being distilled from common peat is one of the finest and purest oils that can be obtained for burning in quantities sufficient for any practical purpose. By the scientific treatment of peat, waste has now been almost completely abolished, and under the best process of preparation now available, the peat—previously macerated to break up the cells and dried in the form of briquettes—is converted into charcoal, ammonia, acetic acid, acetone, and methylic alcohol, as well as a gas which is used, without other fuel, to heat the retorts in which the distillation of the peat is carried out.

The charcoal which remains as the solid residuum, after the distillation of the peat briquettes, is of special value, in that it is not only of great heating power, but contains very little sulphur, a consideration which must impress anyone accustomed to the use of coal or coke. But, in this particular respect, the same advantage may be claimed for wood charcoal.

It is when we come to consider the oil produced in the chemical breaking-up of peat that the immense importance of the new discoveries with regard to the treatment of this natural product becomes apparent.

We have seen that oil is one of the specific results of the process. Now let us see what are the possibilities—realised in daily practice—of this oil. On further distillation it is itself subdivided into light oil, fuel oil, paraffin-wax, phenols, and pitch. The light oil is useful for internal-combustion engines; the paraffin-wax can be used for any purposes in which good paraffin-wax is generally employed; the pitch is just pitch, and is no more or less useful than other pitches. But the really notable resultant is the fuel oil. This is produced of a quality to meet the specification of the British Admiralty for naval fuel oil. More than that, it has an immense advantage which the Admiralty had not hitherto found it possible to include in its specification—it is, like the charcoal, practically devoid of sulphur.

The absence of sulphur in a fuel oil eminently suitable for naval engines is of immense importance to the health and comfort of the engineers and firemen in all cases, and of the whole crews in the case of destroyers and torpedo boats. The misery produced by the fumes emitted from the furnaces when the fuel contains an appreciable proportion of sulphur may readily be imagined by anyone who has himself burned sulphur in a room or store for the destruction of moth, and has opened the door to see how the stuff was burning. The lungs are suffocated, the eyes are inflamed by this penetrating smoke, and the human victim feels for a time that he would rather all the germs and moths should do their worst than that he should suffer such intense discomfort. Yet the stoker in the engine-room of a ship where sulphurous fuel is burnt—as it commonly is in small, swift-going naval craft—has to endure a similar discomfort nearly all the time, and this discomfort is often shared by half the crew who happen to be employed below deck, particularly in the space behind the engines. Not only does the health and efficiency of the human factor suffer much from sulphurous fumes from the oils hitherto in use in our Fleet, but the mechanical factor, the engines themselves, suffer a constant deterioration from the same cause. For every reason it is desirable that the oil containing the minimum of sulphur should be employed.

For naval purposes, therefore, not only on the score of efficiency as a fuel, but of economy of health and humanity, the peat oil is ideal. As to cost, the price at which it is being already produced is satisfactory, and the price at which it will be produced when large supplies are demanded, and great quantities of peat are brought under

treatment, will be considerably less than it is in the present circumstances of restricted manufacture.

As for the supply of the raw material it is, so far as anyone now living is concerned, or any likely demand within present purview, practically inexhaustible. It is true that, in spite of the fact that the neglect of all but the surface peat has, up till recently, left the lower masses to become richer year by year in those constituents from which oil is now being produced, there has been appalling waste during centuries past, if, indeed, that can truly be described as waste which was due to the absence of any possible means of prevention in the existing state of knowledge. But there should be waste no longer. The peat moors of Scotland, of Northern England, of Ireland and Wales, and of France, where vast tracts of peat lie about La Vendée, for instance, and in other regions well known to specialists in the new process, will almost certainly be brought under the control of men who will know how to develop to the utmost for national purposes these rich gifts of Nature hitherto so lavishly misused.

Dr. F. Mollwo Perkin, in his recent Cantor Lectures before the Royal Society of Arts on the "Production and Manufacture of Mineral Oils," added much to the general information accessible to the public on that question.

The waste of timber forests in England and the New World has been most lamentable, and in Western Europe France alone has, during a century past, cared or known how to treat her woodlands economically. That she will treat her peat moors economically now that their value is better understood seems certain. In any case, let us hope that as our oak forests were in the past depleted to provide material for our ships of war in the ages of "Wooden Walls," so, in this age of steel, our peat moors may be, not depleted, but scientifically treated, for the provision of motive power for those vessels which are doing so much to maintain that command of the seas which the frigates largely helped to secure.

W. H. Helm.

FOREST RESERVES OF CANADA.

According to a report just issued by the Canadian Government, the total area of the forest reserves of the Dominion in 1914 amounted to 152,935,593 acres, divided among the provinces as follows :—

Province.	Acres.
Quebec	107,997,513
Ontario	14,430,720
Manitoba	2,606,400
Saskatchewan	6,195,705
Alberta	16,813,376
British Columbia (in railway belt)	2,417,638
" " (outside of railway belt)	2,474,241

Besides the areas given for British Columbia, all lands west of the Cascades bearing more than 8,000 ft., board measure, of timber per acre, and all lands east of the Cascades bearing more than 5,000 ft., board measure, of timber per acre, are removed from entry.

It is stated that considerable care has been exercised in including in these reservations only lands which control watersheds, or which have been found unsuitable for agriculture.

USES OF THE PALMYRA PALM.

An unusual variety of uses has been found for the palmyra palm tree (*Borassus flabelliformis*), the list being so extensive that every part of the tree has been turned to some use.

Its five fibres are used in making various products, its timber is valuable, and it contributes to medicine and food supply.

The palmyra palm is tall, with a cylindrical stem. It grows all over tropical India, and is occasionally seen as far north as latitude 30°. It is especially abundant in all sandy tracts near the sea, on embankments around tanks, and in the mixed coconut and date-palm jungles of Bengal. The palmyra forests of Tinnevelli form a distinctive feature in the scenery of the Province. The greater part of the Indian export trade in palmyra goes through the port of Madras.

The five fibres include one about 2 ft. in length, which may be separated from the leaf stalks, and is used for making rope and twine, and sometimes for paper; a loose fibre, which surrounds the base of the leaf stalk; one called "tár," which may be prepared from the interior of the stem; a coir derived from the pericarp; and the fibrous materials of the leaves.

The leaf fibre is used especially in the manufacture of the basket-ware of Madras, and is put to a great variety of other uses by the natives. Fine strips of the leaves, especially prepared and dyed, are plaited into braids and worked up into fancy boxes, cigar cases, etc. At Diamond Harbour, near Calcutta, hats have for many years been made of this material and sold to European sailors.

According to a report by the United States Consul at Calcutta, a few years ago investigations were started in India with a view to ascertaining to what extent the cord-like fibres of the palmyra might be utilised in brush-making, as a substitute for the American "piassava" fibre and the Ceylon "kittul" (*Caryota urens*), but without much success, apparently, as imports into India during the year 1913-14 included 313,070 dozen brushes and brooms, with a total value of £42,500. The leaves are used for thatching huts, for making fans, and in Bengal long strips of the leaf are employed by the children as washable slates.

The timber of the palmyra is the most extensively used of all the palm family. It splits easily, but is said to be able to stand a greater cross-strain than any other known timber. It is used for boat-making, water-pipes, and various domestic purposes. A small export trade is done in the

wood for making walking-sticks, umbrella-handles, rulers, etc.

In medicine, the juice of the palmyra is used as a stimulant, and when freshly drawn and taken regularly acts as a laxative. The root is regarded as cooling, and the ash of the spathe is given for enlarged spleens.

In connection with its use as food it is stated that one-fourth of the inhabitants of Northern Ceylon are dependent on this tree for subsistence, and in Tinnevelli and various communities of India large proportions of the population are supported by it.

The most important food product is the juice obtained on tapping the flower stalk. This juice may be used fresh as a beverage or allowed to ferment, which it does after sunrise, and then becomes an intoxicating liquor. If this liquor is distilled, it becomes palm wine, and by destructive distillation a good vinegar is obtained.

The fresh juice may be boiled down into a sugar called jaggery, which is one of the chief sugars of South India, especially Tinnevilli. It is also an important source of sugar in Burma. The tapping does not injure the tree. The toddy drawer, climbing the tree, tightly binds the spathes with thongs to prevent their further opening, and then thoroughly bruises the embryo flower within to facilitate the exit of the juice.

This operation is repeated for several days, and on each occasion a thin slice is taken off the spathe to facilitate the running of the sap and to help prevent it bursting the bound spathe. About the eighth day the sap begins to exude into an earthen pot placed for the purpose. The pots are emptied twice a day, and a coating of lime inside the pot will prevent fermentation.

Four or five quarts per tree per day is the yield for four or five months. Once in every three years the sap-drawing process is omitted, as otherwise the tree would die. The tree begins to yield at fifteen years, and continues for about fifty years.

The female tree yields about twice as much sap as the male. Three quarts of this sap make one pound of sugar or jaggery. The sweetness of the Burmese bread is caused by the use of toddy juice as a yeast.

The tree flowers in March, and the young fruits are formed in April and May, ripening in July and August. The seeds are eaten as well as the fruit. A seed bed is prepared, and the nuts planted as close together as possible about June or July. At least fifty seeds are planted to the square yard, and in about four months are dug up. The nuts by that time have germinated, and the sprout or young seedling is eaten as a vegetable. The nut itself is broken open and the embryo within eaten dry or is made into a flour that is not unlike tapioca.

In normal times the gross value of a crop per acre, at ordinary market rate, ranges between £1,200 and £2,000.

The following figures, which were compiled by the Department of Statistics, Commercial Intelligence Department of Calcutta, from returns furnished by the collector of customs at Madras, show the quantities of palmyra fibre exported from the Madras Presidency during the last three fiscal years:—

Exported to	1912-13.	1913-14.	1914-15.

ENGINEERING NOTES.

Proposed Indian and Ceylon Railway Connection.—The extension of the narrow gauge of the main lines of India to the extremity of Rameswaram Island, and of the broad-gauge Ceylon State Railway to Talie-manar have been completed. There still remains, however, a break of about twenty miles in the railway connection, over which traffic is conveyed in ferry steamers, but, according to the Administration Report on the Railways of India for 1914–15, provisional plans have now been drawn up for filling this gap and completing the railway over Adam's Bridge. "The proposal is to construct a solid embankment or causeway on the islands and sandbanks of Adam's Bridge, from Danushkody Point on the Indian side to Talie-manar Point on the Ceylon side. About seven miles of this causeway would be built on the dry land of the various islands, and would consist of low banks of sand pitched with coral, presenting no difficulties in construction. The remaining thirteen miles through the sea would

be constructed on a double row of reinforced concrete piles driven into the sand, pitched at 10 ft. centres, and having their inner faces 14 ft. apart. The piles would be braced together longitudinally with light concrete arches and chains, and transversely with concrete ties, struts and chains. Behind them slabs of reinforced concrete would be slipped into position, the bottom slabs being sunk well into the sea bottom and the space enclosed by the slabs filled with sand. The top of the concrete work would be carried 6 ft. above high water, and the rails laid at that level. It is anticipated that the suspended sand brought up by the currents would settle on each side of the causeway and eventually link up Rameswaram and Manar Islands. The total cost of the causeway and the works at the two terminal points of the present railways is estimated at about 111 lakhs of rupees, equivalent at par to £740,000." It is to be hoped that this estimate will include the broad gauge and rectify the mistake made in carrying the narrow gauge into Southern India.

Railway Development in Nigeria.—This has been, states a recent consular report, as rapid in the last few years as in any part of West Africa. The railway system, which is controlled by the British Colonial Government, now extends nearly 800 miles into the interior. The ocean terminus is at Lagos, the main seaport of the colony. The main line runs in a north-easterly direction for 712 miles to Kano, the principal town in the Mohammedan States of Northern Nigeria. From Minna Junction is a branch south to Baro at the head of the permanently navigable section of the River Niger, while a second branch, opened a year ago, runs from Zavia to Bukeru, reaching rich tin deposits. The entire system is of 3 ft. 6 in. gauge.

A Notable Achievement in Wireless Telephony.—The transmission of speech over the 4,600 miles that separate Arlington, Virginia, from Honolulu is likely to rank as an important advance in the development of wireless telephony. Thanks to the ingenuity of various inventors there are ample means of getting a large amount of energy radiated from the antennæ at such frequencies as 50,000 periods per second, which are sufficiently high to prevent audible vibrations in the receiver, and yet capable, by their far less rapid variations in intensity, of transmitting articulate speech. The success of the recent experiments shows clearly that the difficult problem of wave telephony—the control of a sufficient amount of energy by the transmitting device—has been successfully solved, but by what means this has been done has not yet been disclosed. For several years past it has been possible to get a sufficient output of energy at the proper frequency, and the receiving apparatus is relatively a simple matter. To produce, however, a telephone transmitter capable of impressing the necessary modifications of current intensity on a large scale has proved to be a very troublesome matter. Obviously wave telephony over great distances will meet with the same difficulties as wireless telegraphy as regards the effects of atmospheric conditions, and yet it is a solution of many problems of transmission of intelligence. It makes it possible to hold communication with ships over the whole width of the Atlantic and with isolated islands. In as much as speech can be passed on from a wire line to a wireless section, and then again to the subscriber, one can imagine, for example, calling up a correspondent in Bermuda or the Azores as comfortably as across the street. Of course, messages sent out can, as far as we know at present, be heard by anybody who can tune in on the required frequency, which is inconvenient for some purposes. On the other hand, the receiving station can, with considerable success, limit its reception of messages to those coming from a particular station.

Geared Locomotives.—These engines have been very successful in hauling trains on steep gradients and in shunting yards with sharp curves. Geared locomotives were put into service some time ago by the Australian Oil Corporation on a gradient of 1 in 25. More recently two heavy geared locomotives have been purchased for shunting in Kansas City, where the curves and gradients are very severe, the latter varying from 1 in 20 to 1 in 14, on which a load of 170 tons can be hauled. The engines are of the "Shay" type, in which three inverted cylinders are mounted on one side of the firebox. To give flexibility of wheel-base, the engine and tender are mounted on three bogies, all the wheels of which are driven by the engine shaft through flexible couplings and bevel gearing, which permit free curving of the bogies. To allow for the position of the vertical engine, the boiler is offset from the centre line of the track. Each engine with its tender weighs 185 tons.

Tests of Reinforced-Concrete Fence Posts.—Six types of the above posts have been tested under the direction of the committee on signs, fences, and crossings of the American Railway Engineering Association. All posts were made of 1 : 2 : 4 concrete, using broken stone or gravel aggregate not more than ½ in. in size, and were about one year old when tested. Two round, one square, one half-round, one T-shaped, one triangular section were used, all 7 ft. long, all of tapering outline except the last. The reinforcement consisted of various sizes of steel wire or rods, and the lateral dimensions varied from 5 to 6½ in. at the base to 3 or 4½ in. at the top. Impact, cross-bending, and cantilever bending

tests were made. The best results in all cases were given by the round tapering posts, 5½ in. in diameter at the base and 4½ in. in diameter at the top, reinforced with six No. 8 wires. The other smaller circular post, reinforced with five wires, also gave very good results. The tests indicated that this form of post, with several reinforcing wires, or the T-form with three ¼ in. rods, was the strongest and most reliable.

Tall Concrete Poles.—Two reinforced-concrete poles, each 150 ft. high, have been in service over the old Welland Canal at St. Catharines, Ontario, for nine years. Canal rules required a standard clearance of 150 ft. They were found to be in excellent condition, showing no sign of distress. They were designed for a horizontal pull at the top of 2,000 lb., and the steel was considered at this pull to be stressed to its highest permissible limit, 30,000 lb. per square inch. The reinforcement at the bottom consists of four 2½ in. round rods—pins they might more properly be called were their length less. These are decreased in diameter as the stress decreases, the diameter at the top being ¾ in. The concrete is a 1 : 5 mixture, using gravel. Turnbuckles are used to join adjacent lengths, the ends of which are upset. Each pole weighs about 40 tons, and was erected with timber shear legs 96 ft. high, hitches being taken at three points, and the poles were hoisted in a manner similar to a gaff in a sailing vessel.

Three New Turbo-Generators.—The *Times* informs us that the generator portion of a new turbo-alternator, recently ordered by the Commonwealth Edison Company, of Chicago, is said to be the largest 60-cycle machine so far designed. It will be rated at 35,300 kilowatts at 85 per cent. power factor, and will produce three-phase current at 12,000 volts, the speed being 1,200 revolutions per minute. The turbine, of the straight Parsons type, will take steam at 220 lb. pressure and 200° superheat, and its design differs from the large Westinghouse machines, now at work in the Interborough station at New York, in that the entire unit will be placed on one shaft instead of being divided into two crossed compound machines. It is to be ready next autumn. There has recently been installed in the Lots Road generating station of the Underground Electric Railway, a 15,000 kilowatt turbo-alternator, constructed by Messrs. C. A. Parsons & Co. It runs at 1,000 revolutions per minute, and comprises two units, a high-pressure and low-pressure turbine being mounted on the same shaft, with bearings between them. After passing through the high-pressure section of the turbine the steam is led to the centre of the low-pressure unit, which is double bladed, and the exhaust takes place at each end, leading into two separate condensers. The Public Service Company of Northern Illinois, which is affiliated to the Commonwealth Company, has purchased a 10,000 kilowatt, 60-cycle turbo-generator, the turbine of which, of the Curtis type, is distinguished by the fact that its steam supply will have a pressure of 300 lb. per square inch, with a superheat of 200°.

GENERAL NOTES.

British Malaya.—An article under the above title, which appeared in the *Journal* of June 25th, 1915, under the name of George d'Almeida, Portuguese Consul in Singapore, has been found to be a reproduction word for word of an article entitled "Engineering in British Malaya: Position and Prospects," which was published in *Eastern Engineering* of February 19th, 1915. The article was received by the Secretary of the Society direct from Mr. d'Almeida (a Fellow of the Society); there was nothing to indicate that it was not an original contribution from him, and it was accordingly accepted and printed as such. This fact was discovered some months ago, and would have been announced at once, but it was felt that an opportunity should be given to the writer for explanation. No such explanation having been forthcoming, it is felt that the time has come for an apology to be offered to the proprietors of *Eastern Engineering* for an unwitting appropriation of their article.

Electricity in Mines.—The second part of the annual report of the Chief Inspector of Mines and Quarries for 1914, just issued as a Blue-book, shows that the number of electrically-driven coal-cutting machines in use in mines at the end of that year was 1,415, an increase of 108 over the number in use at the end of 1913. During the year nine fatal accidents definitely due to electricity were investigated. Five took place above and four below ground. The report gives the following numbers of persons killed by electric shock underground in coal mines:—1907, ten; 1908, twelve; 1909, thirteen; 1910, fifteen; 1911, nine; 1912, seven; 1913, thirteen; 1914, four; and says the figure for 1914, by comparison with 1913, is very satisfactory, considering that the horse-power of electric plant in use below ground increased by 13 per cent. According to the report the death-rate in mines per million tons of mineral raised was 4·37 during 1914, as compared with 4·91, the average for the decennial period 1905–14.

The German Cement Industry.—This industry has fared badly during the war, according to *Engineering*, and the Halberstadt Chamber of Commerce has, on its behalf, appealed to the military authorities to consider the Central German cement industry in connection with their requirements of cement in the occupied

enemy districts. The Central German cement works have an aggregate annual capacity of 5,000,000 barrels, and a capital of 20,000,000 marks. The export trade, which in ordinary conditions accounts for about two-thirds of the output, has entirely ceased, and the wants of the private building industry are small; during the year not one-fourth of the aggregate production has been sold. The adverse conditions from which the Cement Union suffers will probably continue after the war. For years to come remunerative trading will be handicapped by the forward sales of several works not belonging to the union. Amongst the unhappy Kartel agreements must be reckoned that with the blast-furnace cement works. The allowance of 10 pfennigs per barrel is out of all proportion to the harm done to the union by the manner in which the blast-furnace cement works undersell the union, and the position of the union is becoming so critical that the question of its dissolution calls for serious consideration.

Patent Office: Renumbering Specifications on Publication.—In order to give the public the advantage of having abridgments of specifications up to date while retaining their numerical sequence, applications for patents made subsequent to 1915 will be given new numbers when their complete specifications are accepted or become open to public inspection before acceptance. The new numbers will start with No. 100,001 (without any indication of date), and will supersede the original application numbers in all proceedings after acceptance of the complete specifications. It is intended in future to issue abridgments of specifications in the *Illustrated Official Journal* a few weeks later than that in which their acceptance or publication is advertised, so that they will be available for search purposes soon after the printed copies of the specifications are on sale; but, until the system is fully in force, they will only be issued when there are sufficient to make up a full sheet of sixteen pages. The present series of abridgments will run concurrently with the new series in the *Illustrated Official Journal* until April, 1917, when it will be entirely superseded.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

January 19. — Lawrence Chubb, "The Common Lands of London: the Story of their Preservation." Lord Farrer will preside.

January 26.—J. Arthur Hutton, Chairman of the British Cotton Growing Association, "The Effect of the War on Cotton Growing in the British Empire." Sir Daniel Morris, K.C.M.G., D.C.L., D.Sc., will preside.

February 2.—

February 9.—Professor J. A. Fleming, M.A., D.Sc., F.R.S., "The Organisation of Scientific Research." Dugald Clerk, D.Sc., F.R.S., Chairman of the Council, will preside.

February 16.—The Hon. Lady Parsons, "Women's Work during and after the War."

February 23.—Miss H. B. Hanson, M.D., B.S., D.P.H., "Serbia as seen by a Red Cross Worker."

March 1.—Charles Delchevalerie, "Belgian Literature."

Indian Section.

January 13. — Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., late Survey of India, "The Romance of Indian Surveys." Dugald Clerk, D.Sc., F.R.S., Chairman of the Council, will preside.

February 17.—C. A. Kincaid, C.V.O., Indian Civil Service (author of "Deccan Nursery Tales," "The Indian Heroes," "The Tale of a Tulsi Plant," etc.), "The Saints of Pandharpur." Lieut.-Colonel Sir David W. K. Barr, K.C.S.I., will preside.

March 16.— Professor Wyndham R. Dunstan, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India."

Dates to be hereafter announced:—

R. W. Seton-Watson, D.Litt., "The Balkan Problem."

Charles R. Darling, A.R.C.Sc.I., F.I.C., "Optical Appliances in Warfare."

Rev. P. H. Ditchfield, "The England of Shakespeare."

W. A. Craigie, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

Victor Horta, Directeur de l'Académie Royale des Beaux-Arts de la Ville de Bruxelles, "Belgian Architecture."

Professor T. G. Masaryk, "The Slavonic Peoples."

G. P. Baker, "Hindu Hand-painted Calicoes of the Seventeenth and Eighteenth Centuries, and their Influence on the Tinctorial Arts of Europe."

S. Charles Phillips, M.S.C.I., "Paper Supplies as affected by the War."

SIR DANIEL MORRIS, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland."

JAMES MACKENNA, M.A., I.C.S. (Deputy Commissioner, Myaungmyn, Burma, and designated Agricultural Adviser to the Government of India), "Scientific Agriculture in India."

INDIAN SECTION.

Thursday afternoons at 4.30 p m.:—

April 6, May 18.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

February 1, March 7, May 2.

CANTOR LECTURES.

Monday afternoons at 4.30 p.m.:—

J. ERSKINE-MURRAY, D.Sc., F.R.S.E., M.I.E.E., "Vibrations, Waves, and Resonance." Four Lectures.

May 1, 8, 15, 22.

FOTHERGILL LECTURES.

Monday afternoons, at 4.30 p.m.:—

REV. DR. HERBERT WEST, D.D., A.R.I.B.A. (author of "Gothic Architecture in England and France"), "National and Historic Buildings in the War Zone: their Beauty and their Ruin." Three Lectures.

February 7, 14, 21.

EDWARD A. REEVES, F.R.A.S., Map Curator, Royal Geographical Society, "Surveying." Three Lectures.

March 27, April 3, 10.

JUVENILE LECTURE.

A lecture by Mr. James Swinburne, F.R.S., on "The Science of some Toys," will be given on Wednesday afternoon, January 12, at 3 p.m.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 10...Electrical Engineers, Institution of (Local Section), Mining Institute, Newcastle, 7.30 p.m. Mr. J. R. Beard, "The Design of High-Pressure Distribution Systems."

Surveyors' Institution, 12, Great George-street, S.W., 5 p.m. Mr. R. M. Kearns, "Notes on Reinforced Concrete."

Geographical Society, Burlington-gardens, W., 8.30 p.m. Sir A. Evans, "The Adriatic Slavs and their relation to the future Overland Route to Constantinople."

TUESDAY, JANUARY 11...Electrical Engineers, Institution of (Scottish Section), 207, Bath-street, Glasgow, 7.30 p.m. Professor M. Maclean and Mr. D. J. MacKellar, "Distribution and Rise of Temperature in Field Coils."

(Manchester Section.) 17, Albert-square, 7.30 p.m., Professor M. Walker, "The Predetermination of the Performance of Dynamo Electric Machinery."

Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. J. S. Dow, "Some Principles in Industrial Lighting, with special reference to the Report of the Departmental Committee on Lighting in Factories and Workshops."

Asiatic Society, 22, Albemarle-street, W., 4 p.m. Mr. V. A. Smith, "Akbar, the Great Mogul, 1542-1605."

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Mr. F. W. Carter, "The Electric Locomotive."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Paper by Messrs. F. F. Renwick and Olaf Bloch.

Marine Engineers, Institute of, The Minories, Tower-hill, E., 7 p.m. Mr. J. H. Thompson, "Power-Driven Tools on Board Ship."

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. Dr. V. Cornish, "The Strategic Geography of the War in relation to the British Empire."

WEDNESDAY, JANUARY 12...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 3 p.m. (Juvenile Lecture.) Mr. J. Swinburne, "The Science of some Toys."

Automobile Engineers, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. G. W. Watson, "Back Axles."

Electrical Engineers, Institution of (Yorkshire Section), Philosophical Hall, Leeds, 7 p.m. Mr. J. R. Beard, "The Design of High-Pressure Distribution Systems."

Japan Society, 20, Hanover-square, W., 3.30 p.m. Dr. Suzuki, "The Japanese Red Cross."

University of London, King's College, Strand, W.C., 5.15 p.m. Professor W. B. Bottomley, "The War and the Food Supply."

THURSDAY, JANUARY 13...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Colonel Sir Thomas H. Holdich, "The Romance of Indian Surveys."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Professor M. Walker, "The Predetermination of the Performance of Dynamo Electric Machinery."

FRIDAY, JANUARY 14...Malacological Society, Burlington House, W., 7 p.m. 1. Rev. A H. Cooke, "The Operculum of the genus *Bursa* (*Ranella*)." 2. Mr. E. A. Smith, "On the shells of the South African species of Sepiidæ." 3. Mr. A. Reynell, "On a volume of plates prepared by Rackett for the second edition of Pulteney's 'Dorsetshire Shells' in Hutchin's 'History of Dorset'; on Lovell Reeve's 'Elements of Conchology,' with some dates of publication."

Astronomical Society, Burlington House, 5 p.m.

Corrections.—Mr. W. W. Starmer asks that the following corrections be made in the report of his reply to questions asked after his paper on "Carillons and Chimes," reported on page 98 of the *Journal* of December 17th last:—

It was stated that there was a carillon at Liverpool. For the word "Liverpool" read "Loughborough."

In the sentence "He had heard it ['God save the King!'] played, and as the players had not the leading note in the right part of the scale they took it up several notes," for the words "several notes" read "a seventh."

In the sentence "If a bell had one series of harmonic terms," etc., for the word "terms" read "tones."

Journal of the Royal Society of Arts.

No. 3,295. VOL. LXIV.

FRIDAY, JANUARY 14, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 19th, 4.30 p.m. (Ordinary Meeting.) LAWRENCE CHUBB, "The Common Lands of London: the Story of their Preservation." LORD FARRER will preside.

Further particulars of the Society's meetings will be found at the end of this number.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s.* 6*d.* each, on application to the Secretary.

JUVENILE LECTURE.

On Wednesday afternoon, January 12th, Mr. James Swinburne, F.R.S., delivered the second Juvenile Lecture, the subject being "The Science of some Toys."

Mr. Swinburne said that the resolution of forces explained such toys as the kite and the sailing-boat in their elementary forms. This simple conception could then be applied to explain the main principles of the spinning-top and the more elaborate gyrostat. The gyrostat was used as a compass for steadying ships at sea, in the monorail, for steering torpedoes, and would probably be used eventually in aeroplanes. It had also been used for gunnery at sea. The earth might be regarded as a large gyrostat.

The bird-warbler showed the production of sound at varying pitch as the length of the little pipe altered. From this the propagation of sound might be considered, and how its velocity depended on the density and elasticity of the medium. The gramophone, used as a recording instrument, might be considered as analogous to the human ear, in something the same way as the camera resembled the eye. The sound coming in worked a diaphragm instead of a drumskin, and this worked a little lever which made a trace. For the real ear the drumskin worked little bones, which communicated the disturbances to the fibres of Corti. These fibres not only judged pitch, but they selected. In addition, they were affected by partial tones, so that the ear distinguished tone characteristics. These partials were due to each tone being made up as if of a simple tone with others superposed. The superposed tones were due to the instruments that produced them. So was the pitch. Organ pipes gave an extraordinary variety of tone characters, though there are only two kinds, flue and reed. The pitch depended on the velocity of sound and the length; the character on the mouthpiece and diameter in flue pipes, and the reed and tube in reed pipes. (Specimen pipes from an organ were sounded, varying from a tuba to a viole d'amour.)

A great deal had been written—at least in other countries—about the æsthetics of music, but without very much result. All ideas based on discussing the mental effects of chords one by one, or purely on the symmetry of form, as if music were like architecture, broke down in view of the effect of a gramophone run backwards. Music heard backwards sounded quite meaningless. But the chords and the symmetry were not altered.

On the motion of the Chairman a hearty vote of thanks was accorded to Mr. Swinburne for his interesting lecture, and the meeting terminated.

THE URALSK PROVINCE AND ITS OILFIELDS.*

In the last few years a good deal of interest has been aroused in an oil-bearing region which, it is widely believed, is destined to play an important part in supplying the future demands of the Russian Empire for petroleum and its products.

For some time past travellers and explorers have reported exudations of oil and gas, occurrences of asphalt, and other surface indications of petroleum, at various points in the tract known as the Kirghiz Steppes. These points have been located on maps, some fairly accurately, others far from correctly. This is partly due to the rarity, over a great part of the area, of landmarks of any kind, with regard to which the position of the observed occurrences may be described, and partly to the fact that the available maps of the region were not very accurate. In some parts of the steppe, the only possible points of reference are the tombs erected by the nomadic Kirghiz to their deceased saints, and a good deal of doubt seems to have existed about the correct naming of these places, adding to the difficulties of the explorers and cartographers.

Many of these localities have received more or less study from geologists and other experts, often by means of shallow pits and borings, since visible indications of the geological structure are as scanty as the landmarks. Various hypotheses as to the structure and the age of the beds have been advanced, in some cases backed by insufficient evidence or by no evidence at all, and, with the exception of a few areas which have been carefully investigated for commercial purposes, the geology of the region is little known as yet, whilst, owing to its great area, its wildness, and the sparseness of the population, it is probable that there are within its bounds indications of petroleum which have not yet been recorded. . . .

Roughly speaking, the reported signs of petroleum lie between the 51st and the 46th parallels of north latitude, and the 49th and 58th of east longitude. It will be seen that they are distributed over a very large part of the Uralsk Province. To get some sort of an idea of the extent of country involved, we may take a line from the point where the west boundary of the province reaches the Caspian shore, following this boundary northwards to the town of Alexandrovsk Gai, which lies just outside Uralsk, thence east to a point near the town of Temir, again south to Murtuk, and finally in a south-westerly direction, following more or less the course of the Emba River to the sea again, the southern boundary being, of course, the coast.

The area of this figure is, roughly speaking, some 60,000 square miles, somewhat greater than that of England and Wales. Evidences of oil are found all round outside these limits, and there is marked on this map a place called Djusa, in Turgai Province, which has attracted much attention of late, but, as we are considering the Uralsk Province particularly, we must draw the line somewhere.

In case these figures might lead astray persons of an enterprising and speculative disposition, let us emphasise the fact that we are not stating the dimensions of an oilfield, or of proven oil-bearing territory, but are merely noting that over this large area fairly frequent indications of petroleum occur.

Physical Features, Climate, etc.

The level of the Caspian Sea is 84 ft. below that of the Black Sea, and round its shores, also below sea-level, lies a zone of land, of greater or less width according to its inclination. By far the largest area of depression is that on the north, extending from the Volga to east of the Emba River, forming a belt of varying width. If a contour line be drawn, representing the datum line, ocean level, it will be seen that in general the part of this region north of lat. 50° is above, whilst that south of the lat. 50° is below it. In the eastern part of the area, however, where the ground rises more rapidly, this contour line turns sharply southwards.

Travelling inland from the shore of the Caspian Sea, a great plain is traversed, whose gentle rise northward is imperceptible. This same gentle inclination of the plain continues southwards into the sea for some miles. The coast-line is thus ill-defined, and consists of a belt of swampy land. Differences of level of a few feet in the surface of the sea cause the water to advance or retreat for a considerable distance. There are, it is true, no tides in the Caspian, but differences of level of four feet, and sometimes it is stated even of eight feet, are caused by the winds piling up the water in one direction or another, while other causes are differences of barometric pressure in the north and south ends of the Caspian, and also any conditions which disturb the equilibrium normally existing between loss by evaporation on the one hand, and the supply of water from rivers and rain on the other.

Returning to the land, the plain is, generally speaking, absolutely flat and featureless, every hollow having been filled and every prominence covered by the deposits of the Caspian Sea during the period, geologically very recent, during which it extended far beyond its present limits. The soil is formed of sandy clays, or clayey sands, often heavily charged with salt. In other places are encountered considerable accumulations of loose sand, due to the action of the wind. Other areas are swampy, while

* Extracted from a paper read by F. A. Holiday, A.R.C.Sc., F.G.S., M.A.I.M.E., before the Institution of Petroleum Technologists.

there are a number of salt lakes, many of which are dried up by the heat of summer, when their beds are covered with a glistening white deposit of salt.

Frequently one may travel for miles without ever meeting the smallest landmark of any kind, except here and there a tomb erected by the Kirghiz nomads.

Trees are entirely wanting on these steppes, excepting where they have been planted by the sides of rivers. Scanty grass and a small shrub are to be found over a great part of the area, on which the herds of the Kirghiz feed as they travel. In favoured spots, near streams and fresh water, there is greater abundance of herbage, whilst other places, where excess of salt or of loose sand renders vegetable life impossible, are quite desert.

Further northward and north-eastward, with increase of elevation the land becomes a plateau through which the rivers flow in deep gorges. The northern boundary of this tract of country is formed by the highlands near the Ural River, belonging to the Obscii Syrt. In the north-east and east, highlands rise gradually to the Mugodjar hills, and in the south-east corner the boundary is the elevated Ust-Urt plateau. On the west the plain stretches into the steppes of European Russia.

Thus in the east and north-east the highland is nearer the sea than in the west. The town of Uilsk is considerably higher than Uralsk, although the latter lies considerably to the north-west of it, and the general slope of the whole region appears to be from north-east down towards south-west.

The principal river in the Uralsk Province is, of course, the River Ural, which, rising in the Ural Mountains in Orenburg and travelling a little south of westward from the city of Orenburg to Uralsk, turns and flows practically due south to the Caspian Sea, into which it empties itself at Guriev.

Next in importance is the River Emba in the east, which rises near the Mugodjar hills, and, receiving as tributaries the Temir and some other unimportant streams, divides some fifty versts from the Caspian, the north or principal branch reaching the sea at the fishing village of Jila Cosa. It is a shallow river, and in some summers does not discharge directly into the sea, losing itself in swampy ground. Between the Ural and the Emba lie the rivers Uil and Sagiz, which have their sources in the highland to the north-east of the petroliferous area. The former disappears among the sands of Taisuekan and some small lakes near Kazil Kuga Bazar, and the latter in the lowlands near the Caspian to the north of Rakusha.

There are other unimportant rivers which all terminate in the same vague way.

West of Guriev, in the Cossack lands, a few small streams find their way into the Caspian, one in particular, the Bolshoi Baksa, which is really a branch of the Ural, passes the village of Novo-Bogatinsk, which is getting known as a probable oil-centre, and furnishes good water with fresh-water fishes as far as a dam near the village. Sometimes it runs dry, but water is obtained by making holes in its sandy bed. Below this dam it, as well as the other streams between it and Guriev, is apt to be brackish. Their degree of salinity, small at any time, is variable. When they are bringing down but little water they are invaded by the Caspian Sea. The Caspian waters, however, are only moderately saline, especially in the shallow northern parts, which are much influenced by the great volume of water discharged by the Volga and the Ural. Although the streams between Guriev and Novo-Bogatinsk are small, their importance is enhanced by the fact that they occur in a district promising to prove rich in oil.

As the climate of this region is quite continental, a considerable range of temperature is experienced in the course of the year, the summer and winter temperatures being respectively higher and lower than the mean temperature of its latitude for these seasons. . . .

There is thus a wide range of temperature, not only during the year, but also in the course of twenty-four hours, for often out on the steppes cold nights follow the hottest days in summer.

This region forms the north-western extremity of the great tract of low rainfall which stretches for some distance through Central Asia. At Guriev the rainfall is only some 17 cm. annually, but at Uralsk it is about 34 cm., the seasons of greatest rainfall at these two places being the spring and the summer respectively. In the Guriev district there is also a good deal of rain in the autumn.

There is a great deal of wind on the steppes, the prevailing winds coming from the north or north-east in winter, and the south and south-west in summer.

Taking it all round, however, the climate is not a bad one, and many Europeans live at Guriev and the adjoining centres in comparative comfort all the year round, with the exception, perhaps, of a few of the hottest days in the summer.

Navigation in the North Caspian and the Volga is closed by frost about the middle of November, to reopen in May.

Inhabitants, Towns, etc.

The Uralsk Province has a total area of about 125,000 square miles (284,400 square versts), and is about 3 per cent. larger than the British Isles. It is divided into two parts by the Ural River. All the land on the western side of the river, together with a narrow strip on the eastern side, is the territory of the Ural Cossacks; it amounts to some 27,250 square miles,

and is nearly as big as Scotland. The land on the east belongs to the Crown. The population of this great province was estimated a few years ago at about 750,000 souls, of whom nearly two-thirds were described as nomadic.

At this rate the "elbow-room" works out at about 106 acres per head of the population. Other estimates place the population rather higher, but it is impossible to get the correct figures for the wandering Kirghiz. The cattle of various kinds amounted at the same estimate to some 4,000,000, including horses, 370,000; camels, 188,000; oxen, 780,000; sheep, 2,470,000, etc. Occasional plagues make great havoc of the cattle.

The original inhabitants of this region are the Kirghiz, an essentially nomadic race, who travel with their herds of camels, horses, sheep and goats, which manage to subsist on the scanty grass covering the steppes.

These people live in dome-shaped tents, made of a light wooden frame covered with camel-skins or other suitable material, and having a circular hole at the top which can be closed if desired. The tents, which look very rough, are surprisingly comfortable, affording a considerable amount of shelter from the blazing sun as well as from the cold winds. The floor is partly covered with skins, rugs, and sometimes with beautiful Oriental carpets, but part of it is left bare, and on this the fire is made. The tents are easily erected and taken down, and with two or three trunks, containing a few simple household utensils, form the whole luggage of a Kirghiz family. The typical mode of transport is, of course, on the camel's back, but in these days many Kirghiz have carts.

Water is scarce in these steppes, but the Kirghiz have nevertheless discovered many spots where it may be had free, or nearly free, from salt, and here they have dug wells, which enable them to supply their needs when travelling. As the hot weather dries up the lower part of the steppe, they move northward to places where there is a better supply of water and pasture.

The entire absence of trees causes the fuel problem to be somewhat acute, and though, like the Arabs, they collect the dried manure of their herds for cooking and heating purposes, wood is greatly prized by them. The advent of Western civilisation furnished them with a certain amount of firewood in the shape of telegraph poles and the stakes used to mark out claims. They have, however, learnt by now to respect the former, though not, in most cases, the latter.

Far out in the steppes one meets with groups of Kirghiz who are still very primitive, but contact with the Russians has altered those who approach the inhabited districts. They earn money, or its equivalent in goods, by trade in cattle and fish, by transporting goods for the oil companies, and by manual labour, and thus raise their standard of living. Many of them settle in the villages, especially in the winter, though they mostly wander in summer.

As a race they are not particularly strong or energetic, but intelligent. Like many Asiatics they take kindly to study, and those that adopt the more settled life and attend schools, etc., make good pupils, but if they try to continue their higher education in Russian towns are liable to break down with pulmonary consumption, for they are essentially a nomadic, open-air race. Even in their native steppes they are frequently attacked by a terrible plague, which attacks the lungs, is exceedingly epidemic, and always rapidly fatal. The Cossacks and Europeans are not nearly so susceptible to this malady, although not altogether immune; but when the plague is about, the wandering groups of Kirghiz are not allowed to approach the towns, so that the white people are seldom attacked by it.

Regarded as workmen for the oilfields, the Kirghiz, although, as already said, somewhat lacking in strength and energy, are, on the other hand, sober and orderly. One is never sure of keeping a Kirghiz workman, as he generally has a family and some cattle wandering about somewhere, and is liable to go off and join them at short notice.

The ruling race in this country are, of course, the Ural Cossacks. They are a military race from their boyhood up, and have numerous privileges in return for their services. On their own lands the Cossacks have exclusive rights to all vegetable produce, and to all grazing, all game, and all fish, and no one else has the right to use the rivers in any way without their permission, and they are very jealous of their privileges. The Ural River is a great source of wealth to them. It is abundantly stocked with fish and great quantities of caviare are obtained, which forms a valuable export. In the fish-breeding season any sort of boating on the river is most strictly forbidden, and at one time this caused some difficulty to the oil companies at Guriev, who wanted to keep their communications open, across the Ural, with Dos-Sor and their other properties on the east side. At present there is a bridge on pontoons across the river.

The Cossacks are a sturdy race and capable of making good workmen; they are, however, as may be imagined, somewhat independent, and before the edict abolishing the vodka monopoly there was a great deal of insobriety in all the towns and villages.

The principal town of the whole region is Uralsk, with some 45,000 inhabitants; Cossacks and other Russians, Kirghiz and Tartars are all to be found there. There are many good buildings and fairly good hotel accommodation. The Governor of the Uralsk Province resides

there. All business connected with exploring and mining rights on the Cossack lands west of the River Ural must be conducted here with the Cossack authorities.

Along the Ural River between Uralsk and Guriev are a number of small towns, the chief being Lbishchensk (4,000 inhabitants) and Kalmikovsk (2,000 inhabitants).

Guriev, at the mouth of the Ural River, with 11,000 inhabitants, is the chief town after Uralsk. It has up to now served as the headquarters of the various companies operating in the oilfields. As long as the Volga and the north of the Caspian Sea are open to navigation, it may be reached from Astrakhan by sea. Astrakhan itself is reached from the interior of Russia, either by railroad or by the excellent steamers running on the Volga. The service between Astrakhan and Guriev is performed by two companies, the Eastern (Vostockki) and the Gurievski. The journey is accomplished under favourable conditions in thirty-six hours, though in bad weather, or if, as is often the case, heavy barges are towed behind the steamer, the voyage takes considerably longer. Up till two or three years ago the service was very bad, being performed by a couple of small boats, which, if the wind got rough, would put in to the shallows near the coast and anchor in a few feet of water, but lately there has been much improvement.

The landing at Guriev is somewhat difficult on account of the extreme shallowness of the water, especially when the wind blows the sea away from the shore. Travellers leave the steamer in a tug, which takes them as far as possible. The final stage of the journey is made in carts, which drive out to meet the tugs or barges, and take the passengers, sitting on their luggage, through the shallow water to the shore.

If navigation is not open on the Caspian, the journey to Guriev must be made *viâ* Uralsk, which itself is reached from the interior by rail, after crossing the Volga by ferry at Saratov. Guriev is then reached by the road, which nearly follows the course of the River Ural, with post-horses and carts (or tarantasses), or, if there is snow, with sledges. The distance by road is 330 miles, and there are twenty-three stations at the Cossack towns along the river, already referred to, at which horses are changed, sometimes with considerable delay. The journey is very uncomfortable, and its length depends on the ability of the traveller to endure the joltings and fatigue without resting. It is possible to travel night and day, as horses and drivers are continually changed, but four or five days are frequently taken over the journey. With a good automobile and with fairly dry weather this road may be covered in less than two days, the journey from Saratov to Guriev *viâ* Uralsk under these conditions being quicker than that *viâ* Astrakhan.

The steamboat companies are not recognised as mail carriers, and letters posted in Guriev for Astrakhan are taken by the postchaise right up to Uralsk or down again by rail to Astrakhan. This, the only route in winter, means great loss of time in summer.

In the spring of 1914 the Ural River overflowed its banks, and while part of the journey from Uralsk could be performed by road, crossing temporary lakes and streams on rafts, the lower country was completely flooded, and the last two days of the journey had to be performed in boats. As this inundation extended for some distance on either side of the river quite down to the sea, Guriev was an island for the time being. It should be pointed out that this state of things was altogether exceptional, nothing like it having been seen before by the living inhabitants of the country.

In the east of the province is the town of Temir, near the Orenburg-Tashkend Railway. It may be reached by road *viâ* Uilsk from Uralsk or Kalmikovsk. The roads are not made, but are only tracks across the steppe. On several of them there are small stations at which horses may be changed, but the accommodation on the others is inferior to that on the Uralsk-Guriev route.

Dos-Sor, at which there was no settlement a few years ago, now ranks as one of the towns of the province; there is, of course, no post-road there, but the oil companies provide a few water-stations between Dos-Sor and Guriev for their own traffic.

Besides the principal towns and villages, there are a few small settlements scattered about the steppe, some with a mixed population, and some inhabited by Kirghiz and Tartars only, with perhaps one Cossack as the representative of the Government.

Petroleum Mining Claims.

Prospecting or exploration claims are called zaiavkas. The word zaiavka means declaration or testimony, but is also used to denote a claim or plot of land.

This territory is attached to the Astrakhan mining district, and is under the jurisdiction of the Southern Mining Department at Novotcherkask.

The granting of zaiavkas for oil-prospecting is carried out by the Department of Agriculture and State Domains, whose headquarters are at Samara; claims on the Cossack lands west of the Ural River are granted at Uralsk.

The prospector must declare that he has placed claim-posts in such and such places, stating accurately their position with regard to some definite point of reference.

Each claim-post is the centre of a zaiavka, which has an area of 37½ desiatines, or about 101 acres, and forms a square whose sides measure 300 sagens, or about 700 yards. The certificate gives the right to explore the ground

in any manner, including drilling, for two years, before the end of which period allotments, or otvods, may be selected. Not more than 10 desiatines may be taken up in any one zaiavka, rather more than a quarter of the original prospecting claim; the remainder of the zaiavka reverts to the authorities, to deal with as they think fit.

When once an otvod is selected, the holders may keep it as long as they like, provided that they produce oil, on a yearly payment of Rs.20 per desiatine.

Zaiavka-holders cannot market any oil they may produce until they take out an otvod.

It is obvious that during the two years' tenure of a zaiavka every effort must be made to obtain a knowledge of the structure of the ground, in order to select the otvods in the best possible position. In places where geological data can be obtained from a superficial examination this may be comparatively easy, but unfortunately, over a great part of this region, such knowledge can only be obtained by digging pits or by trial drilling, which requires time and money.

In many cases the prospector who has staked out his claims in a hurry round a seepage (which is often the only indication of the underground conditions), in order to forestall possible rivals, is not the representative of a group who are in a position to carry out costly operations.

He, or his employers, may be obliged to look or capitalists or company promoters who will be in a position to develop the property. Much time may elapse, and there is a danger that, by the time the zaiavkas are in the hands of those willing and able to develop them, the two years' tenure is drawing to a close, and finally the otvods may have to be selected before sufficient evidence has been obtained.

There has, unfortunately, been a great deal of wild speculation in the Ural region during the last few years.

Thousands upon thousands of zaiavkas have been taken up, sometimes in places where there appears to be no possible reason for their selection. In many cases they have been hawked about, no exploratory work proceeding in the meantime, and their value gradually decreasing as the end of the two years' period drew nearer. An enormous amount of work has been thrown on the mining authorities, not only as regards the clerical labour involved in the granting of certificates, but also in the field, where their surveyors have had some difficulty in coping with their task. In some places trouble and confusion have occurred over the position of the claims, overlapping occurring, and this not necessarily through the deliberate "jumping" of claims.

For instance A, taking a certain Kirghiz tomb as his reference point, marks out a number of claims to the east of it. He then departs, and the Kirghiz promptly take his claim-posts for firewood. Soon afterwards B, starting from another tomb lying a few versts east of that of A, marks out claims to the west of it, and overlaps A's zaiavkas. Through inaccuracies in maps, or mistakes in naming, the tombs may be thought to be further apart than they really are, and A and B may meet later and compare plans, and honestly believe that they have not infringed on one another's rights. The geography of the country is getting better known now, but much confusion has arisen from these causes.

While much money has been wasted in rash speculation with zaiavkas on which never a stroke of work has been done, real hardship has been caused in other cases to genuine enterprises which have been nipped in the bud or held up by the outbreak of war, and it is to be hoped that when peace is restored the Russian authorities will deal with these cases in a liberal spirit.

Development.

Although special privileges to encourage the commercial exploration of this country were granted as early as 1899, its development has only been begun within the last few years.

Firstly, in 1899, exclusive rights to search for oil in six volosts (or districts) were granted to Lehmann and the heirs of Doppelmayer. These privileges were renewed several times until near the end of 1909. Several scientific men studied the field during this period, notably Messrs. Lebedev and Nikitin. Towards the end of the period Mr. Stahkoev joined the other capitalists. A good deal of exploration work was done, especially at Iskene, Dos-Sor, Karaton and Karatchungul. At Dos-Sor a number of wells were sunk by Messrs. Lehmann and Stahkeev, and some oil was obtained at moderate depths, but in the light of later work it is evident that none of these wells were deep enough to test the locality thoroughly—a mistake often made in prospecting. At Iskene oil was found, though not in large quantities, at various depths —75 ft., 170 ft., 190 ft., 490 ft.

At Karaton oil was encountered at various depths, a number of small shows being found at from 30 ft. to 60 ft., as well as at lower horizons. At Karatchungul several wells worthy of remark were drilled. In one in particular oil was struck at 143 ft., and spouted somewhat intermittently 90,000 poods in three days, and continued to flow at intervals, for some time giving, it is stated, some 300,000 poods. At this point gypsum was met with, followed by clay. But the most interesting point is that in another well, where oil was met at 37 ft. (200 poods a day) and at 126 ft. (130 poods a day), below the latter point a great thickness of gypsum and rock-salt was traversed, and at a depth of 1,000 ft., still in gypsum, evidences of petroleum were again encountered. Nevertheless, the commercial development of the

district was delayed. From the end of 1909 the concession was renewed until November 12th, 1912. An English company, the Ural-Caspian Oil Corporation, was formed, and took over all the privileges of the concession, to which two more volosts had been added (giving the territory the well-known form which appears on the maps), these privileges including a valuable rebate of half the excise duty on refined oils for the first eight million poods, this rebate holding good for five years from January, 1910. At five places, however, Dos-Sor, Iskene, Makat, Karaton, and Karatchungul, a certain number of zaiavkas were reserved by the original concessionaires, their plots and those of the Ural-Caspian Corporation alternating like the black and white squares on a chessboard. The new owners of the concession had to get to work and choose their zaiavkas before the end of 1912, and their surveyors and geologists had a busy time, and by the end of the period more than 11,000 zaiavkas had been selected.

Other companies subsequently acquiring territory within the area of the original concession were the Emba, Messrs. Nobels, the Emba-Caspian, the Kolchida of Baku, and others.

Up till now Dos-Sor has been the main centre of development. It was brought into prominence by well No. 3, of the Ural-Caspian Co., which on May 13th, 1911, from a depth of 732 ft., spouted with great violence; after one and a half days it caught fire and destroyed the derrick, but was finally arrested. It began to flow again in February, 1912, was closed down, and reopened in October, 1912, when in the first twenty-four hours it gave 120,000 poods (1,944 tons), and then settled down to 50,000 poods. Oil from it was received into an ambar (earth reservoir); but this broke down through flooding after heavy rain, and about 300,000 poods were lost. The well was then shut down till proper storage was built. This famous gusher is estimated to have produced in the early part of its history from 1½ to 2 million poods. It has since produced nearly 7 million poods. Last July it was stopped for cleaning and redrilling.

Since the Ural-Caspian No. 3 came in several other fountains have been struck at Dos-Sor by the same company, also by the Emba-Nobel, and more recently by the Emba-Caspian Co., and the production from this centre has steadily increased. It is still the only field from which oil has actually been exported. There are now some fifty-nine wells yielding oil: Ural-Caspian Co., thirty-two; Emba-Nobel, twenty-one; Emba-Caspian, six.

During 1912 Dos-Sor was connected by telegraph with Guriev. At the end of that year it was still a very small place, but a big building programme was then commencing. Pipe-lines were being laid both by the Ural-Caspian Co. and by Messrs. Nobels to the fishing village at Rakusha, at which point the oil is shipped and where refineries have been constructed.

Owing to the activities of the various companies mentioned above, the difference in Dos-Sor as seen late in 1912 and again in 1914 is startling, and it is now quite an important settlement with a population of over 2,000. The accommodation for the staffs and workmen is good and up to date, as are also the schools, religious establishments, sanatoria, and provisions for recreation. The chief difficulty as the place grows is to obtain a sufficient supply of good water. The administration of the different companies has been gradually moving from Guriev to Dos-Sor.

At Makat and Iskene a little drilling has been done since the concession was taken over in 1910, but without any important results. However, it was announced early this year that the Emba-Nobel Co. had a fountain at Makat. Preliminary work or trial drilling has been carried out also at Bli-ule, Bek-Beké, Iman Kara, Satep Aldi, and at other spots.

Drilling by the Canadian-Galician system was employed in the first place by the Ural-Caspian Co., but gradual modifications have been introduced by their engineers to suit the special requirements of the district. The Russian percussion system is also used by other firms. On account of the scarcity of water, oil-engines are largely employed.

The sudden outbreak of war in the summer of 1914 put a great check on the development of the Uralsk and of other oilfields. Capital immediately became scarce. A great deal of prospecting and preliminary work was necessarily stopped, and even the companies who were already well established had great difficulties to overcome. The loss of employees of every grade, difficulties regarding transport, the requisition of automobiles for Government service, all tended to disorganise their industry. All available resources were devoted to continuing the production from existing wells, drilling was confined to wells expected to produce shortly, while trial borings and new developments were to a great extent arrested.

The centres of development already referred to are in the "concession" area, and are being worked by the companies established there. Trial drilling and other exploratory work has been carried out, and in some cases is still proceeding, in spite of the war, by various firms at different places, some of them remote from Guriev and the Caspian Sea. It is impossible to get particulars of all of these; the operations are generally conducted with as little publicity as possible, and at the present time it is hard to get information from Russia. A few of them, however, are referred to here.

At Novo-Bogatinsk, on the Cossack lands, thirty-eight miles west of Guriev, exploration by deep drilling has been started lately by Messrs. Nobels and by the West Ural Co.

The former firm put down a well in 1912, finding some oil and a great deal of gas; this was followed by other trial wells with some success, but the exact results obtained were not made public.

In 1914 the West Ural Company drilled two deep wells by the rotary system. Finally, in August 6th, 1915, Messrs. Nobels struck a gusher, stated to have given an estimated yield of 300,000 poods in twenty-four hours. This is of considerable interest and importance, as the Cossack lands west of Guriev present somewhat of a geological puzzle, and differ a good deal from the Dos-Sor district. It is stated also that a Moscow firm, which has more recently started work in this district, has struck a small gusher.

At Tchernaia Rietchka, near Guriev, where surface indications of petroleum gas were observed some years ago, a little oil was found in some shallow boreholes near the tomb Kara Kis in 1913, and in 1914 Messrs. Nobels were drilling a trial well a little farther west.

At Maten Hoja (or Kuza), some eighty versts east of Kalmikovsk, Messrs. Nobels drilled a 300-ft. hole near a strong seepage of oil and gas in 1913, but got no result. In 1914 another well beginning with 16 in. diameter was started. A report referring to the striking of oil recently would appear to refer to this spot, or at least to this district, judging from the position described, although the name Maten Hoja is not used (this tomb, it may be remarked, is about three miles from the boring site selected last year, which might account for the name not being employed).

In the Novo-Kazanka district, Glininsky, the same firm are stated to have found good oil at small depths in several shallow borings.

At Djusa, just outside the Uralsk Province, in Turgai, a good oil of light specific gravity is said to have been obtained during 1914 at small depth.

At Murtuk, by the Temir River, oil is reported to have been struck.

Drilling was stated to be proceeding in the Karagandy Gorge by Messrs. Nobels, and at Kara Dzhidele by the South Eastern Petroleum Co. These spots are both in the Temir district.

Attention has also been turned of late, east of the Uralsk Province, to the Turgai.

Pipe-lines and Storage.

There are two 6-in. pipe-lines taking oil from Dos-Sor *viâ* Iskene, a distance of 45 miles, to Rakusha, the shipping port, where the refineries are situated. On account of the shallowness of the water, pipe-lines are laid on the sea bed and terminate at platforms six miles out, where the barges can moor. Of the two lines from Dos-Sor, one belongs to the Ural-Caspian Co., and is underground and embedded in cement; the other belongs to Messrs. Nobels, and is exposed. The first-mentioned line was at first provided with one pump, and could only handle 30,000 poods per diem. The addition of a second pump increased its capacity to 52,000 poods.

At Rakusha the Ural-Caspian Co. have tank storage for seven million poods, besides considerable tankage at Dos-Sor.

There is a trifling difference in the price of oil at Rakusha and that at Baku on account of the greater difficulty of shipping at the former place.

Refineries.

At Rakusha refineries have been erected by the Ural-Caspian Oil Co. and the Emba Co. The refining of oil in the district was undertaken in the first place with a view to getting the rebate of 50 per cent. of the excise duty on refined products, granted as one of the privileges of the concession.

When this condition ceases the question of refining oil at Rakusha will have to be considered entirely on its merits, and may possibly be discontinued.

As to the results obtained by refining, we may quote from a report of the Ural-Caspian Co. that in April–October, 1914, when the first trial distillations were made, a quantity of 6,789,122 poods gave—

	Poods.	Per cent.
Gasoline	24,830	0·36
Kerosene	1,607,366	23·66
Residues	5,094,009	74·92
Loss	71,917	1·06

The oil from the first gusher, No. 3 Ural-Caspian Co., was described as of specific gravity 0·861, greenish, and of good quality. The oil from another well, No. 10 of the same company, and coming from the same horizon as No. 3, was lighter, specific gravity 0·85, and, it is stated, could be used very well in lamps. From Karatchungul, oils of specific gravity 0·828, 0·858, and 0·853, and from Karaton of 0·867, have been obtained.

Seven samples of oil from the Guriev district are stated in Redwood and Eastlake's pocket-book to have specific gravities of 0·839, 0·869, 0·876, 0·880, 0·903, 0·904, and 0·908.

Production.

As already stated, up to the present time petroleum has been obtained in commercial quantities at Dos-Sor only.

During 1912 the production, only just beginning, is stated to have amounted to 1,017,000 poods. In 1913 the quantity was about 7,182,000 poods, and by the close of navigation in 1914 (statistics down to October, 1914) another 12,923,000 poods had been produced, making the total amount, from the beginning in 1912 to the close of shipping in 1914, some 21,122,000 poods, or 340,487 tons, of which it was estimated that the different companies produced in the following proportions:—

Ural-Caspian Oil Corporation	60·8 per cent.
Emba (Nobel)	38·0 ,,
Emba-Caspian	1·2 ,,

The above figures do not, of course, take into account the oil lost from the great gusher, estimated at 1½ to 2 million poods.

Comparison with other areas is somewhat premature, as the Uralsk-Emba fields are still in the infancy of their development, but, according to an estimate of the first nine months' production of the current year (1915), Dos-Sor produced some 13 million poods, which is just equal to the production for the same period in 1914 (first nine months) of Holy Island, Maikop, Tcheleken and Fergana combined (the joint production of these four oilfields was somewhat greater for 1915, 16 million poods, largely due to the Maikop gusher).

The production for the same period, January–September, 1915, of Russia was 426 million poods, of which 331 million came from Baku and the Apsheron peninsula. These figures are only approximate.

The rapid increase in production may be seen from the official figures of one company (the Ural-Caspian Oil Corporation). Beginning with the small production of 1912 there was—

In hand in April, 1913 .	1,128,000 poods.
April, 1913–April, 1914 (12 months)	5,658,430 ,,
April, 1914–November, 1914 (7 months)	6,056,868 ,,

while for the last twelve months (November, 1914–November, 1915) the production of this company was 10½ million poods, while their shipments in 1915 were about—

Kerosene	1,390,000 poods.
Crude	1,730,000 ,,
Residuals	7,441,000 ,,

It is estimated by the Ural-Caspian Oil Co. that their thirty-two producing wells, if allowed to yield without restriction (*i.e.*, if questions of transport, storage, labour, etc., did not impose any limits), are capable of producing from 350,000 to 400,000 poods weekly.

Occurrence of Petroleum.

The great plain which occupies all the central and western portions of this country is very barren of geological indications of any kind, the whole surface having been levelled and overlaid by the recent sediments of the Caspian Sea, a few isolated outcrops and the data obtained from pits and boreholes being the only evidences of structure available.

In the low-lying plain which occupies the southern and western parts of the petroliferous area, seepages occur at many points, the oil escaping from the reservoir beds and finding its way up through the Caspian sediments, spreading as it does so often in the neighbourhood of the "sors" or lakes which abound in the plain.

In some places "gas-holes," around which there is often a deposit of sulphur, are met with. Although not necessarily indications of petroleum, they appear generally to be associated with it in this region. Some of these spots are venerated by the Kirghiz, and are surrounded with little sticks with small pieces of cloth, etc., tied to them, the votive offerings of the pious.

The indications which first drew attention to the Dos-Sor, Iskene, Makat area were seepages of liquid oil rising through the sands. At Makat the reservoir beds are brought near the surface, and in shallow pits under a few feet of recent deposits beds with Lower Cretaceous fossils are exposed.

It is, however, in the higher lands to the east that the evidence as to the age of the oil-bearing beds is to be found. In some places they crop out on the sides or at the feet of hills, as at Iman-Kara, Kara-Murat, Alasha-Kazgan. In other places the exposure of the petroliferous strata is due to erosion by rivers.

The beds from which the oil issues, or which have deposits of "kir" (asphalt) at their outcrops, belong to the series of sands and clays already referred to as underlying the chalk. The most valuable data, gained through prolonged study of the district and of the well-records by their resident geologists, are of course the private property of the companies operating in the oilfields, and are not available. We may, however, safely conclude that the reservoir rocks in which the oil is stored under the Caspian sediments belong to the lower part of the Cretaceous (possibly also, in part, to the Jurassic). This, however, does not settle the question of the origin of the oil, the reservoir not being necessarily the bed in which the oil was formed.

The Permian is known to be petroliferous in Kazan, Samara, Simbirsk, Ufa and Orenburg, and may be the source of some if not of all the oil in the Ural-Emba district.

It has already been stated that some rocks generally considered as Permian have also been assigned to Tertiary and Post-Tertiary times. The gypsum of Karatchungul and that west of Guriev have both been the subject of some controversy, and will be briefly discussed here. At Lake Karatchungul, through the sands of the surrounding plain, rises an island of gypsum in which a hollow has been formed by solution of the rock. Under the Caspian sediments Cretaceous rocks are found, and the presumably Permian gypsum appears to rise through a cover of Cretaceous.

The view, however, has been advanced that the gypsum is recent, a deposit of the Caspian Sea, and that the Cretaceous has been brought near the surface in places by folding, the hollows in the Cretaceous being filled by gypsum. This idea appears to have been suggested by the finding of some recent shells in a deep borehole

n the gypsum. Such evidence, however, is not convincing. Shells from the overlying sediments may easily fall into a borehole, or, again, there may have been deep hollows in the gypsum formed by solution before the Caspian Sea covered the area. There exists such a hole to the west of Guriev, described by the inhabitants as a bottomless pit. In any case, it is difficult to conceive of beds of gypsum nearly 1,000 ft. thick being deposited by the Caspian Sea in recent times.

At Inder, near the east bank of the Ural River and about 150 versts north of Guriev, is a salt lake with gypsum cliffs on its northern shore. A broken chain of hills some 200 ft. high, 40 versts long, and 7–10 versts wide, with a general N.W.–S.E. trend, lies to the north of the lake. The north-western extremity of this range reaches the Ural River.

To the north of the lake the gypsum, with a conformably overlying sandstone, strikes N.E. and dips steeply to S.E., being in places turned over. Anticlinal structure is clearly observed in the gypsum.

On the west flank of the anticline a series of Jurassic beds lie unconformably, identified by fossils as Callovian and Portlandian. Following these, to the west are calcareous clays, and finally the white chalk. These beds, unlike the gypsum, have a north-westerly strike and a south-westerly dip. At the west of the range, at a place called Biele Rostosch, the white chalk is overlaid by beds assigned to the Aktchagil (Tertiary) series. The position of the gypsum here, relatively to the other beds, sufficiently indicates its pre-Jurassic age.

The same general strike of the gypsum is also observed to the east of Lake Inder to be N.N.E., with an easterly dip about 25°.

To the west of Guriev, between that town and the Tchernaia Rietchka, or Black River, several low anticlinal ridges of gypsum, yellow sandstone, and mudstone project through the Caspian deposits, striking N.N.E. A small island (Kameni Ostrov, or Stone Island) about 4 versts out in the Caspian Sea, showing the same material and strike, is a prolongation of these folds.

Going towards the tomb Kara Kis, which is on the Black River, 5½ miles west of Guriev, the gypsum is found in boreholes at successively lower levels, and at Kara Kis, where evidences of gas had been previously observed, small quantities of oil were found in 1913 in shallow boreholes above the gypsum. Further west the gypsum is lost sight of, but is found again by drilling at Novo-Bogatinsk, together with great thicknesses of salt.

The view has been advanced that to the west of Guriev the Caspian deposits are underlaid by a considerable thickness of Tertiary beds, and that the gypsum and salt beds here are much younger than those reached by drilling on the oilfields to the east (in the "concession" area). The similarity between the conditions of the gypsum west of Guriev, at Inder, are, however, sufficiently striking, and in the absence of further evidence it seems most reasonable to ascribe the gypsum of Tchernaia Rietchka and of Karatchungul, like that of Inder, to the Permian.

Transport.

All goods for Guriev and for the oilfields are landed at the Preestan or port, eight miles from Guriev. As already stated, the steamers cannot come to the shore, and the goods are either carted in from the tugs, or when the water is high enough (when the wind is not blowing off the shore) barges of light draught can be brought alongside the piers to discharge, and in this way heavy machinery can be got ashore.

Further transport is effected in carts drawn by horses or camels to Guriev, and then across the Ural River to the oilfields. This cartage of machinery, casing, provisions, etc., to the different centres has been a valuable source of employment for both Cossacks and Kirghiz. A number of automobiles are in use in this country now, but the older method of traction, though somewhat slow, is still the most reliable and economical for heavy goods.

Water Supply.

In Guriev each house has in its yard or outbuildings one or more large barrels or tanks for water storage. The water is brought to them by men who make a business of fetching it from the Ural River, into which they drive their water-carts, which consist of large, long barrels laid on their sides with square holes on the top (really on the upper "side") mounted on low carts. The scarcity of water in some parts of the steppe, already referred to, has caused much inconvenience at some of the centres of development, Dos-Sor, Iskene, Makat, etc. Water had to be carted from distant wells to these places—an expensive and inadequate method. The difficulty was to a certain extent overcome by the device of storing snow during the winter in long deep trenches, roofed over with non-conducting materials. Water is drawn from a sump at the end of the trench, and keeps quite cold even during the hottest summer.

The road from Guriev to Iskene, Dos-Sor and Makat is on a very dry part of the steppe, and several small stations have been erected, where water is stored for the use of the companies' employees, horses and camels on the road. The water has, of course, to be carted to these stations. There has been talk for some time of bringing water by pipes from the rivers to the oilfields, and there is no doubt that sooner or later something of the kind will have to be done. At present some automobiles are being used to bring water from the River Sagiz and other sources.

CHILEAN COAL.

By Josiah Harding, M.Inst.C.E.

(Translated by the author from an article on "El Carbon National" in *El Mercurio*, of Santiago, Chile, October 28th, 1915.)

From a series of interviews and articles recently published in the *Mercurio*, I see that this business is at last receiving the attention due to it. It is really very sad that a question of such transcendent importance has not before this been dealt with.

Commissioned by several firms and at different periods, I have had occasion to study some of the Chilean coal-fields, as also the best way of using the coal; so that I am in a position to contribute something to the study of this problem, which is of national interest.

Indications of coal are found in many parts of Chile, from Valparaiso to the Magellan Straits, but the fields which up to the present have shown great importance are those of the provinces of Concepcion and Arauco, and those of Valdivia and Magellan.

The most important Chilean coal-field is undoubtedly that of Arauco, which extends along the western foot of the Nahuelbuta range from Coronel (lat. 37° S.) to beyond Cañete (lat. 38° S.). The beds acquire their greatest thickness, purity, and uniformity in Cuyinco.

There is another coal-field opposite this along the coast from Huena Piden to Lebu, and between these two fields lies a great bed of fire-clay, of which I had a sample examined in England, and which proved quite suitable for pottery. This whole district will soon be crossed by the railways from Lebu to Sauces, and from Curanilahue to Los Alamos.

Regarding quality, I believe this coal may be classed as superior to that of Australia, and for many purposes better than some English coals. Although this coal can be used in ordinary furnaces and boilers, there are certain alterations which it is desirable to make where the permanent use of Chilean coal is contemplated.

As the result of experiments in locomotives, I was able to burn it without making *any* black smoke. To obtain this end it is necessary to admit part of the air required for combustion above the fire-bars and beneath a fire-brick arch. This is usually done through the fire-door with a baffle plate, but it is better to make two small openings in the front end of the fire-box immediately under the brick arch provided with doors by a lever from the foot-plate to adjust the air supply. The fire-bars should also be placed closer than for English coal, and a large combustion or flame space is also advisable. These arrangements are not indispensable, but conduce to economy and elimination of smoke.

Owing to the small quantity of tar contained, this coal lends itself admirably for making Mond gas, whether for boilers, furnaces, or gas-engines, in which service it will show a considerable economy over a steam-engine.

The coal obtained from the fields referred to could be shipped either at Coronel or Lebu, the latter being the most suitable port, although it would be necessary to expend a considerable sum to make Lebu available at all seasons. The companies who propose to exploit these coal-fields would do well to provide sufficient capital to include the cost of some colliers, as is done by the Lota and Coronel Company.

Regarding protection to the coal industry by means of an import duty on foreign coal, the conditions of the Chilean coast enable a duty to be levelled on all coal imported, from Caldera southward, leaving the northern ports free, and so avoiding an extra tax on the nitrate industry.

The fact that these great coal-fields have remained for so many years unworked would seem to indicate that the business requires State aid or protection in some way during the first few years. Coal-mining requires the inversion of large capital, with no prospect of returns during a few years, although afterwards the dividends are certain to be very good.

It is certainly worth while for the State to make some sacrifice, so that all or nearly all the coal now imported be replaced by a national product. Further, the quantity of coal that might be produced in the province of Arauco is so great that there would certainly be a surplus, which might be exported to the Argentine Republic. There is, in fact, a proposal to extend the Lebu-Sauces Railway across the Andes by the Pass of Lonquimay, placing these coal-fields in direct communication with the Argentine railways and with the port of Bahia Blanca.

TRADING WITH THE ENEMY.

The following communication has been issued by the Press Bureau :—

The Foreign Trade Department of the Foreign Office has been set up by the Foreign Office as a new Department in order to carry out the policy embodied in the Trading with the Enemy (Extension of Powers) Act, 1915. This Act gives power to prohibit trade by any person, firm, or company in the United Kingdom with any enemy persons or association established in neutral countries.

As the Foreign Trade Department will be concerned with preventing trade by British firms and companies with the enemy in neutral countries, it has been decided to merge with it the Trading with the Enemy Department of the Home Office, which has had the duty of enforcing the measures already taken to prevent trading with the enemy, and the staff of which will continue to perform the same duties as members of the new Department, in addition to taking part in the administration of the new Act.

Questions of contraband or the hindrance of oversea trade between neutrals and the enemy and the licensing of exports from this country,

and all questions of trading with the enemy other than those described above, will continue to be dealt with by the Government Departments which have hitherto been charged with these questions.

In order to secure the full benefit for British interests of the policy of the Department, the advice and assistance of business men will be invited through the Chambers of Commerce and other trade organisations. It is recognised that the success of this policy will depend upon the active co-operation of the business community. It is hoped, therefore, that business men will be willing to aid the Department, and also that they will not hesitate to consult it in any matter in which it can be of assistance to them.

Mr. L. Worthington Evans, M.P., has undertaken the direction of the new Department, with the title of Controller of the Foreign Trade Department of the Foreign Office. Offices have been obtained at Lancaster House, The Mall, S.W. (above the London Museum), which were opened on January 5th. All communications (including those relating to matters previously dealt with by the Trading with the Enemy Department of the Home Office) should be addressed to: The Controller of the Foreign Trade Department, Lancaster House, The Mall, London, S.W.

ARTS AND CRAFTS.

The Children's Room at the Victoria and Albert Museum.—It seems eminently fitting that the Victoria and Albert Museum should make special provision during war-time holidays for children, many of whom are rather at a loss for occupation this Christmas, and should try to interest them in the mass of interesting objects which the nation possesses. Certainly the small room given up to the youngsters at present cannot be said to suffer from lack of visitors, and they seem to enjoy themselves very thoroughly. On the other hand, when one turns to the objects on view, and considers the size of the children who are filling the room, one cannot but ask the question, "Why in the world is an exhibition of this type held at South Kensington?" It might with equal propriety and profit be held at Bethnal Green, or really at any of the local play centres. Undoubtedly the Victoria and Albert Museum does not attract as many visitors as it ought to do in virtue of the treasures which it contains and the attractive manner in which many of them are now displayed. There are many young people growing up who ought to know and use the galleries who are hardly conscious that they exist, and who, once they came to know them, would not only find them useful but would learn to derive much happiness from them. Still it must be remembered that the Victoria and Albert Museum is not, probably cannot be, a museum which makes so universal an appeal as a picture gallery, or such institutions as the Natural History Museum or the London Museum. In the first place, it takes rather more education to begin to appreciate what it contains. In the second, the main object of the collection is not a popular one. The museum was originally founded as a museum of industrial art. When the new building was opened the scheme of rearrangement was based in the main on the principle that the problem to be solved was the housing of the national treasures in such a way as would best fit them to serve this initial purpose. The historical interest was not altogether ignored, but its claims were rightly regarded as subservient to those of art and craftsmanship. Now an exhibition of this type does not and cannot make an appeal to the ordinary child of, say, eight or nine years of age. It is useless to encourage him by the provision of a solitary room filled largely with costume dolls and glorified dolls' houses and a few military objects. Directly he is outside its door he is lost in what is to him a wilderness, and if he is a child who has wandered in by himself and not a well-to-do boy brought by fond and anxious parents or friends, he tries to distract himself by meddling with the labels, playing with the handles of the furniture, and generally making himself a nuisance—and small blame to him. It is, of course, always difficult to see how a first experiment will work out, and all honour is due to the originators of the present scheme for having made a step in the right direction. For all that, it is to be hoped that, in the years to come, exhibitions intended for quite small children will be held elsewhere, and that a larger room may be set apart at South Kensington which will be intended primarily for young people of between twelve and fifteen who would be led on by what they see there to explore for themselves, with some chance of profit, the rest of the exhibition galleries. There are plenty of boys in the upper standards of the elementary schools who would thoroughly enjoy seeing, under a little guidance, just how a Japanese stencil is cut and what can be done with it, or how different people have treated hinges, or chair legs, or whatever it may be. There are still more boys and girls in our trade and technical schools who would learn more than can be told from an exhibition planned to meet their special needs. If they once came to look upon the Victoria and Albert Museum as the place where they really found what they wanted at that age, there would be a very good chance of their making use of it to good purpose in later life.

Art and Trade Schools and the War.—We are living in troublous times, and it is only natural that art should suffer from them rather more

than certain other branches of activity. Fifteen months ago it was mainly the artists and art workers who were feeling the pinch; to-day the changed circumstances are having an influence on the schools as well. A few of them are on the point of closing, many more are finding themselves hampered by the reduction of grants, whether from the local or the central authority, whilst the older male students either have enlisted or are occupied in some employment connected with the war. In the trade and technical schools the conditions are somewhat different, but even here the war has not been without its results—results which, though some of them are right and necessary, do not always seem to be either. For instance, whilst it seems perfectly legitimate for the local authorities to try to reduce their expenses and their staffs, one cannot help wondering on what principle, if any, the changes are carried out. In some departments, of course, the work is considerably less than it was, in others this seems the moment for pushing forward rather than for holding back. The working of all the organisations which deal with the higher education of boys is necessarily thrown out of gear, but this is not, or at any rate should not be, the case as regards the girls. It is surely more important now than ever it was to train girls thoroughly and efficiently to undertake skilled industrial work. Girls of fourteen to eighteen cannot be employed as nurses; it is undesirable to turn them into munition workers for the period of the war and then leave them to find what unskilled work they can for the rest of their lives. The more girls who can be trained now to take their places later on as intelligent skilled workwomen the better both for themselves and for the country at large. The strides which have been made in the general efficiency of the women's trade schools within the last few years was very well shown in the informal exhibition held at the Shoreditch school just before Christmas. It seemed, from the exhibits there, as though two of the main problems in education of this kind were on their way to being solved—the correlation of the artistic and technical side of the training, and the relation of the more literary education to them both. The work done in the "art room" was carried out on a very carefully and wisely-considered plan which led the students by gentle stages to grasp the main principles which lie at the root of elementary design, and the connection between the drawing and the practical work in embroidery, upholstery, etc., was wonderfully close. It was quite evident that there was no keeping the work in water-tight compartments, the two sides fitted into one another almost automatically. Again, the plan of teaching history to girls who are to be dressmakers, upholstresses and embroideresses in such a way that it not only lives to them, but is connected with their work, is one which bids fair to be productive of excellent results. Not only did the girls' books show the reasonableness of the scheme, but the attitude of the students (some of whom had been responsible for the simple copies of mediæval costume which were on view) showed how intelligent was the interest which this plan of study had awakened in them. An attempt to correlate the studies which, though necessarily rather different in scope, is similar in its aim, is bearing very good fruit at the School of Art Woodcarving, and it is to be hoped that in technical schools both for boys and girls this method of work will be increasingly adopted.

Christmas Cards.—This season has been hailed in some quarters as of importance as marking the first Christmas of all-British Christmas cards. There is a certain amount of obvious truth in the remark, of course, but as a matter of fact there were not a great number of German cards about last year, and there seems very little indication that the volume of British cards this year has been greater than usual. If it were not dangerous for anyone outside the trade to hazard a guess, one would be inclined to say it was probably less. Many people felt that their hearts were rather out of tune with the sending of "Merry Christmas" or even a more subdued greeting, and others were bent on economising. Such cards as there were, however, were on the whole very promising. They included, of course, a good many which had no pretensions to artistic value, but amongst those which aimed rather higher the standard of achievement was good. Some of the autograph cards with illuminated borders were designed in the right spirit of the olden days and introduced the Allied flags, the Gallic cock, the Russian eagle and other symbols of the Allies with varying success, it is true, but on the whole with a good deal of cleverness. There were a good many reproductions from the Old Masters, and one series in monochrome was very satisfactory. The more expensive and pretentious coloured pictures (though much better than such things would have been some years ago) were rather heavier in tint than they should have been, and a little inclined to be dingy rather than mellow. One inexpensive little card (brought out by a very well-known house) of the Botticelli at Milan was admirable in colour, and recalled the earlier coloured postcards of the same picture, which were a triumph of cheap colour work.

OBITUARY.

Thomas Robson Miller.—Mr. Thomas Robson Miller, who was elected a member of the Royal Society of Arts in 1889, died at his residence in Streatham on the 9th inst. in his eightieth year.

Mr. Miller was born at Heworth, Durham, in 1836. When twenty years old he entered the office of the North of England Steamship Insurance Club; a few years later he was appointed secretary of the club, and subsequently was also secretary of the North of England Steamship Protection Association. In 1886 he proceeded to London and became manager of the United Kingdom Mutual Steamship Insurance Association.

He took an important part in the establishment of the Shipping Federation in 1900, and was elected chairman of the Legal and Indemnity Committee, which office he vacated on being appointed chairman of the Finance Committee. He was for many years chairman of the Bureau Veritas, and of the Association of Average Adjusters for 1909. He was also for some time a member of the Council of the Chamber of Shipping and of its Parliamentary Committee.

GENERAL NOTES.

Opening the Yangtze Gorges. From a recent report by the United States Commercial Attaché in Pekin, it appears that the directors of a steamship company have petitioned the Chinese Government for a grant from the Szechwan Provincial Government to open certain gorges in the upper courses of the Yangtze River. The petitioners informed the Government that through their efforts some narrow and dangerous gorges in the Upper Yangtze have been opened, proving a boon to navigation in that part of the river; there still remain, however, four gorges to be opened. The estimated cost of the work is £40,000, of which the Governor of Szechwan has consented to raise £12,000. The petitioners requested that the other £28,000 be temporarily appropriated from the public funds of the Szechwan Provincial Government, to be refunded by the proceeds from a toll to be levied upon vessels passing that part of the river after the gorges are opened. The Ministry of the Interior has approved the plan of the petitioners' enterprise, but has decided that the question relating to the appropriation of funds for this work should be left in abeyance until the Ministry has obtained the views of the Governor of Szechwan.

Newspapers in Germany.—According to the *Paper Maker*, before the war there were about 6,000 newspapers and periodicals in Germany, and about 3,500 in Austria. Of these since the war some 1,100 of the German and 900 of the Austrian have ceased publication, while nearly 500 German newspapers have been compelled to raise their price owing to the dearness of paper, the generally increased cost of production, and the decrease in revenue from advertisements. Since the war nearly 7,000 books and pamphlets have appeared in Germany which come within the category of war literature, almost all being connected with propaganda.

The Wheat Crop in France, 1915.—According to the returns issued by the Minister of Agriculture, the wheat harvest in France for 1915 is estimated at 84,360,000 hectolitres (28,998,750 quarters), equivalent to 64,720,000 quintals (6,370,079 English tons). This shows an average yield of 14·82 hectolitres per hectare (16½ bushels per acre), which is below that of former years.

Output of Coal in the United Kingdom in 1914.—The total output of coal in the United Kingdom for the year 1914, according to the annual report of the Chief Inspector of Mines, amounted to 265,664,393 tons, and the value, £132,596,853, showing a decrease in the output of 21,766,080 tons, and in the value of £12,938,816, as compared with the figures for 1913. The average price of coal was 9*s.* 11·79*d.* per ton in 1914, as against 10*s.* 1·52*d.* in 1913. The quantity of coal exported (exclusive of coke and manufactured fuel and of coal shipped for the use of steamers engaged in foreign trade) was 59,039,880 tons. Of this, France received over 12¼ million tons, Italy over 8½ million, tons, Germany over 5¼ million tons, Sweden over 4¼ million tons, Russia over 3 million tons, Denmark over 3 million tons, Spain nearly 3 million tons, the Argentine over 2⅝ million tons, Egypt over 2½ million tons, Norway nearly 2½ million tons, and the Netherlands nearly 1⅞ million tons. The amount of coal remaining for home consumption was 184,670,503 tons, or 3·977 tons per head of the population. 36,289,010 tons were used in the manufacture of coke and briquettes, and 18,381,106 tons in the blast furnaces for the manufacture of pig iron, as against 39,560,489 tons and 21,223,607 tons respectively in 1913.

Direct Railway between Turin and Nice.—Since the outbreak of the war, the works on the French portion of the Nice and Cuneo Railway, with the exception of the piercing of the two principal tunnels—the Braus, 5,950 metres (3 miles 1,225 yards), and that of Mont Grazian, 3,880 metres (2 miles 722 yards) in length—have been at a standstill. At the former of these, the Braus, a junction of the two headings, driven from each side, was effected at the end of September. The boring machinery at both tunnels is driven by electricity.* It is stated, on good authority, that the works of this railway will shortly be resumed on the French side. In Italy the line is now open for traffic to within a mile of the frontier line at San Dalmazzo, the distance from Turin being 147 kilometres (91 miles). A branch, which will join the main line at Breil, 26 kilometres (16 miles) in length from Ventimiglia, most of which is in Italian territory, has already been opened to the public for about half the distance to the village of Airole.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

JANUARY 19. — LAWRENCE CHUBB, "The Common Lands of London: the Story of their Preservation." LORD FARRER will preside.

JANUARY 26.—J. ARTHUR HUTTON, Chairman of the British Cotton Growing Association, "The Effect of the War on Cotton Growing in the British Empire." SIR DANIEL MORRIS, K.C.M.G., D.C.L., D.Sc., will preside.

FEBRUARY 2. — THE HON. LADY PARSONS, "Women's Work during and after the War."

FEBRUARY 9.—PROFESSOR J. A. FLEMING, M.A., D.Sc., F.R.S., "The Organisation of Scientific Research." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, will preside.

FEBRUARY 16. — S. CHARLES PHILLIPS, M.S.C.I., "Paper Supplies as affected by the War."

FEBRUARY 23.—MISS H. B. HANSON, M.D., B.S., D.P.H., "Serbia as seen by a Red Cross Worker."

MARCH 1.—CHARLES DELCHEVALERIE, "Belgian Literature."

MARCH 8.—CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Optical Appliances in Warfare."

INDIAN SECTION.

FEBRUARY 17.—C. A. KINCAID, C.V.O., Indian Civil Service (author of "Deccan Nursery Tales," "The Indian Heroes," "The Tale of a Tulsi Plant," etc.), "The Saints of Pandharpur." LIEUT.-COLONEL SIR DAVID W. K. BARR, K.C.S.I., will preside.

MARCH 16.—PROFESSOR WYNDHAM R. DUNSTAN, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India."

Dates to be hereafter announced:—

R. W. SETON-WATSON, D.Litt., "The Balkan Problem."

REV. P. H. DITCHFIELD, "The England of Shakespeare."

W. A. CRAIGIE, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

VICTOR HORTA, Directeur de l'Académie Royale des Beaux-Arts de la Ville de Bruxelles, "Belgian Architecture."

PROFESSOR T. G. MASARYK, "The Slavonic Peoples."

G. P. BAKER, "Hindu Hand-painted Calicoes of the Seventeenth and Eighteenth Centuries, and their Influence on the Tinctorial Arts of Europe."

EDWARD PERCY STEBBING, F.L.S., F.R.G.S., Head of the Department of Forestry, University of Edinburgh, "Forestry and the War."

SIR DANIEL MORRIS, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland."

JAMES MACKENNA, M.A., I.C.S. (Deputy Commissioner, Myaungmyn, Burma, and designated Agricultural Adviser to the Government of India), "Scientific Agriculture in India."

INDIAN SECTION.

Thursday afternoons at 4.30 p.m.:—

April 6, May 18.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

February 1, March 7, May 2.

CANTOR LECTURES.

Monday afternoons at 4.30 p.m.:—

J. ERSKINE-MURRAY, D.Sc., F.R.S.E., M.I.E.E., "Vibrations, Waves, and Resonance." Four Lectures.

May 1, 8, 15, 22.

FOTHERGILL LECTURES.

Monday afternoons, at 4.30 p.m.:—

REV. DR. HERBERT WEST, D.D., A.R.I.B.A. (author of "Gothic Architecture in England and France"), "National and Historic Buildings in the War Zone: their Beauty and their Ruin." Three Lectures.

Syllabus.

LECTURE I.—FEBRUARY 7.—*Belgian Architecture and History.* Belgium a land of cities—What makes a city (Gen. xi. 4)—Tower—Church—Communal Hall—Belgian civil architecture, commercial—Cloth Halls before Town Halls—Churches borrowed, but splendid furniture given by Trade Guilds. Ypres typical — Tournai. Rhenish. Source of Noyon—Soissons. St. Remi—French efforts to annex Flanders—The Matins of Bruges—Battle of the Spurs. Courtrai—Rivalry of Ghent and Bruges—Edward III. and J. van Artevelde—Sluys—Coucy. Pierrefonds—Mediæval sieges—Philip van Artevelde, Roosebek. Suzerainty of Burgundy—Charles the Rash and Louis XI. Dinant—Sack of Liége. Mary of Burgundy.

Arras—Lierre. Charles V. and Philip II. Egmont and Horn—Louvain—Malines—Antwerp—Louis XIV. and William III. Namur. Bombardment of Brussels.

LECTURE II.—FEBRUARY 14.—*Gothic Architecture, French and English.* The French Cathedral, a Great Hall, the centre of the city's life. The English Cathedral a Monastic Missionary settlement, independent of the city. The problem of Mediæval Architecture, to reproduce Roman vaulting—Solved by permanent stone centrings (diagonal ribs) under the intersections of a groined vault (Vezelay, Durham, St. Denis, Sens). Buttresses necessary (Chartres, Amiens, Beauvais). The walls become screens of glass. Inside—Columns replaced by vaulting ribs running down to the ground (Notre Dame—N. D. de l'Épine Abbeville). Contrast of French and English plans (Notre Dame and Salisbury). In the English Cathedral, horizontal, not vertical perspective sought. Beauty of clustered columns. Purbeck causes deep mouldings. Multiplication of vaulting ribs. Lierne and fan vaulting—Flamboyant and perpendicular—English and French façades—The French Cathedral is the expression of the National ideal; the English, of the National history.

LECTURE III.—FEBRUARY 21.—*French Mediæval Sculpture.* Christian art that of a new-born society rising amidst a dying civilisation—Provençal sculpture, Arles, etc., decadent—Burgundian, full of life and imagination; but Classical influence traceable all through (Vezelay, Autun, Auxerre)—XIIth Century (Avallon, Bourges, N. and S. doors, Chartres, W. front). Elongation of statues, architectural not ignorant—Individual types, elaborate detail. The sculpture scheme of a XIIIth Century cathedral (Laon, Notre Dame, Amiens, Reims). The Judgment door (Autun, Notre Dame, Amiens, Rampillon, Reims, St. Maclou)—The Virgin's door—Local Saints and legends (St. John Baptist, Rouen; St. Stephen, St. Théophile, Paris; St. Thomas, Semur; St. Nicaise, Reims)—The Arts, Virtues and Vices—The Months and Daily Life (Paris, Amiens, Rouen)—Statuary (St. Stephen, Sens—The Virgin, Paris—Chartres, N. and S. porches)—Reims, W. portals—Figures of Christ (Chartres, Amiens, Reims, Troyes, Solesmes).

The lectures will be illustrated by lantern-slides.

EDWARD A. REEVES, F.R.A.S., Map Curator, Royal Geographical Society, "Surveying." Three Lectures.

March 27, April 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 17...Victoria Institute, the Central Hall, Westminster, S.W., 4.30 p.m. Mr. E. J. Sewell, "The Principles Governing Bible Translation."

TUESDAY, JANUARY 18...Statistical Society, 9, Adelphi-terrace, W.C., 5.15 p.m. Mr. T. T. S. de Jastrzebski, "The Register of Belgian Refugees."

Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. H. Barringer, "Oil Storage."

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. S. Sherrington, "The Physiology of Anger and Fear." (Lecture I.)

Photographic Society, 35, Russell-square, W.C., 8 p.m. Mr. F. M. Duncan, "The Application of Photography to Biological Research."

WEDNESDAY, JANUARY 19...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. L. W. Chubb, "The Common Lands of London: the Story of their Preservation."

Biblical Archæology, Society of, 37, Great Russell-street, W.C., 4.30 p.m. Professor A. H. Sayce, "The Land of Nod."

Meteorological Society, at the Surveyors' Institution, Great George-street, S.W., 7.30 p.m. Major H. G. Lyons, "Winter Climate of the Eastern Mediterranean."

Geological Society, Burlington House, W., 8 p.m.

Entomological Society, 11, Chandos-street, W., 8 p.m. Annual Meeting.

Literature, Royal Society of, 20, Hanover-square, W., 5.15 p.m. Professor Sir Henry Newbolt, "Georgian Poetry, 1912-1914."

University of London, King's College, W.C., 5.15 p.m. Dr. R. M. Burrows, "The War and the Near East."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 5.30 p.m.

THURSDAY, JANUARY 20...Geographical Society, Kensington-gore, 5 p.m. Mr. C. B. Fawcett, "The Middle Tees and its Tributaries."

Linnean Society, Burlington House, W., 5 p.m. 1. Mr. M. Christy, "On the Definition of 'Right' and 'Left' in relation to coiled, rolled, revolving, and similar objects: a Problem in Scientific Terminology." 2. Mr. H. W. Monckton, "Some Aspects of the Bagshot Sands Flora." 3. Mr. B. B. Woodward, "Colour-photographs of Mollusca."

Chemical Society, Burlington House, W., 8 p.m. 1. Mr. A. G. Perkin, "The colouring matter of cotton flowers." (Part III.) 2. Mr. A. H. Salway, "Studies on the oxidation of unsaturated fatty oils and unsaturated fatty acids. Part I.—The formation of acrolein by the oxidation of linseed oil and linolenic acid." 3. Messrs. S. G. Sastry and B. Ghosh, "Synthesis of keto-indo-pyranols." 4. Messrs. A. Marshall and G. Peace, "The vapour pressure of glyceryl trinitrate (nitroglycerine)."

Royal Institution, Albemarle-street, W., 3 p.m. Professor W. A. Bone, "The Utilisation of Energy from Coal: the Chemistry and Economics of Coal, and its By-Products." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m.

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Mr. H. H. Harrison, "The Principles of Modern Printing Telegraphy."

Historical Society, 22, Russell-square, W.C., 5 p.m. Mr. E. Lipson, "The Sources Available for the Study of Mediæval Economic History."

Numismatic Society, 22, Albemarle-street, W., 6 p.m.

FRIDAY, JANUARY 21...Royal Institution, Albemarle-street, W., 5.30 p.m. Professor Sir James Dewar, "Problems in Capillarity."

Mechanical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. Captain T. B. Morley, "The Flow of Air through Nozzles."

SATURDAY, JANUARY 22...Royal Institution, Albemarle-street, W., 3 p.m. Mr. C. J. Holmes, "Raphael and Michaelangelo." (Lecture I.)

Journal of the Royal Society of Arts.

No. 3,296. **VOL. LXIV.**

FRIDAY, JANUARY 21, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

Wednesday, January 26th, 4.30 p.m. (Ordinary Meeting.) J. Arthur Hutton, Chairman of the British Cotton-Growing Association, "The Effect of the War on Cotton-Growing in the British Empire." Sir Daniel Morris, K.C.M.G., D.C.L., D.Sc., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

NORTH LONDON EXHIBITION TRUST.

In 1865 the Committee of the North London Working-classes and Industrial Exhibition (1864) presented to the Society of Arts a sum of £157, the balance of the surplus from that Exhibition, with a view to the annual award of prizes for the best specimens of skilled workmanship exhibited at the Art Workmanship Competitions of the Society of Arts. The Art Workmanship Competitions were discontinued after 1870, but since that date various prizes have been awarded under this Trust. Prizes were offered to the students of the Artistic Crafts Department of the Northampton Institute, Clerkenwell, in 1903, and have been continued annually to the present time. These have been awarded, for the present year, as follows:—

Senior Section.—Prize of £1 10*s*. and a Certificate to Emily May Bowler, for a hand-wrought Embroidery Cushion Cover.

Junior Section.—First Prize of £2 and a Certificate to Andrea Vecchione, for an Inlaid Mahogany Bureau.

Second Prizes of 15*s*. each and Certificates to Louis Chambers, for a set of Steel Dies and Impressions; and to William Lonsdale Collis, for a hand-wrought Ciborium and Silversmith's Drawings.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s*. 6*d*. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, January 13th, 1916; Dr. Dugald Clerk, F.R.S., Chairman of the Council, in the chair.

The paper read was—

THE ROMANCE OF INDIAN SURVEYS.

By Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc.

There would not appear to be much room for romance in the prosaic details of a highly technical profession dealing with mathematical deductions and land measurements. Nor does the actual process of bringing into action an assortment of admirably constructed instruments for the purpose of astronomical or terrestrial observations, and deducing therefrom by intricate calculations the shape of the earth and the exact space thereon which is occupied by any special part of it, lead to much romance.

It is not, therefore, with the contents of those elaborate volumes on the progress of the great triangulation of India, which, while they are records for all time of a magnificent work and a great success, are much too technical for light and popular reading, that we have to do to-day, so much as the early beginnings of surveys in the East—the first dawn of those adventurous excursions into the regions of scientific observation—rendered absolutely necessary by our growing Eastern expansion and the further necessity of defining its limits. There is another

aspect of Indian surveys, too, which is well worth a better record than it has yet received. Along with the solid and steady progress of a great scheme for the accurate mapping of the peninsula of India, and the attainment of a full knowledge of its vast resources and possibilities, there has ever been on the fringe of this internal work a tide of adventure, ebbing and flowing with the rise and fall of political interest in what lies beyond India, which has led to the ingathering of an enormous amount of geographical information—all bearing more or less on India and its destinies—and has resulted in a record of geographical enterprise unsurpassed by any such record in the world. Neither Spain, Portugal, nor Holland, the three great geographical nations of the past, can claim an equal position as peaceful world conquerors in the interests of science.

Now, I am very well aware that when we touch on the subject-matter of travellers' tales, we may find ourselves more deeply involved in the regions of romance than would be quite seemly if taken in connection with so dignified and important an institution as the Survey of India, but I feel sure that you will appreciate the fact that there are two widely different aspects of romance, and most of you will have learnt from experience that the romance of the truth often exceeds in interest that other romance which is born of the wild dreams of fancy. Sir Clements Markham, in his admirable *résumé* of Indian surveys,* has very justly observed that before you can survey a country you must first get there; and it was the getting there that started a whole series of maritime adventures, all of which added something to our preliminary geographical knowledge of the road to India, which commenced in the reign of Elizabeth and lasted until the more prosaic, scientific and certain methods of the Indian Marine service.

It was Captain Keeling who first visited Surat in 1607, and practically opened up the way to India, and it was Hawkins, who sailed with him as his second in command, who made that ever-memorable journey to the Court of the Great Mogul to enlist his favour and his sympathies for the English in their first commercial venture on the western coast of India. It was one of the most romantic episodes of the early exploitation of India, and the "plotts," or charts, which were gathered from the observations of Keeling, and of other adventurers who speedily followed in his tracks, resulted in the "Rules for Navigation," published by John Davis of Limehouse. Hakluyt, Archdeacon of Westminster, was the map-maker of this period. He worked on practical methods by collecting information from certain "noted seamen of Wapping." His researches and his invaluable contributions to the early geography of the East have only lately been duly recognised by a suitable memorial set up in Westminster Abbey; but we owe the Hakluyt Society to his memory, which, under the leadership of Sir Clements Markham, has for many years been giving to the public many of the most deeply interesting of travellers' tales of the past, which would otherwise have been lost or forgotten. About the time of his death, in 1616, the East India Company woke up to the value of their literary and geographical possessions, and Hakluyt's successor, the Rev. Sam Purchas, took official charge of the journals of East Indian voyages. His quaint and amusing style has rendered "Purchas his Pilgrimes" a rival in popularity to the "Pilgrim's Progress"; but whilst the latter is the finest allegory that ever was written, it can and must be conceded to Purchas that he is only occasionally apocryphal.

It is a matter for bitter regret to antiquarians that the gradual collection of the logs and journals of many ancient mariners finally outgrew the means for storing them in the East India Company's office. Many were irretrievably lost, and when the India Office came in for the heritage of the old Company's records in 1860, tons of literary material were turned out; and not only journals, but some of the most interesting of contemporary maps and charts have been missing ever since.

It was not until Rennell's days, in the latter half of the eighteenth century, that any attempt was made to produce a map of Hindustan from land surveys; but meanwhile the very necessary process of charting the coasts proceeded apace, and quite a number of useful young seamen made their names famous by their adventurous methods and successful work. Amongst them Wedgborough and Topping were most conspicuous. Topping became Chief Surveyor in Madras in 1794, and it would be exceedingly interesting to know of what his office and instrumental equipment consisted.

In 1800 the first efforts were made to chart the African coast of the Red Sea. Lord Valencia was the moving spirit in the expeditions (three of them) that were fitted out in India for the purpose, and he has left his name at Annesley

* I must acknowledge my indebtedness to this useful work for much of the information recorded in this paper.

Bay, the harbour from which the Abyssinian Expedition under Lord Napier started some seventy years later. A naval officer, Crawfurd, was sent up to the Abyssinian highlands to interview the Negus, and he left some geographical record of his expedition behind him; but, following his tracks during that memorable expedition in 1868, we found that he was forty miles wrong in his value for the latitude of Antalo. This must not be accepted as any criterion of the general usefulness of the geographical surveys of our predecessors in the last century, for I have long ago come to the conclusion that for keen continued power of observation and persistent attention to detail there were a good many of them that could give points to modern explorers. It was the instruments, not the men, which failed.

Between 1820 and 1830 the first surveys of the Persian Gulf were made. The naval headquarters was Bassidor, on the island of Kishm, one of the hottest naval bases in the world, and the duties of the Indian Navy were remarkably comprehensive. Surveying seems to have been carried on in the intervals of slave-trade suppression, pirate hunting, commerce extension, visiting chiefs with the object of maintaining the political *status quo*, and generally establishing British supremacy in the Gulf. Stories of wild adventure in the Persian Gulf have survived till this day. Not less remarkable was the venturesome survey of Mesopotamia. It would not be too much to say that never, since those first expeditions to the land of the Tigris and Euphrates, have conditions for continuous map-making been possible. Considering the importance of the geographical position of Mesopotamia, its wealth of historical association and its extraordinary capabilities, and the difficulties and dangers encountered during the twenty-six years of surveying which were carried on almost without interruption by officers of the Indian Service, this extraordinary work of map-making may well be regarded as an imperishable record for the old Indian Navy.

In 1837 Captain Lynch, who was second in command to Colonel Chesney during the original expedition which was to decide the future of railway communication with India, traversed the whole course of the Tigris from its source in Armenia to Bagdad. He then connected Nineveh, Bagdad, Babylon and Ctesiphon by triangulation. When he had done with the Tigris he set to work on the Euphrates, connecting the head of that river with the Mediterranean by chronometric measurements, and on his final retirement in 1843 was succeeded by his assistant, Felix Jones. Jones had seen service in the Red Sea Survey and about the coasts of India before joining the staff of Lynch. He boldly made his headquarters at Bagdad in command of the "Nitocris," and, although nearly single-handed and full of other duties than surveying, he carried his explorations into the country of the wild and dangerous tribes of Arabs. In 1844 he was with Rawlinson on the Persian frontier; he explored the ancient Nehrwán Canal system, surveyed the ancient bed of the Tigris, discovered the site of Opis, and exploited the Median wall; in 1852 he made a trigonometrical survey between the Tigris and the Upper Zab, fixing the position of Nineveh; and he completed an extraordinary survey career by making a plan of the city of Bagdad on a large scale. His work as a cartographer in actual mapping was excellent, but his Babylonian sheets were lost in the India Office. At the present time it is interesting to know our authority for the original mapping of Mesopotamia, which has, of course, been largely supplemented and extended since, but Felix Jones (who was finally appointed political resident at Bushire) owned the master hand which was responsible for the basis of all we now know.

The name of Lynch is historic in Mesopotamia. It is to the river steam service of Messrs. Lynch and Co. that we owe much of the success of our Mesopotamian Expedition. It is, indeed, only with the assistance of such a river service that our expedition has been possible. In 1832 the naval service, hitherto known as the Bombay Marine Service, became the Indian Navy, and its first admiral, Sir Charles Malcolm, inaugurated a period of activity in exploration and surveying which might almost be called the golden age of survey romance. He founded the Bombay Geographical Society, which at once conjures up a galaxy of famous names such as no geographical society in the world has equalled—Burton, Speke, Grant, Burnes, Wood, Pottinger, Rawlinson were just a few of them. They gathered in their comprehensive group explorers in all the corners of the Eastern world. A re-survey of the Red Sea became an urgent necessity. It was a dangerous and difficult service; not half of that sea was charted, and unknown and unsuspected risks attended every move.

Southern Arabia, East Africa, South-East Arabia afforded such splendid opportunities for pioneer work then as might well make the

mouths of modern geographers water! One of the most marvellous adventures was that of a midshipman—Midshipman Cruttenden—who walked into Arabia on his own responsibility and visited Dafur and Sanaa, whilst he exploited Yemen. It may be that less suspicion attached to the apparently irresponsible movements of explorers in those days. They were certainly received with less hostility, being regarded generally as interesting visitors who could have no ulterior motive in travelling in countries with which they were totally unfamiliar—slightly mad perhaps, but otherwise harmless. Certain it is that no European would dare now to set his foot as a casual tramp in many parts of Southern Arabia (in Hadramaut, for instance) where he could have moved with comparative freedom less than one hundred years ago.

As British rule extended itself gradually from the south and south-east of India across the peninsula to the north-west, it became abundantly clear that a thoroughly sound knowledge of approaches by the sea route should be fully and carefully acquired. Three hundred years B.C. a careful log had been kept of an Indian river expedition which started from about Attok, finally reaching the Persian Gulf. It had been kept by one Nearchos, the admiral of the fleet of the great Alexander; but a river like the Indus and a coast-line like that of Makran will change its contour and its channels in the course of a few years; wind and current will render them hardly recognisable; so the log of Nearchos was clearly out of date. The Arabs, too, when they carried out their successful invasion of the Indus valley by sea as well as by land, in the eighth century A.D., must have furnished themselves with some sort of a useful chart, for the Arabs were most able geographers and navigators, and by far the most scientific sailors of their time. Since then the channels of the Indus, as an open road to India, did not seem to have been fully explored, and a river survey was inaugurated which was full of remarkable incident and surprising results. The survey staff included Alexander Burnes and Lieut. John Wood, both of them names which will ever live in geographical history. Arrived at Attok, Burnes, accompanied by Wood, started on a mission to Kabul. A mission to Kabul in those days meant something very different from the political or military processions of later years Our surveyors and explorers of the last century had little to boast of in the way of picturesque accessories such as great retinues and important escorts. They usually found it advisable to do in Afghanistan as the Afghans do, to wear the dress of the country, and to cultivate its social manners. They talked the language like natives, and they passed for natives in a crowd. This expedition was one of the very earliest feelers out into the wild north-west that was ever projected, and we must remember that it did not start from Peshawar and our present frontier, but had to cross a wild stretch of what might, or might not, prove hostile country before reaching the Indus, should it make a start from India. From Attok, of course, which was well within the territory of the alien Sikh, a good deal of this risk was certainly discounted. At Kabul, Burnes and Wood separated. Burnes struck out to the north-west, across the Hindu Kush, to Afghan Turkistan and the Khanates beyond the Oxus, and he brought back with him a story of travel to Bokhara and Central Asia which created a geographical record and a great public sensation. Wood went north-east also to the Oxus with the express object of finding its source. A Lieut. Wyburd departed on a tour of exploration in Central Asia about the same time, and has never been heard of since. This was in 1835. Wood's adventures on his most astonishing journey to the Oxus are as romantic as the most earnest lover of romance could wish. "Wood's Oxus" is beginning to be rather a rare book; but it is a revelation of the difficulties and dangers of individual travel successfully overcome—difficulties and dangers which doubtless still exist (it would be a perilous journey even now), but which are in these days so largely discounted by our knowing all about them beforehand. It is to be noted that when political discussions were straightened out between Russia and ourselves by the determination of a boundary between Russia and Afghanistan in 1883, it was Wood's Lake (otherwise Lake Victoria) which was adopted as the eastern terminal point of the boundary (though it proved to be by no means terminal), and it was the position given by Burnes of his ferry across the Oxus which was to mark the point where the boundary was to follow the river. This, too, presented its difficulties to actual demarcation. The ferry no longer existed in 1883, and the post-house and buildings which once denoted its position had all been washed into the river. Shortly after there followed the war with Afghanistan. Transfrontier explorations were then discouraged by Government, and they have, in fact, remained discouraged ever since. What has been done in later years has been

done more or less reluctantly under the ægis of the Indian Government, and thus a good deal of the romance which clings to individual initiative and effort was knocked out of trans-frontier surveys. We must, however, remember that very much of our prestige in Asia is due to the insistent recognition of the sacredness of European life both on and beyond our borderland. The death of an Englishman amongst frontier tribespeople has to be instantly accounted for, or vengeance by force of arms must surely follow. In no other way can individual security be assured in a land where the murder of a European is one of the chief qualifications for Paradise on the part of the Mohammedan. Very rightly, therefore, does the Government of India discountenance irresponsible travellers who, employed on no mission of political importance, may involve a frontier expedition and much waste of life and money by their indiscretions in the persecution of their own fads or a search for notoriety. But this is a policy which cuts two ways. Whilst it does not imply any radical hostility to the attainment of geographical knowledge in the abstract, it very much curtails the possibilities of seizing on favourable opportunities for securing such knowledge, and it has had a most disheartening effect on the adventurous spirit of military officers, who would gladly follow the example of the geographical heroes of Bombay records, and arrive at a clear understanding of the wild uplands of the borderland which face them in the distance as they kick their heels in idleness along the Indian frontier. Thus for half a century or more we learnt nothing of the wild border hills fringing the great plateau of Afghanistan or Baluchistan, or of farther Kashmir, or the great Tibetan tableland—nothing, in short, of all that which from the military point of view it was most essential that we should know. When we contrast our inherent fear of "complications" arising from indiscreet exploration with the method actually pursued by Russia during the same period, or which would most certainly have been pursued by Germany had she been in our place, we begin to doubt whether that official policy of excessive caution was not misplaced. Indeed, when we started the last great Afghan war in 1878, we found it very much misplaced, for the loss of life entailed by want of topographical knowledge was sometimes deplorable.

It is time, however, to turn to the inauguration of the land surveys of India as apart from Indian naval records; for although the gradual development of so perfect a system of geodetic measurements and its application to the huge area of the peninsula of Hindustan has little in it during its century of steady progress that savours of romance, yet there are certain points in its history which appeal to the imagination, and of the many personal narratives which are hidden away in the immense series of volumes comprising Indian Survey reports there are some which deserve to be rescued from oblivion by reason of the romantic interest which surrounds them. Conceive the India of a century and a half ago, when roads were scarce and railways were not; when the gradual advance of British occupation by force of arms was just a fight maintained by masses of Indian troops trained on European principles and supported by small but valiant companies of Europeans; the land unredeemed from the vast area of forest which spread absolutely unbroken across the continent from sea to sea, wherein were peoples ranging in their degrees of development from the utter savages, or wild men, of Central India—a people who lived in trees and ate their food raw, splitting it to pieces with their nails—through the black and hairy (but intensely proud) community of the Bhils, and the cairn-erecting Stone Age tribes of Gonds, to the ornate and crafty Bengali, or the magnificent Afghan supporters of the Mogul Court.

It is true that, with the exception of the wild man, who has disappeared within the last fifty years, they are all there now; it is true that there are large spaces still in the Indian peninsula on which no white man ever sets his eyes; that there are most undoubtedly deep-shadowed, dark and remote regions within which the hideous rite of human sacrifice is not unknown (one of the last which was brought to light was performed in order to secure a favourable verdict in the Calcutta High Court); but these interesting relics of the past are rapidly disappearing in front of missionaries and deputy-commissioners; and India, with its hotels and its telephones, its motors and electricity, is becoming unromantic and prosaic. But there was romance in the days when the early researches commenced, and it has not been utterly wiped off the slate even yet.

Our earliest Indian surveyor-general, a man who has left behind him an imperishable name, was Rennell. Rennell served under Clive from 1763 to 1782, when he commenced a geographical career which lasted for fifty years. Rennell produced the first map of Hindustan, which was a compilation from route surveys and observations

taken with more or less care during the military expeditions and campaigns which were then incessant. That first map shows what a mass of information already existed before anything in the shape of exact geodetic triangulation was attempted. The maps from which the compilation was built up were very inaccurate, but the patchwork was pieced together with great skill, and Rennell seems to have considered that no more scientific method was really necessary. Surveying in the peninsula of India in those days was just as much of an adventure as it would be in Western China in our time.

The first really picturesque figure which appears in connection with Indian land surveys is that of Lambton. He was the originator of the Great Indian Survey. He gained a commission as officer of the 33rd Regiment, and he served under General Harris in the war with Tippu. Curiously enough, nothing is known of his origin. He never referred to it himself, but he is believed to have been a Durham man, and to have gained his first experiences in land-surveying in America. He was absolutely self-educated. After the fall of Seringapatam, when Lord Wellesley took measures for exploiting and exploring India, Lambton produced his scheme for the measurement of an arc of the meridian and for carrying triangulation across the peninsula from sea to sea. The measurement of an arc of the earth's surface was in those days of the very highest scientific importance, when we did not know the elements of the shape of the earth. Supported by Lord Wellesley, and approved by the Madras Government, Lambton set to work to collect instruments. A three-foot theodolite (*i.e.*, the diameter of the graduated horizontal plate was 3 ft.) was constructed by Cary. It was the first of its kind. It was the father of all the many theodolites that have followed in its Indian wake, and it fitly has closed its career by honourable retirement in a museum. But the start was inauspicious. It was captured by the French on its way to India, and it was only through the graceful courtesy of the French Governor of the Mauritius that it ever reached its destination.

Great was the difficulty in determining an absolute longitude in those days. Observations for its determination were taken at Madras during three different periods—commencing in 1787 and terminating in 1847—and the three results, which differ *inter se* by more than four minutes, have been adopted by the Indian Atlas, the Survey Department and the Admiralty respectively. Imagine the confusion! It lasted up to my time at the end of last century, and has only been finally adjusted by the telegraph. Now we really know where the Madras Observatory is.

This, however, did not interfere with the prosecution of Lambton's great work—the initial series of that magnificent scheme of geodetic triangulation which is dealt with in the ponderous volumes of the Indian reports. It was the temper and the scientific enthusiasm of the man which carried him through. The mere conveyance of so heavy an instrument to the tops of the hills selected as observing stations must have involved an army of carriers, and of jungle clearers. Here and there it was necessary to make use of pagodas, or high towers, and it was whilst being hauled up to the summit of the Tanjore pagoda that one of the guys carried away, and the instrument was dashed with great force against the side of the pagoda. The horizontal limb was distorted and the tangent screw and clamp were damaged. This would have disheartened most men; but we find Lambton shut up in his tent at Bangalore soon after the accident, straightening out the instrument with the assistance of one or two ordnance artificers by an ingenious contrivance of his own, and in six weeks he was back again in Tanjore working with the resuscitated instrument, which indeed had become the prop and mainstay of the Survey until 1830. His energy was unquenchable. At the end of the year 1818 Lambton was joined by a young assistant whose name has lived in Indian annals—Everest—and Everest describes his chief as "an old man with a bald head fringed with a few white hairs, about six feet high, well made and muscular. His complexion was fair, and his eyes, dimmed by long service, were blue. When he roused himself to adjust the great theodolite they shone with lustre, and his limbs moved with the vigour of full manhood." But this was nearly the last flicker of energy, and in June, 1819, he gave up triangulating. He had subjected his assistants recklessly to the same exposure in the worst jungles of India that he faced himself, and Everest had been invalided to the Cape. When he returned in 1822, he was only in time to see the last of his old chief, who died still working in harness on the road from Hyderabad to Nagpur. For many years Lambton received no sort of encouragement from the Government or from any scientific society. It was only when he was made a corresponding member of the French Institute

that the Royal Society conferred on him a fellowship. This was not till 1817.

From John Lambton's beginnings the gradual extension of a complete system of geodetic measurement of the whole vast area of the peninsula has been the work of nearly a century. It may be said to be complete now, but there is still the rounding-off of outlying regions to be considered, and the Great Trigonometrical Survey of India, with its immense record of geodetic investigations—unequalled by that of any other country, excepting perhaps Russia—is still alive. Possibly the word "*finis*" will be written at the end of the last volume of those records by the present Surveyor-General, Sir Sidney Burrard. This is the fundamental basis of all our map-making. It has given us the framework, or anatomy, of India, and on this framework an enormous series of maps, geographical, political, military, and cadastral, has been based. Whatever may be the destiny of India in the future, it must stand as an everlasting testimony to the scientific industry of the British nation. It can never be effaced so long as stone walls can contain the records. But whilst the prosecution of scientific work of this nature within the limits of the Indian peninsula, the painstaking record of infinite observations and the mathematical processes of their reduction at a headquarters office, does not lend itself much to romance, it does lay the foundations of other investigations which are not so strictly scientific, connected with the mapping of India and its borderlands, which may be full to the brim with weird experiences and extraordinary happenings. The ordinary humdrum business of land surveys progressing from year to year has been broken often enough by incidents which it is delightful to recall, and amongst them it is those generally which deal with the Himalayas that are the most striking.

At the beginning of the nineteenth century information about the Upper Himalayas was scanty and apocryphal. It was derived from Chinese sources through Jesuit missionaries, who had been busy in Tibet long before then. A map of Tibet had come into the hands of Father Regis, at Pekin, as early as the year 1711. The worthy father represented its inaccuracy to the Emperor Kanghi. The Emperor despatched two lamas who had been educated by the Jesuits at Pekin to make a better one. They were to visit Lhasa and the sources of the Ganges. In 1717 this map was published in Paris, and this was the source of our knowledge of Tibet and the course of the Sanpo (the Upper Brahmaputra) until the days of the native explorers of the Indian Survey. In 1796 the first surveying expedition into the Himalayas was organised, with the object of determining the source of the Ganges, and it was only in 1805 that the immense height of the Himalayan peaks in Nepal was appreciated; so that we may say that it was just about the beginning of the century that this land of romance beckoned to the explorer to follow some of its fascinating paths and to struggle to the attainment of its vast altitudes. Imagine the sensations of those early observers as they wandered slowly along the borders of the mighty Himalayan torrents through the narrow ways of the foothills, overwhelmed with the richness and the sweet oppression of sub-tropical vegetation, ever gaining something in altitude, till the hills on either side presented wider slopes of slippery grass festooned with flowers as in Kashmir, or else were blankly bare and prohibitive except where they touched the foot of the pine and rhododendron forests, skirting the rugged buttresses of the snow-capped heights. The dawning sensations of reaching to something infinitely high and mysterious is lost in these latter days in the dust and clatter of the tonga or of the mountain railway. But there was the real spirit of romance brooding over the chequered frost-bound and snow-patched peaks of Badrinath and Bandarpoonch then. The tales of Hindu mythology hung in festoons round the seats of the gods; the paradise of the Brahmans was up there, near the sky; all the beauty and the wealth of the mighty Indra were awaiting the pilgrim from the plains. From where the Ganges rushes out in cold torrents from the deep cavern of the Gaimukh it is but a day's stiff climb to the summit of the range intervening between the source of the Ganges and that of the Jumna; and from that range, within an amphitheatre of snow, decked with the beauty of white and purple rhododendron, you may see such a glory of snow landscape as you can find only in the Himalayas. You may find it again in Kashmir, in the Tragbal Pass, or in the eastern Himalayas near Darjeeling; but there is no other of the great mountain systems of the world—not the Alps (which between the Rhone and the Rhine could be dumped into one valley of the main Himalayas) or the Pyrenees, or the Andes—which can strike the imagination dumb with such a realisation of the spirit of romance as can the Himalayas.

It is in this region and beyond it, where the

rock barrier of the Himalayas merges into the plateau of Tibet or the transhimalayan uplands of Kashmir, that the most romantic episodes of the Indian Survey work have taken place, if we except the transfrontier of the western Indian borderland, the highlands of Afghanistan, and the flats of Baluchistan, with their fringe of wild mountains hedging the Indus border. Centuries ago the Himalayas were crossed by venturesome Chinese pilgrims in search of the truth as presented by Buddhism. There must have been thousands of them, and some few have told thrilling stories of stone-spitting dragons and other horrors which awaited them on their Himalayan travels. Still more centuries ago it was the gigantic geographical elbow, formed by the junction of the Himalayas and Hindu Kush, which witnessed all those amazing irruptions into India of Central Asian tribes, which were the prelude to the first recorded European invasion, viz., that of Alexander the Great. Persians, Assyrians, Medes and Parthians all had a look in before the Greeks came. They all pulled up at the Indus, and decided that the hot plains of India were not good for their constitutions. There is consequently a wealth of legend about these regions which it has been to the infinite interest of the Indian Survey officials to investigate and unravel, if by chance they could strike a balance between truth and pure fiction. Farther to the west they have struck the tracks of a great mediæval Arab commercial confederacy who, long after the Greeks, occupied the Indus valley and spread out their commercial enterprises till they had riddled all Asia with their tracks. And they, too, have left their records. So that there has been a substratum of tradition on which to found a series of ancient romances which might easily fill volumes had one the energy and wish to write them. It was the northern Himalayas and Tibet that offered the first field for pioneer research, both as a field for science and for adventure. Some of the most stirring incidents of survey investigations occurred during the prosaic progress of scientific observation. We can imagine the sensations of Everest, for instance, when he figured out in his computations that he must have been observing to the summit of the highest mountain in the world without knowing it. We can picture Bassevi with the spout of a boiling kettle near his mouth, inhaling steam to check the pneumonia which killed him, whilst recording the beats of a pendulum of a measured length to determine the effect of that gigantic upthrow of mountains on the force of gravity. We can imagine Tanner facing the full majesty of Nanga Parbat as it rose from the Indus to its summit when he found himself gazing up and down through 24,000 feet of mountain side. And nothing in its way more thrilling has been done than the passing of our Indian triangulation right through and over the Himalayas to a junction with the Russian surveys, so as to bring Petrograd into direct measurement with Calcutta. The story of it is a splendid record of dangers and difficulties overcome by steady, persistent, determined effort. But these not altogether ordinary incidents in the regular progress of work would probably give place in popular interest to the extraordinary achievements in the work of Asiatic exploration which have been accomplished by specially trained native agents. It is not easy to train the Asiatic to habits of close observation in unaccustomed fields. Heredity and instinct alike make him intensely conservative in habits of thought. He will not lift himself readily out of his environment, and, as a rule, the manners and mode of life, the idiosyncrasies of other peoples, are to him matter of profound indifference. I take it that this is, after all, the same everywhere amongst the untravelled communities of mankind. A narrow outlook means a narrow imagination, and it may be a mistake to suppose that the Asiatic, slow of speech to convey an impression, is not as capable of receiving those impressions as the average European. The Chinese pilgrims who tramped the weary way from Pekin to Lhasa and from Lhasa to Peshawar and Benares, and who now and then (about once in a century and perhaps one in a thousand) kept a rough descriptive log of their journeys, are only aroused to enthusiasm by the evidences of their faith which they find *en route*—the temples, the monasteries, the stupas and the sacred trees—and do not trouble to give any record of the nature of the scenery they passed through, or the people they met, though they may have much to say about the difficulties and risks of the road. Indeed, there is some very graphic writing about Himalayan tracks.

Mediæval Arab commercial travellers and geographers are much more instructive; but then they were probably the best educated and most enlightened travellers of their time. The Indian Survey began by enlisting the services of the best educated amongst those whose nationality and environment rendered them likely subjects for the work of exploring the

high tableland of Asia amongst people who were notoriously hostile to strangers. This was at first. Afterwards selections were made in every class of native society, especially from the military, where it was comparatively easy to judge the promise of ability and enterprise in the comparatively raw product before undertaking the long and expensive work of special education. At first, however, it was the village schoolmaster, the priest, and the travelling lama who offered the best material to work upon, and the results were certainly surprising. If there appeared to be a want of intelligent appreciation of the opportunity thus opened for gaining knowledge of the world and witnessing something of its wonders, there was no such want so far as the processes of route-surveying and the acquisition of simple geographical conceptions were concerned. That process of keeping a sordid record from hour to hour and day to day of the compass direction of the route to be followed from point to point, and the number of paces which were taken in the day's work, implied a concentration of thought on a monotonous and dull routine which would have maddened any imaginative European. Yet never a pace was missed nor a bearing wanting in a record of possibly years' duration, and the pilgrim, armed with a compass and a rosary to help him count his steps, with a false bottom to his box wherein was concealed a sextant to enable him to take simple observations for latitude when opportunity offered, would turn up at the end of a journey with a smiling face and a clean record. Even if he had the bad luck to fall on evil times, to be sold as a slave, or to be robbed and maltreated, his records, concealed in the lining of his coat, in his turban or his waistband, would usually be all there, and his keenness in the evolution of the resulting map work would be absolutely absorbing.

Stories of the astonishing exploits of these adventurers would fill a volume. It is true that they were slow to relate them. The details had often to be dragged out bit by bit. It was thus that the old Kumaon schoolmaster, Pundit Nain Sing, traversed Tibet for the first time from west to east. It was then that we learnt of the vast wealth of Tibet in gold, and that we were able to reduce the romances of the ancient Greeks (who dealt freely with such marvels as gold-digging ants amassing heaps of gold which were guarded by fierce dogs) to a more reasonable hypothesis, which proved once again that there was ever some distorted substratum of truth underlying the wildest tales of Ktesias and his kindred. It was then that the vast plateau region of Tibet was first opened out to the eyes of our imagination—the wide bare spaces of wind-swept upland, the frosted white-edged lakes of intense blue beneath the unclouded azure of the sky, the lines of pilgrims making their silent way to Lhasa, and the dreamland of that green valley of the Upper Brahmaputra with its monasteries, its temples, and its whitewashed towns. But it was that marvellous adventurer who figured as "A—K" in our lists who really first introduced us to Lhasa itself, long before the days of the Younghusband Mission. It was he who made the early plans of that weirdest of sacred cities of the East, and gave us a far-away look in at its temples and processions, its wealth of ancient relics, and the quaintness of its religious rites—strangest of which, perhaps, is the yearly selection of a scapegoat for the sins of the people, the wretch who throws dice with the mayor of the town for the privilege of having all the multitudinous sins and immoralities of the townsfolk shaken out of a yak's tail on to his head, and who always loses the throw. Finally he is thrown out of the community with many rites into the wilderness to die. Then there was the romance of the Brahmaputra. How did it get through that savage barrier of mountains to become the Brahmaputra of India? It was old man Kinthup who practically solved this problem; but I regret to say that years elapsed before the wise men of the East in political array would accept his story as anything better than fiction.

Kinthup was sold as a slave for years. He lost his instruments, but he never lost his way, and he exploited the wonderland of Eastern Tibet in spite of all misfortunes. His evidence as regards the Brahmaputra was considered conclusive by such Indian geographers as were best able to check his narrative. Thanks to the exploits of that splendid young traveller Captain Bailey, Kinthup now lives in honoured retirement with the halo of truthful adventure crowning his scanty grey hairs. His was a live romance.

On the western frontier no less than on the northern are there many thrilling tales which might be told of surprising happenings to those who have been despatched to complete the mapping of wide regions in Afghanistan which are even now only partially known. There was a man in my frontier survey party named Sheikh Mohiudin; he was a brilliant draftsman, a most determined explorer, with a thirst for

geographical information which I have never seen surpassed. But he was a man of ungoverned temper and frightfully rash. He plunged boldly into the deserts north of the Helmund River, and was found after many days dead of thirst with his small party around him. Only one escaped, and he had carried the unfinished map wound under his waistband and so preserved it from damage. He was picked up unconscious by a passing Afghan from the edge of the moist bed of a pool which had probably saved his life, and he was finally restored alive to his party, and through him was the fate of the others known. Indeed, that western frontier is the very home of romantic adventure still, but it is by no means usually connected with Indian Ordnance surveys.

I will conclude with a reference to one occasion on which my own feet trod very closely on the skirts of Greek romance, and which might almost be a story from dreamland. On the pretty flower-bordered Mall at Peshawar, looking northward from the cantonments over the city, the view is closed in by the dark line of frontier hills on the far side of the open plain. But at one point, just showing above the line there, whenever the prevailing frontier atmosphere of dust admits, are three knolls or peaks which might almost be mistaken for a part of the near ridges, but which are in reality many miles beyond them. They belong to the crest of a curved offshoot or spur running out eastward from the Kunar Hills into the Swat country, a comparatively small and isolated mountain system known as the Koh-i-Mor (the mountain of Mor). This is described by classical writers (notably by Arrian) as forming part of the country visited by Alexander the Great when he made his momentous march through the north-west of India. There is no great difficulty, now that we have complete geographical knowledge of all that lies between Kabul and the Indus north of the Khaibar route, in identifying generally, and step by step, the scenes of the Greek engagements with the fierce hill tribes of the north, some of whom are represented in these hills to-day. Place names have changed, but the rivers have held to their courses, and it is surprising how many of the old Greek names are to be recognised even now. I have never been able to ascend the Koh-i-Mor: so far as I know, no European officer has ever done so; but I have been on the neighbouring hills, and the character of the scenery and the vegetation is undoubtedly the same throughout this wild borderland. The wild vine and the ivy of classical reference trail over the rocks and festoon the broken sides of innumerable gullies in rank abundance, and from the wild vine a certain detestable wine is derived, which in these degenerate days would certainly not be worthy of Greek libations. On the southern slopes of the Koh-i-Mor there existed some fifty years ago, according to the early Indian Survey atlas sheets, a large scattered village called Nuzar, or Nusar. It has apparently disappeared—at least, I could find no really sound confirmation of the story of its existence under that name in 1894, although I made diligent inquiries in localities as near the mountain as I could get. I have no doubt, however, that it did exist, for it must have been here precisely that the historical incident occurred which describes Alexander as sparing the leading citizens of Nysa (or Nissa) because they claimed a Greek origin like his own. Some of you no doubt will remember the story. This was after he had been as far east as the Indus, where he fought the memorable fight of Aornos, when he returned westward to hunt the brother of Assakenos, who had taken refuge in the Chitral hills. These worthy citizens of Nysa claimed to be descended from the Greeks who in a dim and distant past had penetrated into the Indian borderland under one Dionysos. What they said was this: "The Nysæans entreat thee, oh king, for the reverence thou bearest to Dionysos their god, to leave the city untouched . . . for Bacchus . . . built this city for an habitation for such of his soldiers as age or accident have rendered unfit for military service. . . . He called the city Nysa (Νύσον) after the name of his nurse. . . . The mountain also, which is so near us, he would have denominated Meros (or the thigh), alluding to his birth from that of Jupiter." Now Arrian, who wrote Alexander's history 100 years later, says: "The city was built by Dionysos, or Bacchus, when he conquered the Indians, but who this Bacchus was, or at what time, or from whence, he conquered the Indians, is hard to determine." Arrian, on the whole, has proved to be a very passable and fairly accurate historian, and there can be little doubt that there were early irruptions into India from Greece long before the days of Alexander, and that this led to a fusion between the Pelasgic invaders and the natives of the country which was more definite and more systematic probably than that which must have occurred during the subsequent Greek occupation of Baktria and the Indus valley. Elsewhere we read of Bacchic festivals under the shadow of Meros, of wild

bands of dancing men and maidens clothed with leopard skins, their spears garlanded with ivy and their heads with the vine, on the green slopes of Meros — a truly delightful reminiscence of the romance of classical mythology to the heat-weary Anglo-Indian gazing at the ribs and ravines of the Koh-i-Mor. So far as Alexander is concerned, then, after sacrifice upon the mountain, the incident ends.

In the winter of 1894–95 I was at work within sight of the Koh-i-Mor, determining the position of a boundary which, amongst other purposes, should divide Kafiristan from Chitral. I had the luck to be able to penetrate some little distance into the country of these inscrutable people, the Kafirs, and to enjoy the opportunity of discussing some of their manners and customs with them. Amongst others was the custom of singing hymns and executing dances in honour of their war god, Gish, on the occasion of any specially successful raid into the territories of their Mohammedan neighbours. I obtained the words of their war hymn, and with the assistance of a Chitrali interpreter I got what I believe to be a fair translation of it. Imagine my surprise when it proved to be a veritable hymn to Bacchus, referring unmistakably to the origin of his birth from Meros, the "three-horned" hill, and appealing for further victories! It was not so very long ago that the Kafirs spread over the Koh-i-Mor to the confines of the Swat valley. They have ceased to do so, but they still cling with tenacity to the tradition that the mountain was once their own. And so we got to the back of the strange insistence of the Kafirs that they are of Greek origin—a tradition which for long years has been a puzzle to Indian administrators. It was an old tradition twenty-two centuries ago, when Alexander passed their way. There are certainly various little conventional habits amongst them which differentiate them from the Oriental, such as sitting on stools instead of squatting like the native; but there is no time to go into further details, nor is this the place for anthropological disquisition. It is but one out of many experiences which befall the Indian surveyor which carry him just for the time out of the routine world of scientific investigation and survey progress into realms which more closely border on real regions of romance.

DISCUSSION.

The Chairman (Dr. Dugald Clerk, F.R.S.), in opening the discussion, said the author had given a most interesting, and indeed a most romantic, address. He had shown very clearly the romance of surveying, the adventure and search into the unknown. Romance was not confined, however, even to such adventurous circumstances as those described by the author. Everyone felt the glory of the adventurer and the discoverer, but the romance of the knowledge of the earth, and of all the properties it contained, was necessarily dependent upon such work as the great triangulation to which Sir Thomas had alluded. Before any idea could be formed of the universe at large, it was necessary to know everything about the earth—its shape and its weight, and in that respect the romance of the subject had visited even London. The weight of the earth was first determined by Cavendish, about the beginning of the last century, in Bedford Square, by a rather rough instrument, and since Cavendish's determination English observers had worked hard at the subject. The final, and perhaps the most complete determination of the weight of the earth was made by Professor Boys, who had frequently lectured at the Royal Society of Arts. Boys's discovery of the quartz fibre made it possible to determine the weight of the earth with great accuracy, which, if it had not been for that discovery, would have been impossible. The early determinations of the weight of the earth were made with a silk fibre, a torsion balance, and large weights. The whole principle of the determination of the weight of the earth depended on the attraction between a small weight and a large weight, and determining from that the relative attraction of the earth, and for that purpose it was necessary to know the dimensions of the earth. Given the weight and dimensions of the earth, everything else could be calculated. Without that knowledge all that was known was the relative weight. Professor Poynting also determined the weight of the earth, and made the most romantic discovery that light had pressure. So that even in London there was a certain amount of romance. There was the romance of the discovery of the countless suns of the universe, the rate at which they came to the earth, and the general purpose, if any purpose at all could be traced, of that great universe, all depending and resting upon trigonometrical survey. Without that fundamental knowledge it was impossible to go any further. Romance existed all over the world. There was nothing more exciting, even to an inventor in designing a gas-engine, than to see for the first time some of his ideas actually at work.

Mr. Douglas W. Freshfield (President of the Royal Geographical Society) said it was always a pleasure to hear an address by an expert on his own subject, more particularly so when that subject was one in which the listener had taken much interest for many years. It was some forty years ago since he was first brought into connection with the direction of the Geographical Society, and since then he had been more or less in contact with officers of the Indian Survey. In one sense his object, as the Secretary of the Geographical

Society, had been to endeavour to procure the use of so many of the sheets of the Survey as could be communicated to the public, without political danger, for use by travellers in the first place, and for the construction of other maps on a small scale in the second place. In that task, which met at times with a certain amount of official obstruction, he received the very valuable support of the Commander-in-Chief in India at that time, Lord Roberts, and a great deal was done to enable the world at large to benefit from the splendid results of the Survey. Another sense in which he was brought into contact with the surveyors was when an International Commission was appointed to measure the glaciers all over the world. The heads of the Indian Survey, in the most generous manner, despite the immense amount of work they had to do, put the services of their officers at his disposal to establish marks in the upper valleys in order to show whether the glaciers of the Himalayas were in a period of retreat or advance. He had the pleasure of seeing the part of the Himalayas above Darjeeling fifteen years ago, and of making a journey round Kinchinjunga, and he then had as his companion and guide one of those wonderful men of whom the author had spoken, the native Pundits, who travelled and collected information in places where no European could go. He took the Pundit over a pass which he had never visited before, and when they arrived back in Calcutta the Pundit wrote him the most eloquent letter he had ever received, in which he expressed the hope that he would recommend him for official commendation and reward for having been through the "jaws of death and the gates of hell." That was his description of a very lofty but not too difficult snow pass. There was one name, Surat, mentioned at the beginning of the paper which suggested to him a pleasing recollection of an old traveller who he was afraid contributed nothing to surveying but a great deal to their amusement. It was at Surat that the Elizabethan traveller Coryat died, very picturesquely, from drinking too much sack on Christmas Day. Coryat was a wonderful man who walked all the way from Jerusalem to Delhi. He had been at the court of the Great Mogul and then went down to Surat to refresh himself before he started back for home through the Khanates. Some letters he wrote had a considerable interest; they were addressed to the Right Worshipful Fraternity of Sirenaical Gentlemen who met on the first Friday of every month at the sign of the Mermaid, and in one of them he sent his deep respects to Ben Jonson. There was one fact about him in which he had been rivalled by a more modern traveller, namely, that on his return to England he hung up his boots as a monument of his exploits. He thought those present would remember a living traveller who did the same thing, or, at any rate, whose boots were shown in Bond Street. He had much appreciated the author's eloquent description of the flowers and the scenery of the Himalayas, and entirely agreed with him, so far as his experience went, that there was no landscape in the world to be compared for combined beauty and sublimity with that which might be seen from the hills halfway between Darjeeling and Kinchinjunga. The Caucasus might, perhaps, have a more tender beauty, and certainly the Mountains of the Moon were weirder, but he thought the palm must be given to that portion of the Darjeeling Himalayas. No doubt at the other end of the range there was a still more wild and savage scenery, but the Karakoram did not possess the vegetation which gave the charm and contrast to the Eastern Himalayas.

Sir Henry Evan M. James, K.C.I.E., C.S.I., said that, like the previous speaker, he was deeply grateful to the author for his most unusually interesting paper. There was one point in regard to it which he desired to emphasise, because it was characteristic of the whole of the officers of the Indian Survey, namely, its modesty. The Indian Survey contained some of the most brilliant mathematicians and astronomers in the world, but they were never heard to blow their own trumpet. He remembered some twenty years ago seeing the present Surveyor-General, Sir Sidney Burrard, in a very remote corner of the Persian Gulf, "shooting stars at night," as he expressed it. He was then making observations to determine the longitude of India, and, although it was such an extraordinarily scientific operation, Sir Sidney was most kind in explaining it to him. He also had the pleasure of knowing Captain John Wood, of the Indian Navy, who, in the early 'thirties of the last century, made a memorable journey to the source of the Oxus. Captain Wood also was an extremely modest man; in his admirable book he hardly ever alluded to his own excellent trigonometrical work. He mentioned, just as an ordinary part of the day's work, during his first voyage up the Indus with Sir Alexander Burnes, his taking by triangulation the height of Takht-i-Suleiman, the greatest mountain in the border of the South Punjab. He also mentioned, quite as a matter of course, that when he advanced over the Pamirs in winter, with the thermometer thirty degrees below zero, he had taken the height above the sea of the great Victoria Lake, and also measured it scientifically. He believed it was a few hundred feet less than the height of Mont Blanc. Captain Wood was a very great man. The author, with his usual modesty, had mentioned none of his own feats. Personally, he happened to know of one, namely, that Sir Thomas had tracked the halts of Alexander's retreating army camp by camp, and if some day he would give a paper on that subject, he was sure the members would be very much pleased and enlightened.

Colonel C. E. Yate, C.S.I., C.M.G., M.P., said that all old Indians like himself were much indebted to the author for having so vividly put on record for the information of the world what the Indian Survey really was, all the hardships the surveyors had to

undergo, and the endurance they displayed. Many of them had given their lives in the prosecution of their duties. The old records of the surveyors were most interesting. Forty years ago he well remembered in wild places in Rajputana and Central India studying the reports of the topographical surveyors who had gone before him to many of those wild spots. The author had alluded to the valuable work that had been done in regard to the surveying of the Persian Gulf. Those services were of the utmost value at the present time, when all Britishers were hoping every moment to hear that General Aylmer had succeeded in linking up his forces with those of General Townshend. They all hoped to hear of the British troops triumphantly entering Bagdad before very long. In the campaign in Mesopotamia Indian troops as well as British had endured harder knocks, and had participated in heavier fighting, than had ever before fallen to their lot. He had no hesitation in saying that he looked forward to Mesopotamia being the prize of the Indian soldier, and he hoped to see canal colonies in the future along the Tigris and the Euphrates very much as they were along the Indus at the present moment. He agreed with all the author said about the work of the Indian surveyors, what splendid explorers they were, and what wonderful work they had done. He was glad to see how that wonderful old explorer, Kinthup, had been proved to be correct by Captain Bailey, and he welcomed the name of Bailey coming to the front again, because Bailey had been an honoured name in India for many years. He well remembered the case of the survey party mentioned by the author in connection with the survey of the deserts to the north of the Helmund River, in Seistan; how the last man of the party left alive was found unconscious with the unfinished map under his kamrbund, and that was a testimony to the faithfulness and devotion to duty of the Indian Survey through all their work.

Mr. W. Coldstream said the author was an able representative of the Indian Survey Department, who was well known for the versatility of his talents in various directions. He was skilled as an artist, and many who had resided at Simla would recollect the watercolour pictures which Sir Thomas from time to time contributed to the Fine Art Exhibition there. Artistic talent seemed to be a frequent endowment of the officers of the Indian Survey. Perhaps it was stimulated by the grand and beautiful scenery amid which their official duties constantly led them. However that might be, a majority of the best pictures in the Simla Fine Arts Exhibitions were contributed by officers of the Indian Survey. One remembered, for instance, the fine works of Tanner, Strahan, Bythell, and Sir Thomas himself; and in recent years Majors Gunter and Cowie, and the present Surveyor-General, Sir Sidney Burrard, were known as excellent artists. As a quondam Indian official, he could speak from experience of the great practical utility of the work done by the Indian Survey. It lay at the very foundation of many of the most important departments, such as those of Revenue and Forest.

Admiral the Hon. Sir Edmund R. Fremantle, G.C.B., in proposing a hearty vote of thanks to the author for his most interesting paper, said there was only one criticism he desired to make in regard to it, namely, that it contained so much about the work of other people and so little about the work of Sir Thomas himself. The author had, as everyone knew, rendered the very greatest services to the Indian Survey Department. Sir Thomas had referred to the surveying of the seas done by the old seamen who went out to India in the early days of the seventeenth century. All the work in that respect that had been done by naval men had been of great service to the commerce of the whole world. The author had referred to the fact that Mr. Lambton, who was apparently a man of very little education, had the great credit of founding the geodetical survey of India. It was a curious fact that one of the greatest surveyors in the Navy, Captain Cook, was also a self-educated man, but, nevertheless, both of those men had done extremely scientific work. Although Cook had very imperfect instruments he made exceedingly accurate surveys, and Lambton was evidently a man of the same type.

Major-General Beresford Lovett, C.B., C.S.I., in seconding the motion, said the story of the Indian Survey was almost unknown except amongst the Anglo-Indian communities, and the author's graphic description of the work that had been done was therefore all the more acceptable. He hoped the author would, on a future occasion, read another paper on his own personal adventures as a surveyor.

The resolution of thanks was then put and carried unanimously.

Colonel Sir Thomas Holdich, after thanking the Fellows for their kind vote of thanks, said he wished particularly to call attention to the very great part the Indian Navy had taken in clearing up the geographical problems connected with India. The Indian Navy had long since disappeared, but there was no reason why it should not receive the credit which was due to it for its work. He desired, in conclusion, to express the thanks of the meeting to Dr. Dugald Clerk for his kindness in taking the chair.

SIXTH ORDINARY MEETING.

Wednesday, January 19th, 1916; the Right Hon. Lord Farrer in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Aiken, Rev. James, M.A., St. Thomas' Manse, Georgetown, Demerara, British Guiana.

Briefer, Michael, Ausco Company Research Laboratory, Binghampton, New York, U.S.A.

Brooks, Edmund D., 89, Tenth-street South, Minneapolis, Minnesota, U.S.A.

Griggs, Professor Edward Howard, A.M., Montclair, New Jersey, U.S.A.

Hemmeter, John C., M.D., Ph.D., Sc.D., LL.D., 739, University Parkway (Roland Park), Baltimore, Maryland, U.S.A.

Howell, Hon. Clark, Atlanta, Georgia, U.S.A.

Lawrence, Thomas Richard, 5, Bellasis-road, Byculla, Bombay, India.

Monserrat, Nicholas D., Hartman Building, Columbus, Ohio, U.S.A.

Randolph Isham, D. E., 1827, Continental and Commercial National Bank Building, Chicago, Illinois, U.S.A.

Ridge, James A., The Ceylon Wharfage Co., Ltd., Colombo, Ceylon.

Sibert, General William L., Presidio, San Francisco, California, U.S.A.

Thorndike, Townsend William, M.D., 20, Newbury-street, Boston, Mass., U.S.A.

Updike, Daniel Berkeley, The Merrymount Press, 232, Summer-street, Boston, Mass., U.S.A.

The following candidate was balloted for and duly elected a Fellow of the Society :—

Bennett, John, 57, Telford-avenue, Streatham, S.W.

The Chairman, in introducing the lecturer, read the following letter which he had received from Lord Eversley, for many years the President of the Commons and Footpaths Preservation Society :—

Abbotsworthy House,
Kingsworthy, Winchester.
January 18th, 1916.

My dear Farrer,

I regret that I shall be unable to be present at the meeting of the Society of Arts to-morrow when Mr. Lawrence Chubb's paper on "Commons" will be read.

The infirmities of age have come upon me, and if present I should be unable to hear either the address or the discussion on it. I should have to content myself with the words *adsum qui feci*, which would be thought boastful.

I have not read Mr. Chubb's paper and am not responsible for it. Not the less, I am certain I should concur in it, for no one knows more of the subject than he does, and no one is more imbued with the principles which I have endeavoured to maintain during the fifty years of the movement.

My only fear, arising from the fact that Mr. Chubb has not submitted his paper to me, is that he may have been induced by his long association with me, to dwell too much on my own efforts and too little on those of others, many of them long ago dead, with whom it was my task and my pleasure to co-operate on the subject. I have warned him against this, I hope not in vain.

Yours very truly,
(Sd.) Eversley.

The paper read was—

THE COMMON LANDS OF LONDON: THE STORY OF THEIR PRESERVATION.

By Lawrence W. Chubb,
Secretary of the Commons and Footpaths Preservation Society.

Of all the many advantages enjoyed by the inhabitants of London, there are few, if any, more prized than the network of commons, parks, and other open spaces to be found in every quarter of the metropolis.

They are of practical value because of their utility as recreation grounds. They have perhaps an even greater value, because they bring to the doors of town-dwellers a message of Nature and a sense of quiet beauty and restfulness which have become essential in these days of strain and stress. Indeed, it is safe to assert that there are now few persons who cavil at the expenditure necessary for the acquisition and maintenance of open spaces, because it has come to be universally realised that a sufficiency of "open air lungs" is only less necessary to the citizen than adequate systems of sewerage and water-supply.

In view of the general recognition of the utility of commons as open spaces, it is somewhat remarkable that the demand for their protection should not have manifested itself until about fifty years ago. There had been slowly growing a latent feeling of hostility to the steady inroads upon commons in general, and metropolitan commons in particular. The feeling was only crystallised into action by the formation of the Commons and Footpaths Preservation Society. On July 19th, 1865, a meeting of gentlemen was held at the instance of Lord Eversley (then Mr. George Shaw Lefevre), at which it was decided to found the society. The necessary steps to organise the new body followed, and on January 24th, 1866, a meeting took place at the Mansion House, under the chairmanship of the Lord Mayor of London, at which the new society was publicly inaugurated. We therefore meet to-day within a week of the Jubilee of the public formation of the society.

Of its original founders the first chairman, Lord Eversley, now only remains, and the society has indeed been privileged in retaining his services, for it has been mainly due to Lord

Eversley's outstanding knowledge of the law of commons, and to his dogged pertinacity, wise judgment, and inspiring enthusiasm that the main objects of the society have been successfully accomplished.

The primary aim of the society was to put a stop to the constant encroachments which were taking place upon commons. Before inviting you to consider the extent and nature of these encroachments, it seems desirable to explain briefly that, in a strictly legal sense, a common is a tract of private land, the soil of which is vested in one person, generally the lord of the manor, but over which other persons, known as commoners, are entitled to exercise certain definite rights or customs. These rights are known as rights of common, and it is only while they remain that the land is a common. They generally include the right to turn out horses, cattle and sheep to graze upon the "wastes of the manor," as the commons are called. Often the commoners are also entitled to cut undergrowth for fuel, or for repairing their fences or houses, as well as bracken for litter, heather for thatching, and peat for fuel. While such rights are exercisable over the common, the lord of the manor cannot now lawfully take full advantage of his proprietary interests in the soil. The fight for commons is the story of the struggle of lords of manors to ignore these rights, or to evade by Parliamentary authority the consequence of their existence.

Greater London, as we shall see, is the happy possessor of about 15,900 acres of land which is still common, or which has been converted into public pleasure grounds by the purchase of the manorial and commoners' rights.

Large as this area is, it is but a small portion of the common lands which once existed in and about the metropolis. The Doomsday Survey gives us a glimpse of what London was like in the days of the Conqueror. It records, for instance, that at Westminster the village nestled round the minster, or church of St. Peter, which Edward the Confessor had built. It consisted of twenty-five houses of the abbot's immediate followers, nineteen homesteads of villeins, forty-two cottages with gardens, and a vineyard of four half-acres. There was sufficient common meadow by the riverside to make hay for a dozen plough teams, and to furnish pasture for the commoners' other cattle. Further around the village lay 1,000 acres of common fields or Lammas lands in acre strips, while on the land side were the open wastes and the common woods, where the swineherd found mast for the 200 pigs of the village. The Lammas lands were commonable, because, although the owners could grow crops upon them, they had to remain open to the pasturage of the commoners' cattle during the autumn and winter months from Old Lammas Day.

The conditions which existed at Westminster were repeated wherever the Saxon system of cultivation obtained a secure foothold. The manorial lords, implanted by the Normans, found that a great part of their manors consisted of common land, and that the commoners were by no means willing that this should be appropriated as the exclusive and private property of their lords. To overcome opposition on the part of the commoners, the barons, in Parliament assembled, passed in the year 1235 the Statute of Merton, an Act which has ever been responsible for bitterness and heart-burnings. It purported to allow the lord of the manor to enclose parts of the wastes of his manor, provided he left sufficient to supply the needs of the cattle of the freehold commoners. It completely ignored the ancient rights and customs of the humbler villeins, the copyholders and the inhabitants generally, and, in practice, it enabled an unscrupulous lord of a manor to disregard the wishes of the village, for the humble yeoman had little to hope for if he were hardy enough to challenge the desires of his manorial chief before judges who are alleged to have lent their aid to those who could afford to pay for it.

Vast areas of common land were appropriated under this injurious measure, and the outbursts of opposition which gave rise to the Tudor agrarian rebellions testified to the sense of iniquity engendered by the Statute of Merton.

Occasionally, however, the lord of the manor found it difficult to overcome the hostility of the commoners to large enclosures of waste lands, and early in the eighteenth century a new method was devised by which the objections of refractory opponents could be overridden. Moreover, in those parishes where the arable land consisted of common fields, held in separate acre and half-acre strips by a number of persons whose strips were hopelessly intermingled, it was seen that for the benefit of agriculture it was desirable to consolidate the individual holdings. The new method of procedure took the form of an application to Parliament for power to effect a partition of the commons in a particular parish or manor. The success of this method was speedily apparent. It provided a

satisfactory means of getting rid of common field cultivation. If it had stopped there little criticism would have been evoked. But speedily the scope of Inclosure Acts was extended to embrace ordinary commons as well. To such Acts strong objections have been raised. They deprived the small commoners of the power of effective local opposition. They could not make their voices heard before a Parliamentary Committee. Nevertheless, Inclosure Acts manifested a semblance of justice, since, upon the partition of a common, all persons legally interested as commoners, or otherwise, were entitled to receive an allotment of the land or other compensation in proportion to the value of their rights.

It is now, however, conceded by most modern historians that in their operation Inclosure Acts were often unjust and baneful to the small farmer and cottager. Such persons, upon the enclosure, received a trivial allotment situate some distance from their homes in lieu of their pasture and fuel rights. With the aid of the common those rights had enabled them to rear a few beasts when their own holdings were under crop. When deprived of the privilege of turning their stock to graze upon a large area of pastureland they were forced to abandon the rearing of animals, their holdings speedily became unprofitable with the extinction of this source of income, and their little properties gradually drifted into the hands of the large landowners. In this way the country lost its race of lesser yeoman farmers, and it is a significant fact that small-holdings are still to be found in any numbers only in proximity to spacious commons, such as the New Forest, or the Fells of the North, and the open hills of Wales. It is equally significant that the Small Holdings Act, 1907, contains a provision enabling County Councils to purchase land compulsorily for the purpose of re-creating common rights to be attached to small-holdings. It may be too late to restore the ancient system of small-holdings, but this modern recognition of the value of commons is an eloquent testimony to the loss sustained by the country when common lands disappeared.

Inclosure Acts speedily became the fashion, and the work of Parliament was congested by a multitude of applications for power to enclose commons. Between 1710 and 1869 no fewer than 4,719 Inclosure Acts were passed, and it is estimated that, by their means, over 5,000,000 acres of common lands were divided.

The counties bordering upon London felt the full effects of the new movement, as the following table will show:—

County.	No. of Acts.	Estimated area enclosed.
		acres.
Middlesex . . .	42	53,615
Essex	67	40,015
Herts	61	61,436
Surrey	80	56,915
Kent	31	7,743
	281	219,724

Included in this total were Acts for enclosing the commons of St. Leonard, Shoreditch, Willesden, Chiswick, Finchley, Edgware, Hornsey, Newington Butts, St. George's, Southwark, Lambeth, Penge, Dulwich, and Croydon. Indeed, more than four times as much common land was enclosed within London proper as the land which has since been bought and dedicated to the public use and enjoyment, and it has often been necessary to buy back as open spaces at building value land which was formerly common. In one instance, that of Hainault Forest, the enclosure of 4,000 acres of magnificent and primeval woodland was authorised in 1851. Owing to the growth of East London, it was, in 1903, found necessary by Mr. Edward North Buxton to formulate and carry through a scheme for buying back 798 acres of this land for the public at the price of £22,430. It had cost no less than £42,000 to grub up the timber in the forest. The London County Council is now replanting part of this area.

From about the year 1860 there gradually arose a movement in opposition to the passage of Inclosure Acts. It had come to be recognised that in and about towns it was imperatively necessary that the health, recreation and comfort of the inhabitants should receive consideration, and that, from the point of view of amenity, commons in their natural state were a real and permanent asset to the community. Moreover, means were sought to restrain the steady influx into cities of agricultural labourers from rural districts. This it was at last realised was in no small degree due to the loss of the commons. No regard had been paid under Inclosure Acts to the interests of the poor, and the lot of the labourer had gone from bad to worse. Added to this, was the knowledge that the preamble of each Inclosure Act which declared

that land was required for the growth of corn was often a farce. This was proved by the fact that no effort was made to cultivate tens of thousands of acres of land which had been enclosed. Indeed, to this day there are tracts of land within twenty miles of London the enclosure of which was decreed seventy years ago in order that corn might be grown, but which have never even been fenced.

For such reasons public opinion slowly formed against the passage of further Inclosure Acts. The first step in the direction of organised opposition was taken in 1865. In that year a proposal was submitted to Parliament for dealing with Wimbledon Common, one of the finest and most spacious commons in the neighbourhood of London.

The lord of the manor, the then Lord Spencer, actuated no doubt by the worthiest motives, propounded a scheme involving the sale of Putney Heath, which formed one-third of the common. The money received from the sale was to be devoted to extinguishing the rights of the commoners and to improving the remaining 680 acres, with a view to dedicating the land as a park.

The lord of the manor proposed to reserve to himself the right to erect a mansion in the park thus formed, and with the part proceeds of the sale of gravel and of outlying portions of the common a rent-charge was to be paid to Lord Spencer, equal to the average of his past receipts from gravel and otherwise.

Judged by the standard of Inclosure Acts, the proposed provision for the public needs was most generous. But the commoners and residents of the neighbourhood naturally resented the sacrifice of over 300 acres of the common and the conversion of the residue into a fenced park.

A local committee, presided over by Sir Henry Peek, was formed to oppose the scheme, and its efforts were stimulated by the appointment, on February 21st, 1865, of a Select Committee "to inquire into the best means of preserving for the public use the Forests, Commons, and Open Spaces in and around the Metropolis."

Of this committee Lord Eversley was fortunately a member. The Wimbledon Common scheme received its consideration, and it heard evidence asserting that the public had no legal rights whatever to the use or enjoyment of the common, and that the commoners were so few in number and importance as to impose no effective barrier between the lord of the manor and his scheme. The committee, of which the late Sir Henry Doulton was chairman, rejected such propositions and promptly reported:—

"That it is not expedient that the Wimbledon Common should be fenced round or inclosed, or that the existing common rights should be extinguished;

"That it is not necessary, and would be undesirable, that any part of the common should be sold;

"That the 20 Hen. 3, c. 4, commonly called the Statute of Merton, by which a Lord of the Manor can inclose without either the assent of the Commoners or the sanction of Parliament, ought immediately to be repealed."

In consequence of these views, the Wimbledon Bill failed to receive the assent of Parliament, and as will shortly be shown the common was afterwards preserved in its entirety.

The Select Committee now extended their inquiries, and later on, in the year 1865, presented a second and lengthy report accompanied by voluminous evidence with regard to metropolitan commons. This report, which is the foundation of the Commons Preservation movement, was drawn up by Lord Eversley and Mr. Philip H. Lawrence, the first honorary solicitor to the Commons Preservation Society, was approved by the chairman and was adopted by a large majority of the committee.

The report enunciated the broad and important principle that "there is no Open Space within fifteen miles of London which can be spared, or which should be reduced in area." It urged that a scheme put forward by the Metropolitan Board of Works for buying up the interests of the lords of manors and commoners at an estimated outlay of £6,000,000 was unwise and unnecessary, since the committee were of the opinion that existing rights of common were sufficient to safeguard the public against enclosure.

As an alternative to the partition of commons, the report recommended that such lands should be regulated or placed under the management of public authorities without prejudice to the legal interests involved. It reiterated in stronger terms its first conclusion that the Statute of Merton should be dealt with on the ground that "the necessity of providing Open Spaces for health and recreation has become paramount to the mere improvement of those lands in an agricultural sense, and seeing that the inevitable result of the inclosure by private individuals of lands in the populous suburbs of the metropolis would be not even agricultural improvement, but building, they

have no hesitation in coming to the conclusion that it is time the Statute of Merton should be repealed."

The need for action had indeed become urgent Finding that Parliament was not disposed to pass further Inclosure Bills for commons around London, many lords of manors had reverted to the older method of enclosure by means of approvement under the Statute of Merton, which had fallen into desuetude in favour of the easier method of partition by Inclosure Act. In every direction commons were being ruthlessly absorbed. Epping Forest was fast disappearing; Berkhamsted Common was bisected; Hampstead Heath was gravely threatened, and such invaluable open spaces as Tooting and Plumstead Commons and Bostall Heath were already enclosed.

It was to combat this wholesale attack that the Commons Society was founded, and those who desire a detailed and fascinating account of the many fights which ensued should consult "Commons, Forests and Footpaths," the work of Lord Eversley, whose unique knowledge of every case places him in a pre-eminent position as an authority, and would justify him in claiming, should he so desire, the title of historian of the movement. I have made frequent use of Lord Eversley's book for the purposes of this paper.

The first tangible outcome of the formation of the Society was the passage of the Metropolitan Commons Act, 1866, which forbade the enclosure of commons within the Metropolitan Police District, and which set up the regulating machinery recommended by the Select Committee in 1865. This Act has already led to the permanent protection of no less an area than 4,171 acres of commons in and around London.

Because of their dramatic interest, however, the many bitter contests waged against enclosures under the Statute of Merton naturally appeal most to the imagination.

Hampstead Heath formed the subject of the first fight. The Heath is perhaps the best-beloved of the numerous open spaces situate within easy reach of the City. It is the traditional Mecca of the poor upon Bank Holidays. Acting as a barrier between the steady march of bricks and mortar and the green fields, it commands fine views over the smoke banks of London as well as over the rustic part of Middlesex, and its sylvan setting renders it a delight alike to the artist and lover of natural beauty.

The Heath was a common within the manor of Sir Thomas Maryon Wilson, and for many years that gentleman had made repeated but, happily, fruitless attempts to induce Parliament to allow him to deal with it as part of his building estate. Before the Select Committee of 1865 Sir Thomas "asserted his absolute interest in the land, free from any common or other rights, and his intention to make what use of it he could by leasing it for building purposes," complaining that by the outcry raised against him he had been deprived of £50,000 a year.

True to his threat, Sir Thomas commenced to build houses upon the most conspicuous parts of the Heath. His action was promptly challenged by Mr. Gurney Hoare, who brought a suit against Sir Thomas on behalf of the commoners of the class to which Mr. Hoare belonged. Lord Romilly, the Master of the Rolls, overruled technical objections taken to the form of the legal proceedings, and established the society's claim that a single commoner might take proceedings on behalf of all representatives of his class. The issues of fact involved in the suit were directed to be tried by a jury. Before this could be done Sir Thomas died. His successor manifested a different disposition, and announced that he did not intend to proceed with the buildings upon the Heath. An arrangement was reached by which the Metropolitan Board of Works bought out the manorial rights for £45,000. Before the suit originally commenced, Sir Thomas Maryon Wilson had demanded no less a sum than £400,000 for the Heath. The outcome of the expensive legal proceedings thus fully repaid Mr. Hoare, his friends, and the Commons Society for embarking upon litigation.

The Heath then extended to 268 acres. It was increased in 1889 by the addition of Parliament Hill Fields, purchased for the sum of £300,000 after five years' strenuous exertion. In 1898 it was further enriched by the addition of Golders Hill, and in 1907 the Heath was raised to its present area—667 acres—by the acquisition of 80 acres of land around which the new Hampstead suburb is being built under the watchful care of Mrs. Barnett. It is to be hoped that, at some future time, the frontages of Ken Wood may also be added to Hampstead Heath, for they are indispensable to the full enjoyment of this magnificent open space.

Berkhamsted Common is not, strictly speaking, a metropolitan common, for it lies twenty-five miles away from the city. But no account of the movement would be complete without a

reference to the costly and successful suit which led to the protection of this elevated and beautiful tract of land. It has an area of about 1,150 acres, and was formerly in an estate of the Duchy of Cornwall. In 1862 this estate was sold by the Duchy to the trustees of the late Lord Brownlow, who at once endeavoured to secure the sole control of the common. As a first step the trustees induced the villagers to agree to the diversion of a broad grass drive which traversed it from south to north. Then gravel pits were dug in such a position as to stop another drive, and several small enclosures were effected as a tentative measure.

Some of the commoners objected to the enclosures, and the trustees promptly sought to meet their objections by purchasing their rights. The common, however, had been largely resorted to by the inhabitants of Berkhamsted, who had cut fern and gorse, not in respect of ancient tenements but as inhabitants. As a concession to these persons the trustees proposed to present a recreation ground of forty-three acres to the town, subject to the condition that the common should be freed from all rights of common within six months. Forty-four of the freeholders and copyholders were induced to fall in with this scheme, and the trustees felt themselves sufficiently secure to proceed with an enclosure upon a great scale. Accordingly, in February, 1866, the agent of the estate erected high iron fences in two lines across the common, enclosing 434 acres and leaving two completely detached portions at each end. The fences effectively stopped passage over the common, and obviously were designed to facilitate the appropriation of the entire open space.

In the *Times* newspaper, Lord Brownlow's solicitors asserted that "the public has no more right to pass over the common than a stranger has to pass through a commoner's private garden, and that even a copyholder tenant of the manor, entitled to common rights, can only go upon the common in order to place his sheep there, and to look after them when there, and, therefore, with that qualification, any person who drives, rides, or walks across the common out of the public highway is a trespasser."

This arbitrary attitude was promptly challenged, for amongst the commoners was Mr. Augustus Smith, whose life's work in the Scilly Islands had marked him out as a man of strong character and great courage. Lord Eversley, acting on behalf of the society, was able to induce Mr. Smith to champion the cause of the commoners.

It was decided to abate the enclosure by the forcible removal of the fences. The story of this removal cannot be better told than in Lord Eversley's own words:—

"It was arranged with a contractor in London to send down at night to Berkhamsted a force of 120 navvies, for the purpose of pulling down the iron fences in as short a time as possible. On March 6th, 1866, a special train left Euston, shortly after midnight, with the requisite number of labourers, skilled workmen and gangers, armed with proper implements and crowbars. At this point the operation nearly miscarried. The contractor, it appeared, had sub-let his contract to another person. The two met together at a public-house near Euston Station the evening before the intended raid and drank so freely that neither of them was in a condition to lead the force into action, and the navvies arrived at Tring without a leader, and with no instructions. Fortunately, Mr. Lawrence (the society's solicitor) had sent a confidential clerk to watch the proceedings from a distance, and this gentleman, perceiving the difficulty, took the lead of the force.

"A procession was formed at the station. A march of three miles in the moonlight brought them to Berkhamsted Common, and the object of the expedition was then first made known to the rank-and-file. The men were told off in detachments of a dozen strong. The substantial joints of the railings were then loosened by hammers and chisels, and the crowbars did the rest. Before six a.m. the whole of the fences, two miles in length, were levelled to the ground, and the railings were laid in heaps with as little damage as possible. It was seven o'clock before the alarm was given, and when Lord Brownlow's agent appeared on the scene he found that Berkhamsted Common was no longer enclosed. It was too late to do more than make an energetic protest against the alleged trespass.

"Meanwhile the news spread, and the inhabitants of the district flocked to the scene. Gentlemen came in their carriages and dog-carts; shopkeepers from Berkhamsted and farmers in their gigs; labourers on foot tested the reality of what they saw by wandering over the common, and cutting morsels of the flowering gorse, to prove, as they said, that the land was their own again. Thus were the 430 acres restored to the common, and two miles of iron fences removed."

Proceedings were forthwith commenced against Mr. Smith, who brought a cross suit in the Chancery Division against the Brownlow

Trustees, claiming on behalf of himself and the other commoners that their rights should be ascertained, and that the lord of the manor should be restrained from interfering with them or from enclosing the common. For four long years the suit dragged on, and finally, in 1870, Lord Romilly, who tried the case, gave judgment on all points in favour of Mr. Smith. Thus by Mr. Smith's splendid action, fought under the guidance of the Commons Society, this beautiful stretch of down and woodland was saved from extinction as an open space, to form a lasting monument to one whose purse and sympathy were ever at the disposal of worthy public causes.

Following close upon the Berkhamsted suit came noteworthy struggles with regard to several South London commons. In 1865 Plumstead Common, of 110 acres, and Bostall Heath, of 55 acres, and 25 acres of Tooting Common were enclosed. The two former commons formed part of the wastes of Plumstead, the lords of the manor being the Fellows of Queen's College, Oxford, whose steward, after a series of acts of aggression and encroachment, enclosed about 74 acres of Plumstead Common, the whole of Bostall Heath, and a village green 5 acres in extent.

Here, again, the public were fortunate in their champions, for Sir Julian Goldsmid and Mr. John Warrick were found ready, with the backing of the Commons Society, to challenge the legality of the enclosures.

The College set up a claim to be entitled to enclose under the Statute of Merton, with or without the consent of the freeholders, and asserted that the rights of common had been abandoned or extinguished.

On every point the lords of the manor were worsted, both in the Chancery Division and in the Court of Appeal. It was definitely laid down that one freehold tenant of the manor could sue in defence of rights of common on behalf of himself and all other freehold tenants, and that his rights of common were not lost if he neglected to pay his quit rents to the lord of the manor. This common now belongs to the London County Council, together with 62 acres of a beautiful wood adjoining it.

Tooting Graveney Common is one of the most delightful of our southern open spaces. Clumps of gorse and underwood, interspersed with well-grown trees, and a broken and irregular surface successfully simulate an unspoiled rural common of considerable size. It is, nevertheless, only 66 acres in extent, and is surrounded by a dense population. Its near neighbour, Tooting Bec Common, is 151 acres in extent.

Tooting Graveney is in the manor of that name, and the well-preserved Court Rolls show that it possessed all the attributes of normal manors. The common and some copyhold tenements were bought in 1861 by a Mr. W. S. Thompson for the sum of £3,650, it was hoped, by his neighbours, in order to preserve it for the public use. But "hope told a flattering tale," and after Mr. Thompson had endeavoured to induce the Inclosure Commissioners to bless a proposal to enclose all, and, subsequently, a portion of the common, he fenced in 25 acres of the land in 1865. Three years later the fences were broken down by the commoners, and on the advice of the Commons Society proceedings were commenced against Mr. Thompson by Mr. Betts and two other commoners. Again the plea was put forward that by non-user the rights of common had been lost, and that, as lord of the manor, Mr. Thompson was entitled to enclose the common under the Statute of Merton, since, as it was urged, the freehold tenants were not aggrieved.

The hearing of the action lasted for eleven days, before Lord Romilly, and, on appeal, for six more days. In each count the commoners triumphantly vindicated their claims. "Mr. Thompson," said Lord Hatherley, in pronouncing the judgment of the Court of Appeal, "had purchased the manor for a comparatively small sum, and if he had succeeded in depriving the freeholders of all rights would have made a very handsome profit, and he seemed to have considered that, being the lord of the manor, his title could not, without difficulty, be displaced. In that speculation he had been disappointed."

Tooting Common was thus rescued from the hands of the speculative builder, and represented one more link in the long chain of striking victories which marked the advent of the Commons Preservation Society. The manorial rights in Tooting Graveney Commons were subsequently bought by the Metropolitan Board of Works.

By way of contrast it is only fair to note that all lords of manors did not show the same complete disregard of the public interests in commons as was manifested at Tooting Graveney, Plumstead, Berkhamsted and Hampstead. For instance, in the case of Streatham Common, which is distant less than a mile from Tooting Bec, the Ecclesiastical Commissioners, as lords of the manor, not only became willing

parties to a regulation scheme, but also conveyed their manorial rights to the public for the nominal sum of £5.

This common is 66 acres in extent, and rises to a considerable height over the surrounding district. It is pleasantly undulating and picturesque, and, at the instance of a committee formed by Mr. Stenton Covington, it has recently been enriched by the addition of the charming grounds of the Rookery, in which is to be seen the ancient pump-house of Streatham Wells.

In chronological order Wimbledon and Wandsworth Commons were the next to be saved.

The rejection by the House of Commons of the arrangement proposed by Lord Spencer in 1865 led to an estrangement of the relations between the lord of the manor and the commoners. The owner showed that he took a somewhat narrow view of the legal position and of the public interests; and the commoners, on their part, felt that their rights were so extensive as to render their approval necessary to any proposals with regard to the commons. Lord Spencer was lord of the manors of Wimbledon, Putney, Battersea and Clapham, and in consequence of the acute differences of opinion which existed as to the manorial and commoners' rights, proceedings were initiated by Sir Henry Peek against Lord Spencer in 1866. The unexpected discovery that, in respect of a large area of land not previously taken into consideration, common rights existed, rendered possible a compromise, and the litigation was happily abandoned.

The compromise provided that Lord Spencer should convey all his rights in Wimbledon Common and Putney Heath to a board of eight conservators, receiving in return an undertaking for the payment of a perpetual annuity of £1,200. In order to raise this sum, and to meet the expense of maintaining the common as an open space, the novel principle was introduced of levying a rate upon all dwelling-houses annually assessed at or over £35 situate within three-quarters of a mile of the common. The occupiers were to be taxed in proportion to their nearness to the common in one quarter of a mile zones, an interesting and successful experiment which might be repeated in other neighbourhoods where the provision of an open space is calculated to lead to the betterment of surrounding property. This arrangement was confirmed in 1871 by a special Act of Parliament, and Wimbledon may be congratulated upon the consummation of a scheme which fully justified the strenuous opposition to the original proposals.

Wimbledon Common thus saved was already one of the most spacious, as it is also one of the best-known and most beautiful open spaces in the neighbourhood of London. The rapid development of the district has rendered necessary a further effort to protect from disfigurement that which had only been saved at the cost of so much sacrifice. A committee, inspired by Mr. Richardson Evans, has been strenuously working for over six years to acquire the land lying between the common and Richmond Park and along the borders of Beverley Brook. The bulk of this land has been already secured and added to the common. The completion of the scheme would protect the amenity of the existing land and furnish an unbroken area of open space extending from Putney and Wimbledon to Kingston, Ham and Richmond.

Wandsworth Common was dealt with on somewhat similar lines to those which ensured the safety of Wimbledon Common, though without the rating provisions. In consideration of an annuity of £250 the interests of Lord Spencer were conveyed to a board of conservators, to be afterwards transferred to the Metropolitan Board of Works, and subsequently to the London County Council.

This open space is an object-lesson of the manner in which commons suffered in past days. It is now 175 acres in extent, but until 1782 had more than double that area. Constant encroachments took place for private or semi-public purposes, the last being the enclosure after the Crimean War of 60 acres to form a site for the Royal Patriotic Society's Schools, the commoners having generously surrendered their rights in order that this might be accomplished. Twenty acres of this land were bought back three years ago and added to the common at a total cost of £12,000.

This common, too, was cruelly used by the London, Brighton and South Coast and London and South Western Railway Companies, whose disfiguring lines were allowed to cut it up into disjointed blocks, gravely interfering with its utility as an open space. Railway companies have indeed much to answer for, since, in scores of cases, their lines would seem to have been deliberately planned to traverse the maximum quantity of common land. Such harmful attacks were carried out with impunity until the Commons Preservation Society fought the Private Bills in Parliament, and by defeating

many injurious schemes compelled railway companies to recognise that the risk of losing their Bills was too great if, in order to cheapen the cost of construction, their lines were planned in such a manner as seriously to injure commons. Every railway, water, and other private Bill now introduced into Parliament is closely scrutinised by the society, which, thanks to general support from all political parties, has been the means of saving tens of thousands of acres of common land from appropriation.

It is now necessary to tell the story of the preservation of Epping Forest, perhaps the most beautiful as it is the largest of London's open spaces. The forest, as it exists to-day, is 5,559 acres in extent. Great as is this area, it is but a shred of the once vast Forest of Waltham of which it formed part.

It runs from Wanstead Flats to Epping as a belt of sylvan scenery over thirteen miles in length. Here and there—as at High Beech—are to be found groves of well-grown beech and oak. For the most part, however, the forest consists of spacious woods of pollarded hornbeam and oak, broken at irregular intervals by ancient clearings and leafy glades.

Epping was a Royal Forest, which is defined by Manwood as " a territory of woody grounds and fruitful pastures, privileged for wild beasts, and fowls of forest, chase and warren, to rest and abide there in the safe protection of the King, for his delight and pleasure." In those far-off days when Royalties amused themselves by chasing the deer, everything in the forest was subordinated to the sport. No fences around ancient enclosures within the ambit of a forest must be sufficiently high to exclude a doe with her fawn; the cottager must not drive the deer from his crops, and no buildings could be erected " because of the increase of men and dogs and other things which might frighten the deer from their food."

The Crown rights were gradually diminished by sale or disuse, but even in 1793 the area of the open forest was reported by the Land Revenue Commissioners to be 9,000 acres. The forest was already largely frequented by Londoners for recreation, for the commissioners said that it was most important that nothing should be done to countenance its enclosure, and especially so because of its close proximity to the metropolis.

Notwithstanding this remarkable testimony to the public requirements, encroachments upon the forest were allowed to be made with impunity and with an ever-increasing frequency. The result was that by 1848 Epping Forest was reduced to an area of 7,000 acres.

The Crown then took a step which had dire effects. It offered to sell to lords of manors within the forest its forestal rights at the rate of about £5 per acre. The sale of the Crown rights over 3,513 acres followed, and produced £15,793.

Lord Mornington, who had considerable manorial interests, had previously begun to enclose, though bound as its Lord Warden to protect the forest, and by 1851 the open forest had been whittled down to 6,000 acres. This was but a foretaste of what was to follow, for in the next eighteen years the forest, by enclosure, had shrunk to 3,000 acres.

The worst of these encroachments took place in the Manor of Loughton, where the rector and lord of the manor, Mr. Maitland, appropriated in 1866 about 1,300 acres at one scoop. Before doing so he endeavoured to come to terms with the copyholders, who constituted the recognised commoners of his manor. Some were overridden, and other placated by promises of a share of the spoil.

The rights and interests of the general inhabitants were completely ignored, although from time immemorial they had enjoyed the right of lopping the trees for firewood during the winter months, from St. Martin's Day, November 11th, to St. George's Day, April 23rd. " It was," as Lord Eversley observes in his book, " the tradition of the people that this custom had its origin in a grant from Queen Elizabeth, and that it was conditional on their commencing to lop the trees as the clock struck the hour of midnight on the preceding night. They were wont to meet for that purpose at Staples Hill, within the forest, where, after lighting a fire and celebrating the occasion by draughts of beer, they lopped from twelve o'clock till two o'clock, and then returned to their homes. The branches, according to the custom, could not be faggoted in the forest, but were made into heaps 6 ft. high, and were then drawn out of the forest on sledges. In olden times the first load was drawn out by white horses. The wood could only be cut for the use of the inhabitants of the parish.

" It is said that about a century ago the then lord of the manor, wishing to extinguish the custom, invited all his parishioners to a banquet on the eve of St. Martin's Day, and plied them plentifully with liquor, in the hope that midnight would find them in such a condition that they would be unable to perambulate the forest so as to maintain their rights. One man, however

kept his head clear of liquor, and stole from the feast at midnight, perambulated the forest, and exercised his right by lopping some trees, and having done so returned to the feast, where he found his friends still being plied with drink. The lord thereupon, angry at the failure of his scheme, bid them begone with many curses."

On St. Martin's Day in the year 1866, a labourer named Willingale with his two sons determined to exercise their ancient custom of lopping trees for firewood. For this act they were sent to prison for two months with hard labour, and it afterwards transpired that one of the adjudicating magistrates had himself received an allotment from the common over which the Willingales asserted their rights.

At this stage the Commons Society, led by Lord Eversley, intervened, and determined to arouse public opinion upon the subject and to test the validity of the enclosure. For this purpose a guarantee fund of £1,000 was raised by the society, and a suit was commenced in the name of Willingale, claiming on behalf of the inhabitants of Loughton a right to lop the trees for firewood.

The case dragged on, the commoners being gravely hampered by lack of funds to make the necessary, but extremely expensive, researches into the history of the forest. Again and again it almost seemed as though the cause must be abandoned. Again and again, as the minute books of the Commons Preservation Society show, it was only through the splendid generosity of the late Sir T. Fowell Buxton and his brother, Mr. Edward North Buxton, that it was found possible to continue the task. Mr. Buxton's interest in the saving of London's open spaces still continues, and his services to the cause, through the Society and otherwise, have been beyond all praise.

Willingale died in 1870 and his death abated the proceedings. His suit had stopped the destruction of the trees and enabled vitally-important inquiries to be completed, and it was believed that if a commoner possessed of ample means could be found willing to challenge the enclosures there was every prospect of success.

Such a commoner was found in the Corporation of the City of London in respect of an estate of 200 acres at Little Ilford. The Corporation were prevailed upon to take up the cudgels on behalf of the public, and the society's then solicitor, the late Sir Robert Hunter, was associated with the City solicitor in the conduct of a fresh suit.

It was discovered by Sir Robert that, although there were nineteen manors in Epping Forest, the forest itself was one great common, so that the commoners of every one of the nineteen manors had the right of turning out their cattle to graze, without confining them to their particular manor. The Corporation therefore initiated proceedings against sixteen lords of manors.

In the meantime a scheme was put forward in Parliament by the then First Commissioner of Works which proposed that, of the 3,000 acres of open forest still remaining, 2,000 should be given up to the lords of the manor, 400 sold to provide compensation for the commoners, and 600 secured for the recreation and enjoyment of the public. In the light of the subsequent course of events it now seems remarkable that this extraordinary scheme was endorsed by the Government, and might easily have been carried. But the society offered determined opposition to the proposals, which were eventually defeated. A Royal Commission was then granted to inquire into the condition of the forest.

The suit of the City Corporation eventually reached the Court of the Master of the Rolls, Sir George Jessel, and after a most protracted hearing, the arguments alone occupying twenty-three days, it was decided that there was a general right on the part of the commoners to turn their cattle on to the whole of the waste of the forest and that the lords of the manors had no right to make enclosures. This remarkable victory was a complete justification of the policy of the society in rejecting the many attempts which had been made to compromise.

It is unnecessary to recount the doings of the Royal Commission, though they sat for 102 days, save to say that they came to the same conclusions as the Master of the Rolls. They, however, proposed that the lords of manors should be allowed to keep 700 acres which they had wrongfully enclosed, paying rents to form a fund for managing the residue.

Subsequently, the City Corporation bought up the rights of many of the manorial lords, and in 1878 a Government measure was introduced vesting in the Corporation the future control and management of the forest. It directed that all land illegally enclosed, *i.e.*, land enclosed within twenty years of the commencement of the Corporation suit, should be restored, except where it had been already built upon, and it made suitable provisions for the permanent preservation of the forest as an open space. An arbitrator, Lord Hobhouse, was appointed to decide questions with reference to rights and enclosures, and in 1882 his award was presented,

directing the restitution of over 3,000 acres of common land which had been wrongfully enclosed.

The Corporation had spent £33,000 in legal expenses in connection with its great suit. It subsequently added to the forest Wanstead and Higham Parks, and its total capital outlay in buying out the manorial rights and in safeguarding the forest has amounted to not less than £293,252. By its action it has placed the metropolis under a debt of gratitude in part repaid by the knowledge of the enjoyment brought to many thousands by the preservation of London's premier open space.

In the case of other commons the Corporation has also taken noteworthy action, for it acquired, and now holds for the public, Coulsdon Commons, Burnham Beeches and West Wickham Common.

The commons of the manor of Coulsdon are about 347 acres in extent, and were not saved without a bitter fight.

They consist of fine stretches of down land known as Riddlesdown, Kenley Common, Coulsdon Common and Farthingdown, and the lord of the manor, Mr. Byron, after vainly endeavouring to secure their enclosure by an Inclosure Act, strove to enclose parts of the commons and impaired their utility by the wholesale removal of turf. An action brought against Mr. Byron by Messrs. Hall terminated in 1877 in another substantial victory. The enclosures were ordered to be abated and the destruction of the surface of the commons was restrained. The City Corporation subsequently acquired the manorial rights.

The saving of Burnham Beeches was accomplished in a very different manner. This weirdly-beautiful open space is a common of 375 acres, and its ancient groves of beech trees form pictures of sylvan grandeur quite unequalled in any other part of this country. The common had long been included in the estate of the Grenvilles, and for a considerable time arbitrary acts of repression had been bitterly resented by the villagers, who had been accustomed to cut peat in the swampy parts of the common and firewood in its coppices.

In 1879 it was announced that the manor and the common were to be submitted for sale at auction, and expectations were held out that the purchaser would be able to enclose. A deputation of leading members of the Commons Society and the Kyrle Society waited upon a Committee of the City Corporation to urge that they should add to their good work by acquiring Burnham Beeches. It was accordingly bought by Sir Henry Peek and transferred to the Corporation for the sum of £6,000, or less than £20 per acre.

In the meantime the last of the great suits with regard to metropolitan commons had been commenced. This affected the commons of the manor of Banstead. These are known as Banstead Heath, Banstead Down, Park Down and Burgh Heath, which, in the aggregate, comprise over 1,300 acres of breezy downland in North Surrey. The manor in 1873 came into the possession of Sir John Hartopp, who commenced operations by endeavouring to buy the rights of the commoners. To some, money payments were offered by way of compensation for the surrender of their rights, to others the tempting offer was made of the enfranchisement of their holdings free of charge.

It is said that Sir John Hartopp expended in this manner the sum of £18,000, and by 1876 he felt that he had so far progressed with his scheme of getting rid of the commoners' rights as to render safe the enclosure of the commons. He started by erecting houses on Banstead Downs and by enclosing parts of the heath. A local committee was formed, under the direction of the Commons Society, to resist the enclosures, and two of its members, Mr. J. N. Robertson and Mr. H. Fletcher, as freeholders, with two copyholders, agreed to allow their names to be used for the purposes of legal proceedings.

For weary years the fight dragged on, and many preliminary skirmishes occurred before the main action was heard. Moreover, in 1884, Sir John Hartopp's solicitors became insolvent, involving in their ruin the lord of the manor. Two ladies who had been unfortunate enough to advance £31,000 upon the manorial property now took possession of the common under their mortgage deed, and by excessive gravel-digging and turf-paring, threatened to ruin the surface of the commons. The suit was therefore revived as against these ladies.

At length, in 1886, after a lengthy hearing, Mr. Justice Stirling restrained the lord of the manor from enclosing or destroying the pasturage of the commons, but left to a referee complicated questions as to the nature and extent of the rights of common. After researches extending over a further two years, it was abundantly proved that, notwithstanding Sir John Hartopp's efforts to extinguish the rights of common, those that remained were so extensive that, if exercised to their fullest extent, insufficient

pasture existed to supply the needs of the commonable beasts.

In 1889 Mr. Justice Stirling delivered his final judgment in this case in favour of the commoners. This decision was upheld by the Court of Appeal, and subsequently, after a further bitter struggle, the management of the commons was conferred upon a board of conservators by means of a scheme under the Metropolitan Commons Act.

This triumphant victory was not finally achieved until 1893, and the fight had lasted since January 1877.

The result of these many successes was to discourage further attempts at the enclosure of metropolitan commons. It was proved that it was not safe for lords of manors to rely upon the ancient Statute of Merton, on the pretext that they had left open sufficient common for the needs of the freeholders. When put to the test, in every case the defence failed. But while the Statute remained unrepealed or unamended it was a constant menace to every common. Accordingly, in 1893, the society induced the late Lord Thring to introduce a Bill into the Upper House providing that, in future, no enclosure of common land should take place without the consent of the Board of Agriculture, who in giving or withholding their consent were to be bound to take into consideration public as well as private interests. This Bill passed under the title of the Law of Commons Amendment Act, and, it is hoped, has tolled the death-knell of the enclosure movement.

In all these involved proceedings the society was well served by an exceptionably able group of legal advisers. Its first solicitor, Mr. Philip Lawrence, performed yeoman service in the early suits, establishing principles and winning victories in circumstances of great and novel difficulty. His successor, the late Sir Robert Hunter, afterwards Solicitor to the General Post Office, and the chairman of the National Trust, had the conduct of many of the suits, including the Epping Forest litigation, and to his alert mind, amazing knowledge of the law of commons, and persistent effort, much of the success of the society is due. The tradition of these solicitors has been ably maintained by Mr. Percival Birkett, who carried through to victory the complicated Banstead case.

Mitcham Common, another of the large metropolitan open spaces, is 570 acres in extent and has also been the cause of much litigation, both in regard to encroachments and as to the rights of the members of a golf club to play golf over part of it. It was eventually regulated in 1891 under the Metropolitan Commons Act. This Act, indeed, has had most marked results, for it has been employed to safeguard 4,171 acres of common land in and about London.

There still remain about 2,300 acres of unregulated commons in the metropolis, of which the most important are those in the parishes of Epsom and Thames Ditton. Every common ought certainly to be placed under regulation, not only in order to ensure the maintenance of law and order, but also because a regulation scheme ensures the preservation of the common as an open space.

Amongst the many other fine commons to which the machinery of regulation has been applied, are Clapham Common and Peckham Rye. The manorial rights in each of these open spaces are now vested in the London County Council. Clapham Common is 220 acres in extent, and is of great service to cricket, hockey, tennis and football players. Peckham Rye (64 acres) is likewise a popular resort. The claim of the lord of the manor to enclose this common was strongly contested before the Select Committee in 1865, the dispute being subsequently settled by the purchase of the manorial rights.

An interesting circumstance in connection with the commons and parks of London is the extensive use to which they have lately been put for military exercises and evolutions. It is not too much to say that the protection of these open spaces and rural commons, too, has of late, been the means of saving the country vast sums of money which must otherwise have been spent in providing training grounds for troops. Villagers have cheerfully acquiesced in the temporary appropriation of their greens and commons, confident that, when the national exigencies permit, they will be restored again to popular use.

It must not be thought that because the work of the society during the last fifty years has been buoyed up by so much success, nothing further remains to be done. The history of the protection of rural commons is another story, and results have been achieved in the country as remarkable in their way as those which have followed the efforts of the society in and about London. An entirely new spirit prevails, for the Inclosure Commissioners, whose object it was to facilitate the enclosure of commons, have ceased to exist. Their place has been taken by the Board of Agriculture, which is

bound to have regard to the public rather than private interests. It is no less than their due to say that the permanent officials of the Board have earned the thanks of the community for the enlightened way in which their duties are now performed.

Nevertheless, signs are not wanting that some persons unacquainted with the past history of commons, with the economic ruin that their enclosure often brought about, and with their value to the public as open spaces, would exploit the country's present difficulties in the matter of food supply by urging that every inch of common land should be enclosed and cultivated. They overlook the fact that most of the commons which succeeded in escaping the widespread net of the enclosure movement, owed their escape to the circumstance that their soil is of too poor a quality to render cultivation profitable. They overlook, too, the truth expressed in those wise words, "Man shall not live by bread alone." Even if it does not grow an ear of corn, a common is a national asset. In America, vast reserves of land have been set apart for the use of the community. Our commons are natural reserves which it would be folly to sacrifice upon the altar of utilitarianism while millions of acres of enclosed land lie idle in a productive sense. Then, too, undesirable schemes of afforestation require to be watched; illegal enclosures are still constantly taking place, and within the last few months it has been necessary to fight for the modification of arterial road schemes, one of which as originally proposed would have gravely injured Epping Forest.

Fifty years ago, when the small band of seven men, led by Lord Eversley, determined to fight against the absorption of metropolitan commons, they could scarcely have dared to look for the startling results to which their action was destined to lead. The society formed by them has always had to struggle against financial difficulties, more especially as it was soon found necessary to increase its scope so that it might safeguard rural as well as metropolitan commons, and protect footpaths and other highways as well. There were in 1865 about 16,320 acres of common land within the Metropolitan Police District. Much of this had been fenced in, and lords of the manors claimed the right to enclose the whole without regard to the wishes of the community.

Thanks to the crusade inaugurated by the society, of that great area it is probable that less than 200 acres have passed into private hands. Other portions, totalling perhaps a rather larger acreage, have been taken for waterworks and other semi-public purposes. Of the amount remaining, about 14,000 acres have been definitely secured for ever by the many suits fought under the direction of the society, or by purchase or regulation, and about 2,300 acres, though available for public use, remain to be dealt with.

The total area of open spaces to which the public have access, including all commons, and royal parks—such as those at Richmond and Bushey—in the Metropolitan Police District is approximately 25,431 acres, of which 15,900 acres are or were common lands. If brought together into one large tract the open spaces of London would occupy an area of about forty square miles, or if extended into a line they would form a continuous strip over three-quarters of a mile broad, stretching from London to Brighton.

Yet no one would assert that London is too well equipped with facilities for recreation when it is realised that there is but one acre of open space in London proper for every 678 inhabitants, while in Southwark the proportion is far less, for it is only one acre for every 14,499 persons.

London has been fortunate in possessing, beyond the Commons Society, other open space organisations such as the Metropolitan Public Gardens Association, which has done so much to preserve square gardens and disused burial grounds, the Kyrle Society, and the National Trust. These four societies have been closely associated in formulating or assisting nearly every London open space scheme launched during the past thirty years.

The whole movement, too, has been greatly stimulated by the ardent band of champions of public rights who gathered around Lord Eversley, sinking political and other convictions in the one aim of saving the people's commons. Many have been already alluded to; amongst others who should be named are the late Professor Fawcett, Mr. John Stuart Mill, Sir Charles Dilke, Mr. C. Buxton, Mr. W. H. Smith, Professor Huxley, Mr. Samuel Morley, the Duke of Westminster, Dean Stanley, Miss Octavia Hill, Lord Bryce, Mr. Edward Bond, Sir John Brunner, Mr. J. F. L. Brunner, M.P., Mr. Briscoe Eyre, Sir Frederick Pollock, and our chairman of to-day, Lord Farrer. Many others could be added to this short list.

Most of the early members have passed away, but not before seeing generally accepted the great principles they set before themselves, and not before knowing that the bulk of the

common lands of London had been placed beyond the possibility of successful attack. Though they have gone to their rest, the ceaseless vigil of the people's watch-dog, as the society is known in Parliament, goes on; for the members are resolved to be ready to sound the alarm when fresh invasions of public rights are threatened, and ready too, if need be, to fight again in defence of the national heritage—our common lands, for

"There the turf
Smells fresh, and, rich in odoriferous herbs,
. . . regales the sense
With luxury of unexpected sweets."

DISCUSSION.

THE CHAIRMAN (Lord Farrer), in inviting the meeting to discuss the paper, desired to say how much he appreciated Mr. Chubb as secretary of an unobtrusive body which had done the largest amount of work with the smallest amount of money of any society he had come across. He might mention that the author was not Mr. Chubb of Salisbury, who had bought Stonehenge and charged the public for admission, but Mr. Chubb of the Commons and Footpaths Preservation Society. He did not think that anybody who had not been daily brought into contact with Mr. Chubb realised the great work which he did, day in and day out, in endeavouring to protect the interests of the public. It might fairly be asked what was the reason of the success of the movement—for successful it had unquestionably been. In thinking it over, it seemed to him that it was because it was a form of what might be termed sane State Socialism, that was to say, a form of public enjoyment against mere private rapacity. It was very interesting to go back, as Mr. Chubb had done, to 1265, and notice that human nature had not changed very much in the seven centuries that had elapsed. In those days, and possibly now, there were land-grabbers in Europe. The Norman kings loved hunting; to-day people were more cultivated and were fond of Nature in other aspects, and the Commons Preservation Society undoubtedly tried to preserve those aspects to the inhabitants of towns. He had been very much interested lately, in going through the camp on Witlay Common, to notice that that lovely common had been converted by the War Office into a most hideous waste, and to notice that, although the people at the head of affairs had put up a large gas factory, the soldiers were cultivating small gardens around their huts. The lord of the manor, Lord Midleton, he believed, had an agreement to the effect that at the end of the war the common was to be restored to its original condition, but it would take some little time to do that. There was one other branch of work which Mr. Chubb was interested in, namely, the preservation of footpaths. His (the speaker's) view was that the English law was very favourable to the public as compared with the laws of other countries with which he was acquainted, as it enabled the people of this country to enjoy commons in a way that was not possible in countries under the Napoleonic Code. He himself went back to the old Shakespearean tag—

"Jog on, jog on, the footpath way
And merrily hent the stile-a:
Your merry heart goes all the day,
Your sad tires in a mile-a!"

MR. WALTER F. REID said he had had the pleasure of knowing Mr. Chubb for many years, and knew that he had not only done good work with regard to the preservation of commons and footpaths, but in other directions also. He had been interested in the remark made with regard to the growth of juniper bushes near London, because Mr. Chubb happened to be the Secretary of the Coal Smoke Abatement Society, and the efforts of that society had materially improved the atmosphere. A great deal of the success was due to the energy and tact of Mr. Chubb. He had never heard a paper which was so clear, definite and eloquent, and he believed it would be a work of reference on the subject of commons.

MR. JAMES ELLIS said that when the great services Mr. Chubb had rendered to the public were known, he would receive much more recognition and the receipts of the society would be greatly increased. For many years he himself had been personally familiar with the commons that had been saved to the public, and he knew that Lord Eversley and Mr. Chubb had rendered services beyond all price, and were amongst the few men who enjoyed the confidence of men of all shades of politics, and stood high in the esteem of everyone acquainted with their work. Mr. Chubb was an authority on the rights of the public, and was often called in by agreement between parties to act as arbitrator, and his judgment was trusted and accepted and treated as final.

On the motion of the CHAIRMAN a hearty vote of thanks was accorded to Mr. Chubb for his interesting paper.

MR. CHUBB, in responding, said he greatly esteemed the kind words which had been spoken with regard to him. It was a genuine pleasure to be the secretary of an organisation such as the Commons Preservation Society, with regard to which he felt it possible to put his whole heart into the work. It had been a very great pleasure to him to prepare the paper, and endeavour to tell the story of what had been done by members of the society.

CORRESPONDENCE.

THE VALUE OF BIRDS TO MAN.

In the issue of your *Journal* for October 29th I see a letter from Mr. James Buckland in reply to mine which appeared in the issue of August 20th.

All bird lovers in Jamaica fully appreciate Mr. Buckland's efforts for the better preservation of bird-life, but I for one cannot think that the cause is helped by statements unsupported by evidence, by theories that seem almost fanciful, and by charges of deadness and slumber, which are ill-deserved.

Mr. Buckland says: "It is not at all certain that the importation of infected cattle was the agency by which the tick pest was first introduced into the island." The outcry against ticks certainly arose after the first importation. There were ticks before, but no tick plague.

Mr. Buckland expresses the opinion that the Texas fever tick was brought to Jamaica by the wind. If he had seen the ticks on the stock imported from the regions where Texas fever is a well-known plague he would hardly have felt it necessary to credit them with so fanciful a flight. He quotes the report of the Twenty-first Expedition of the Liverpool School of Tropical Medicine for his own purpose, but he carefully abstains from quoting it where it says: "A small proportion may be wind-borne, though it is doubtful if such an agency would carry 'grass lice' to any great distance from an infected area."

Mr. Buckland says: "The number of bird skins from Jamaica which poured into Europe and into New York City when the slaughter was at its height is truly appalling. It is not easy for me to recall to memory the hundreds of thousands I have seen in England, France, Holland, and Germany, without the feeling of indignation I experienced at the time again rising within me." Can he give any proof that these bird skins came from Jamaica? There is no proof to be obtained in Jamaica. There has not been any considerable export of bird skins from Jamaica within living knowledge. He says: "Whole species have been wiped out of existence, while of those that were most abundant only a pitiful remnant remain." Which species? Of the 194 birds of Jamaica enumerated by Alfred and Edward Newton in the "Handbook of Jamaica for 1881" the following notes were made by the late Dr. Sclater when he published a revision of the list in the "Handbook" for 1910:—

The long-nostrilled night-jar (*Siphonorhis americanus*) is marked as "very rare and possibly now extinct"; the Jamaica macaw (*Ara gossii*) is "almost if not quite extinct"; the blue dove (*Geotrygon cristata*) is "said to be becoming extinct since the introduction of the mongoose"; the northern courlan (*Aramus giganteus*) is "now nearly extinct"; the Blue Mountain duck (*Oestrelata jamaicensis*) is "supposed to be now extinct." Of these none but the macaw could possibly have tempted "gunners" as "birds which carried marketable feathers." It cannot be said that the insect-eating small bird is as a rule so beautiful as to appeal to the milliner.

Mr. Buckland states that "native breeds of cattle enjoy an almost total immunity from the plague of tick-fever, while imported cattle suffer terribly." By "native" he possibly means creole cattle. These suffer far more than imported Indian cattle, which are practically immune.

Mr. Buckland says that "the Birds and Fishes Protection Law is a sham and fills the mouth of the gunner with laughter." Practically the only "gunners" in the island are those who shoot in due season the various forms of pigeons for the table. The cost of the gun licence and ammunition certainly act strongly against the wanton destruction of birds by means of firearms by the ignorant classes.

Mr. Buckland considers that it is easy "for the bird under natural conditions to keep the tick in check." There are few in Jamaica who will agree with him, if natural conditions include the keeping of cattle; for the tick is a favourite food of but a limited number of birds, and the ticks were certainly gaining on their natural enemies before the introduction of the mongoose. Mr. Buckland mentions that "seventy-four adult ticks, all females in an engorged condition, have been taken from the stomach of a bird after its early morning meal." He does not state that the bird was (as given by the authority from which he gleaned his information) a tinkling grackle, which is protected by law.

Mr. Buckland says: "Mr. Cundall states that the island of Jamaica is remarkably suitable for the breeding of cattle," and says this is untrue. I quoted the words of the Director of Agriculture, whom Mr. Buckland had quoted in his previous paragraph as saying that "experience teaches us that there is no such thing as immunity for an imported dairy cow in Jamaica, and we must expect all our imported cows to succumb to tick-fever sooner or later." The two remarks are compatible. One might as well say that because Europeans on first coming to the tropics are more liable to disease than old stagers that the tropics are not suitable as a home for Europeans and their creole offspring!

Apart from bird-lovers there are those who are naturally deeply concerned to preserve all insect-eating birds, useful to man, directly or indirectly, through their value to the agriculturist. But to enlist the aid of the people, especially the peasant employed in agriculture here, and to educate the youth of the country out of his ingrained propensity toward the destruction of birds by means of stones, springs, and catapults, one must use arguments based on well-established facts and not on fanciful or theoretical beliefs, at which he will softly smile. The paroquet, which has been lately removed from the totally protected to the partially protected schedule in the law, is most destructive to oranges and other fruit, more still

to the poor man's corn, and has increased enormously in the thirty years of "protected" life, and the hawks not only prey on poultry and domestic pigeons, but are the chief foes of the small insect-eating birds, far more so than the imaginary "gunners."

Mr. Buckland appears to be obsessed with the idea that the bird-life of Jamaica is being destroyed by the hunter for birds which carry marketable feathers, and seems to base all his arguments on a statement in proof of which he offers no evidence, and which, with full local knowledge, I assure him is incorrect. He is equally incorrect in the gloomy view he takes of the results of the present efforts of stock-owners in combating the tick pest. The results of the dipping and spraying which very many pen-keepers now diligently practise are just as encouraging as the results of similar efforts in the many other countries where they have become necessary.

FRANK CUNDALL.

Kingston, Jamaica.
December 28th, 1915.

NOTES ON BOOKS.

HISTORIC JAMAICA. By Frank Cundall, F.S.A., Institute of Jamaica, and West Indian Committee. London, 1915.

The island is fortunate in having so earnest and persevering an archæologist as the Secretary of the Institute of Jamaica to undertake the duty of recording the plans and objects of historical interest which it possesses. The history of Jamaica appears to commence in 1655, when it was taken from the Spaniards by an expedition sent out by Cromwell. Before that date little is known. Research and excavation have discovered almost nothing about the inhabitants of the island before its discovery by Columbus, and "with regard to the Spanish occupation of the island, both history and archæology are almost as scantily supplied as in the case of the Arawâks."

It is, therefore, only as an English colony that Jamaica has a history. Her prehistoric ages extend down to the middle of the seventeenth century. For the two-and-a-half centuries of recognised existence the records are complete enough, and the materials for writing its political history are sufficient. The list of Governors is complete, from General Doyley in 1661 to Sir W. H. Manning in 1913. The changes in the methods of administration are all set out in the authorities where such matters are recorded, while the naval victories, which are the chief glory of West Indian history, have been fully and worthily dealt with by our historians.

It is not, however, of such high matters that the present volume deals, but with the actual existing objects of historical interest which have survived the disintegrating influence of a tropical climate and the destructive efforts of the ignorant destroyer, the renovator and the religious reformer.

In 1900 Mr. Cundall published an account of some of the more important historic sites in Jamaica. In 1908 the West Indian Committee, moved by the appointment of the Royal Commission on Historical Monuments, appealed to the Colonial Office for similar action in the West Indian Colonies, and the result was that the suggestions of the committee were "recommended for the consideration" of the Governors of those colonies. This non-committal sort of recommendation had its effect in Jamaica, for the result was that Mr. Cundall, "at the request of the Governor," "undertook to prepare a list, parish by parish, of historic sites, buildings and monuments." This list was published officially, and formed part of a Report presented to Parliament three years ago. It also formed the groundwork of a series of articles on the subject, and these again have been elaborated into the present book.

The record is considerable, and appears to be complete, as indeed might be expected from so painstaking a student as its author. It is arranged under the fifteen parishes into which the island is divided, each parish being allotted a chapter to itself.

There is also an historical introduction dealing with the original inhabitants, the Arawâks, the Spanish occupation, the English possession, the physical features of the island, its products, etc. Amongst other matters may be noted a good account of the Botanic Gardens of Jamaica, since it was due to the efforts of the Society of Arts, from 1760 onwards, that the first attempt was made to establish in the West Indies "gardens or nurseries for the making experiments in raising such rare and useful plants as are not the spontaneous growth of the kingdom or of the said colonies."

THE ARCHITECTURE OF ANCIENT EGYPT. By Edward Bell, M.A., F.S.A. London: G. Bell & Sons, Ltd. 6s. net.

Recent research has thrown a great deal of fresh light on the history of architecture in Egypt, and though much has been written in special books and papers on the various points dealt with in these researches, this would seem to be the first attempt to bring together the fresh information in a connected and easily accessible form.

One of the facts which Mr. Bell does well to emphasize, is the great length of the period over which the development of Egyptian architecture extended. Owing to the way in which the subject is frequently treated in text-books dealing with the history of architecture generally, the casual student is apt to gain the impression that the so-called "orders" were contemporaneous, and that the Egyptian

period was more or less of the same length as the classic period. It is, of course, impossible to trace the history of the art to its very beginnings, but in his chapter on prehistoric and dynastic Egypt the author makes it clear at once that Egyptian architecture was flourishing in the Old Kingdom in the fourth millennium B.C., and that its period extended over three or four thousand years. It is curious that in all this length of time there was so little tendency towards progress; for although the various "orders" had their own features, the main characteristics of Egyptian architecture remained peculiarly distinctive and unaltered. This permanent nature of the art is generally recognised as being due to the conservative influence of the priesthood, and it is a striking proof of their power that they were able to persuade even foreign conquerors to adopt the native superstitions and religions.

The book is copiously illustrated with photographs, drawings, maps and plans, which add very materially to its interest and value.

THE TELEPHONE AND TELEPHONE EXCHANGES. By J. E. Kingsbury, M.I.E.E. London: Longmans, Green & Co. pp. 558. 12*s*. 6*d*.

This is a very complete history of the origin, growth, and development of the telephone from its inception in the work of Graham Bell and his father on "Visible Speech" down to its elaboration in the modern exchange. Practically the book divides itself into two parts, the first being more or less the early history, and the second half an account of the existing system, with details of the arrangements of exchanges with all their complicated organisation and elaborate instruments.

It is not generally known that the word "telephone" anticipated the existence of the instrument to which it is now solely applied. Various devices for transmitting sounds such as speaking-trumpets were called telephones. Mr. Kingsbury mentions an apparatus for conveying signals during foggy weather by means of compressed air forced through trumpets, which is described under the name of telephone in the "Year Book of Facts in Science and Art" for 1845, the inventor being one Captain John Taylor. Murray's Dictionary quotes from the *Times* of the previous year a still earlier reference to this apparatus. From the same authority it appears that the word "telephone" was first applied to a system of signalling devised by Sudro in 1828 and described in Wilson's "New Musical Dictionary" (1834).

Mr. Kingsbury also refers to the gutta-percha telephone exhibited by Francis Whishaw at the 1851 Exhibition. This he thinks was a speaking-trumpet, but it was really an acoustic reflector. Whishaw was not, as Mr. Kingsbury says, a manufacturer, but an engineer, and for some years up to 1845 he was secretary of the Society of Arts. In the year 1845 he read a paper before the Society on the "Uses of Gutta Percha," for the discovery of which the Society's Gold Medal was awarded a few months later to Dr. William Montgomerie. Whishaw realised the value of the material, and he then showed the Society the specimens which Montgomerie had sent from Singapore, and some articles he had himself made from the material, including pieces of pipe, a lathe-band, and some impressions of medals. As nothing is said about a telephone, it is most probable that this device was constructed later. It was shown at a soirée of the Royal Society in the summer of 1849, and really consisted of two large concave reflectors fixed opposite to one another at a suitable distance, so that a message spoken into one was reflected into the other. It was stated that a whisper could be heard at a distance of 40 ft., and that the inventor anticipated that a loudly-spoken tone would be heard at a distance of a quarter of a mile. Whishaw also made speaking-tubes of gutta-percha, but there is no available evidence to show that he claimed to be the inventor of the speaking-tube.

Mr. Kingsbury also refers to Wheatstone's device for carrying musical sounds from one room to another by the use of a solid rod, now a common lecture experiment, and says that Tyndall utilised the illustration in the course of a series of lectures on Sound at the Society of Arts. As a matter of fact, these lectures, though they were mentioned in the *Journal* at the time, had nothing to do with this Society. They were really delivered at the Royal Institution, and were afterwards elaborated into Tyndall's well-known book on Sound. The apparatus formed the basis of Professor Pepper's "Telephone Concerts" at the Polytechnic.

These introductory matters have their interest for those who care for such things, but they are the mere fringe of the subject. The real value of the book is that it provides a very full and apparently accurate account of Professor Bell's researches and experiments which ended in producing the electric telephone as we now know it, with the exception, of course, of the important addition of Professor Hughes's microphone to the telephone transmitter. Due credit is given to Philipp Reis for his early work, and to Professor Hughes and others who co-operated in the development of the instrument. Mr. Kingsbury has the advantage of writing about matters within his own knowledge, and within that of his contemporaries. The general objection to contemporary history, that the point of view is too near, and involves an absence of correct perspective, hardly applies to technical history, in which correct statement is all-important and picturesque treatment is non-essential. If the amount of detail is somewhat excessive, this may well be forgiven in consideration of the fulness and accuracy of the information.

The latter and more technical portion of the book is intended for specialists, and to their notice it may be recommended, for they will find not only full information about the organisation of telephone exchanges in this country, but also full details of those in the United States, which are admittedly ahead of any in this country. According to evidence quoted by Mr. Kingsbury, it is not an uncommon thing for an operator to make 200 connections per hour—that is to say, she will answer the call, get the person called for, and put them together. As many as 222 connections have been counted. Whether a similar speed has ever been attained in this country does not appear to be stated. At all events, it is a record of a remarkable fact, and illustrates the female capacity for endurance.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m. :—

January 26.—J. Arthur Hutton, Chairman of the British Cotton-Growing Association, "The Effect of the War on Cotton-Growing in the British Empire." Sir Daniel Morris, K.C.M.G., D.C.L., D.Sc., will preside.

February 2. — The Hon. Lady Parsons, "Women's Work during and after the War." Dugald Clerk, D.Sc., F.R.S., Chairman of the Council, will preside.

February 9.—Professor J. A. Fleming, M.A., D.Sc., F.R.S., "The Organisation of Scientific Research." Dugald Clerk, D.Sc., F.R.S., Chairman of the Council, will preside.

February 16. — S. Charles Phillips, M.S.C.I., "Paper Supplies as affected by the War." Lord Burnham will preside.

February 23.—Miss H. B. Hanson, M.D., B.S., D.P.H., "Serbia as seen by a Red Cross Worker."

March 1.—Charles Delchevalerie, "Belgian Literature."

March 8.—Charles R. Darling, A.R.C.Sc.I., F.I.C., "Optical Appliances in Warfare."

Indian Section.

February 17.—C. A. Kincaid, C.V.O., Indian Civil Service (author of "Deccan Nursery Tales," "The Indian Heroes," "The Tale of a Tulsi Plant," etc.), "The Saints of Pandharpur: the Dawn of the Maratha Power." Lieut.-Colonel Sir David W. K. Barr, K.C.S.I., will preside.

March 16.—Professor Wyndham R. Dunstan, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India."

Dates to be hereafter announced :—

R. W. Seton-Watson, D.Litt., "The Balkan Problem."

Rev. P. H. Ditchfield, "The England of Shakespeare."

W. A. Craigie, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

Victor Horta, Directeur de l'Académie Royale des Beaux-Arts de la Ville de Bruxelles, "Belgian Architecture."

Professor T. G. Masaryk, "The Slavonic Peoples."

G. P. Baker, "Hindu Hand-painted Calicoes of the Seventeenth and Eighteenth Centuries, and their Influence on the Tinctorial Arts of Europe."

Edward Percy Stebbing, F.L.S., F.R.G.S., Head of the Department of Forestry, University of Edinburgh, "Forestry and the War."

Sir Daniel Morris, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland."

James MacKenna, M.A., I.C.S. (Deputy Commissioner, Myaungmya, Burma, and designated Agricultural Adviser to the Government of India), "Scientific Agriculture in India."

Indian Section.

Thursday afternoons at 4.30 p.m. :—

April 6, May 18.

Colonial Section.

Tuesday afternoons, at 4.30 p.m. :—

February 1, March 7, May 2.

Cantor Lectures.

Monday afternoons at 4.30 p.m. :—

J. Erskine-Murray, D.Sc., F.R.S.E., M.I.E.E., "Vibrations, Waves, and Resonance." Four Lectures.

May 1, 8, 15, 22.

Fothergill Lectures.

Monday afternoons, at 4.30 p.m. :—

Rev. Dr. Herbert West, D.D., A.R.I.B.A. (author of "Gothic Architecture in England and France"), "National and Historic Buildings

in the War Zone: their Beauty and their Ruin." Three Lectures.

Syllabus.

LECTURE I.—FEBRUARY 7.—*Belgian Architecture and History.* Belgium a land of cities—What makes a city (Gen. xi. 4)—Tower—Church—Communal Hall—Belgian civil architecture, commercial —Cloth Halls before Town Halls—Churches borrowed, but splendid furniture given by Trade Guilds. Ypres typical — Tournai. Rhenish. Source of Noyon—Soissons. St. Remi—French efforts to annex Flanders—The Matins of Bruges —Battle of the Spurs. Courtrai—Rivalry of Ghent and Bruges—Edward III. and J. van Artevelde—Sluys—Coucy. Pierrefonds—Mediæval sieges—Philip van Artevelde, Roosebek. Suzerainty of Burgundy—Charles the Rash and Louis XI. Dinant—Sack of Liége. Mary of Burgundy. Arras—Lierre. Charles V. and Philip II. Egmont and Horn—Louvain—Malines—Antwerp—Louis XIV. and William III. Namur. Bombardment of Brussels.

LECTURE II.—FEBRUARY 14.—*Gothic Architecture, French and English.* The French Cathedral, a Great Hall, the centre of the city's life. The English Cathedral a Monastic Missionary settlement, independent of the city. The problem of Mediæval Architecture, to reproduce Roman vaulting—Solved by permanent stone centrings (diagonal ribs) under the intersections of a groined vault (Vezelay, Durham, St. Denis, Sens). Buttresses necessary (Chartres, Amiens, Beauvais). The walls become screens of glass. Inside—Columns replaced by vaulting ribs running down to the ground (Notre Dame—N. D. de l'Épine, Abbeville). Contrast of French and English plans (Notre Dame and Salisbury). In the English Cathedral, horizontal, not vertical perspective sought. Beauty of clustered columns. Purbeck causes deep mouldings. Multiplication of vaulting ribs. Lierne and fan vaulting—Flamboyant and perpendicular—English and French façades—The French Cathedral is the expression of the National ideal; the English, of the National history.

LECTURE III.—FEBRUARY 21.—*French Mediæval Sculpture.* Christian art that of a new-born society rising amidst a dying civilisation—Provençal sculpture, Arles, etc., decadent—Burgundian, full of life and imagination; but Classical influence traceable all through (Vezelay, Autun, Auxerre)—XIIth Century (Avallon, Bourges, N. and S. doors, Chartres, W. front). Elongation of statues, architectural not ignorant—Individual types, elaborate detail. The sculpture scheme of a XIIIth Century cathedral (Laon, Notre Dame, Amiens, Reims). The Judgment door (Autun, Notre Dame, Amiens, Rampillon, Reims, St. Maclou)—The Virgin's door—Local Saints and legends (St. John Baptist, Rouen; St. Stephen, St. Théophile, Paris; St. Thomas, Semur; St. Nicaise, Reims)—The Arts, Virtues and Vices—The Months and Daily Life (Paris, Amiens, Rouen)—Statuary (St. Stephen, Sens—The Virgin, Paris—Chartres, N. and S. porches)—Reims, W. portals—Figures of Christ (Chartres, Amiens, Reims, Troyes, Solesmes).

The lectures will be illustrated by lantern-slides.

EDWARD A. REEVES, F.R.A.S., Map Curator, Royal Geographical Society, "Surveying." Three Lectures.

March 27, April 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 24...Farmers' Club, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Mr. W. J. Malden, "Labour-saving Implements and Machinery."

East India Association, Caxton Hall, Westminster, S.W., 4.15 p.m. Lady Muir-Mackenzie, "Indian Women and National Well-being."

Geographical Society, Burlington-gardens, W., 8.30 p.m. Professor J. W. Gregory, "Cyrenaica."

TUESDAY, JANUARY 25...Royal Institution, Albemarle-street, W., 3 p.m. Professor C. S. Sherrington, "The Physiology of Anger and Fear." (Lecture II.)

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Discussion on Mr. F. W. Carter's paper, "The Electric Locomotive."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Dr. C. A. Swan, "Round the Mediterranean and the Near East."

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 4 p.m.

Electrical Engineers, Institution of (Local Section), 17, Albert-square, Manchester, 7.30 p.m. Paper on "Printing Telegraphs."

WEDNESDAY, JANUARY 26...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. J. A. Hutton, "The Effect of the War on Cotton-Growing in the British Empire."

University of London, King's College, Strand, W.C., 5.15 p.m. Professor F. J. C. Hearnshaw, "The War and the Baltic."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5 p.m. Mr. A. C. Benson, "The Letters of Mary Sibylla Holland."

THURSDAY, JANUARY 27...Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Professor W. A. Bone, "The Utilisation of Energy from Coal: Fuel Economy from a National Standpoint." (Lecture II.)

China Society, Caxton Hall, Westminster, S.W., 3.30 p.m. Mr. S. G. Cheng, "The Chinese as a Warrior in the Light of History."

FRIDAY, JANUARY 28...Royal Institution, Albemarle-street, W., 5.30 p.m. Dr. L. Hill, "The Science of Clothing and the Prevention of Trench Feet."

Physical Society, Imperial College of Science, South Kensington, S.W. (Guthrie Lecture.) Mr. W. B. Hardy, "Some Problems of Living Matter."

Engineers and Shipbuilders, North-East Coast Institution of, Newcastle-on-Tyne, 7.30 p.m.

SATURDAY, JANUARY 29...Royal Institution, Albemarle-street, W., 3 p.m. Mr. C. J. Holmes, "Raphael and Michelangelo." (Lecture II.)

Journal of the Royal Society of Arts.

No. 3,297. VOL. LXIV.

FRIDAY, JANUARY 28, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, FEBRUARY 2nd, 4.30 p.m. (Ordinary Meeting.) THE HON. LADY PARSONS, "Women's Work during and after the War." DUGALD CLERK, D.Sc., F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

PRESENTATION OF THE ALBERT MEDAL TO PROFESSOR SIR JOSEPH JOHN THOMSON.

At the last meeting of the Council, on Monday afternoon, the 24th inst., Dr. Dugald Clerk, F.R.S., Chairman of the Council, on behalf of H.R.H. the Duke of Connaught and Strathearn, K.G., President of the Society, presented the Society's Albert Medal to Professor Sir Joseph John Thomson, O.M., D.Sc., LL.D., F.R.S., "for his researches in physics and chemistry, and their application to the advancement of Arts, Manufactures, and Commerce."

In making the presentation, Dr. Clerk said :—

"Sir J. J. Thomson is the successor of Clerk-Maxwell, in that he deduced the physical consequences of Clerk-Maxwell's electro-magnetic theory and studied the numerous phenomena of high-frequency electric oscillations. His many investigations on these matters have proved of the greatest value to the electricians who developed the practice of modern wireless telegraphy. Among his important contributions to such knowledge may be mentioned his discovery of the change in the dielectric strength of the atmosphere and other bodies for high-frequency oscillations, also the variations with changing atmospheric density.

"His more abstract work on the atom and molecule is equally useful in that it renders possible a reasonable theory of the nature of matter and gravitation. Newton discovered the law of gravitational attraction; it remained for Sir J. J. Thomson to throw light upon the various theories of this most mysterious of phenomena.

"His brilliant work has also industrial possibilities in the region of motive power; but altogether apart from this, the new knowledge of the nature of the atom and molecule mark an epoch of intellectual advance of the highest importance to mankind."

In addition to the Chairman, the following members of the Council were present:— Sir Steuart Colvin Bayley, G.C.S.I., C.I.E. (Vice-President), Alan S. Cole, C.B., William Henry Davison, M.A. (Treasurer). Sir Steyning William Edgerley, K.C.S.I., K.C.V.O., C.I.E., Peter Macintyre Evans, M.A., Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc. (Vice-President), Major Percy A. MacMahon, R.A., LL.D., D.Sc., F.R.S., Hon. Richard Clere Parsons, M.A., Sir Robert W. Perks, Bt., Sir Boverton Redwood, Bt., D.Sc., F.R.S.E., Lord Sanderson, G.C.B., K.C.M.G. (Vice-President), John Slater, F.R.I.B.A., Alan A. Campbell Swinton, F.R.S., and Professor J. M. Thomson, LL.D., F.R.S. (Vice-President).

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1*s.* 6*d.* each, on application to the Secretary.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

SEVENTH ORDINARY MEETING.

Wednesday, January 26th, 1916; SIR DANIEL MORRIS, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Bird, Captain Clarence A., R.E., 42, Fordhook-avenue, Ealing Common, W.

Crowther, Charles, 63, Yamamoto-dori 4 Chome, Kobe, Japan.

The following candidates were balloted for and duly elected Fellows of the Society:—

Haddon, Walter, 132, Salisbury-square, E.C.

Henderson, Lucius J., 10, Fauenil-place, New Rochelle, New York, U.S.A.

Howell, Hon. Clark, Atlanta, Georgia, U.S.A.

Lal, Lala Mohan, B.A., Gulshan Villa, Simla, India.

Phillips, J. S. M., Merchant's Bank, Pittsburgh, Pennsylvania, U.S.A.

Robbins, Rowland Richard, J.P., Holly Croft, Sipson, Middlesex.

Wooldridge, Charles L., Fulton Building, Pittsburgh, Pennsylvania, U.S.A.

The paper read was—

THE EFFECTS OF THE WAR ON COTTON-GROWING IN THE BRITISH EMPIRE.

By J. ARTHUR HUTTON,
Chairman of the Council of the British Cotton-Growing Association.

There could hardly be a more appropriate time for considering how the industry of cotton-growing, which has been established in new fields within the Empire, has been affected by the war, and also, which is perhaps more important, what are the prospects for the future. An immense amount of time, energy and money has been devoted to the cause during the last dozen years, and it would be a calamity if all these efforts were to be wasted and if this new industry were to disappear entirely, or even to come to a standstill. Before, however, considering this problem, I propose, for the benefit of those who are not acquainted with the details of our work, to give a short account of the causes which led to the formation of the British Cotton-Growing Association, and of the work which we have so far been able to carry out.

THE ORIGIN OF THE MOVEMENT.

During the five years ending in 1895 the cotton crop of the United States averaged about 8,300,000 bales—with fluctuations between 7½ and 10 million bales. In the following five years the average production rose to about 9,500,000 bales, with a minimum of 7 and a maximum of 11¼ million bales. This increase of 1,200,000 bales was, however, accompanied by increased consumption in America and more particularly in the Southern States. The consumption rose from 2,600,000 to 3,200,000 bales, so that the States themselves used up fully half of the increased production, and whereas they formerly used 31 per cent. of the total crop, their consumption rose to 34 per cent. The result was that there was some considerable shortage in the available supply of the raw material for the rest of the world. In the year 1900 the total crop amounted to only 9,422,000 bales, with the consequence that many of the mills in Lancashire had to run short time. I need hardly dwell on the sufferings which were caused, and the monetary losses which followed; but I must insist on this point, that in difficulties of this sort labour always suffers more than capital. Spinners, manufacturers, and merchants can frequently make up previous losses when prosperous times again return, but time once lost by the operatives is gone for ever.

In January 1901, at the annual dinner of the Oldham Chamber of Commerce, Mr. Benjamin Crapper, who is one of the most active members of our Council, drew attention to the dangerous position of the Lancashire cotton industry, owing to the fact that it was dependent on the United States for the bulk of its supplies of the raw material, and therefore was at the mercy of the vagaries of the weather in one particular part of the world. He also drew attention to the obvious fact that the only way in which the calamity of a short crop could be avoided in the future was by the establishment of cotton-growing in all parts of the world. If the basis of supply could be broadened, and if cotton could be grown in quantity in Africa and other countries as well as in India, Egypt and the United States, one could regard with comparative equanimity the failure of the crop in any particular country, for in all probability this would be counterbalanced by more favourable climatic conditions elsewhere. If this could be done successfully the market would no longer be at the mercy of ruthless speculators, who, whenever the conditions were favourable,

would "corner" the market and force prices up as much as possible, regardless of the sufferings they might inflict on the hard-working operatives. We all realise that a shortage of wheat and dear bread is a calamity for the working-classes, and more especially for those who have a difficulty in making both ends meet. It is, perhaps, not so generally realised that to Lancashire, and indeed to the cotton trade of the whole world, cotton is equally important. It is a common saying that cotton is Lancashire's "bread and butter." I should also point out that many other people are also seriously affected, for cotton is the cheapest of all textile materials, and the poorest people in the world use no other clothing than cotton. If, therefore, the price of cotton rises in consequence of short supplies they suffer accordingly.

While dealing with this point, I must draw particular attention to the question of quality. The Lancashire cotton trade is mainly an export trade, and therefore has to meet the competition of the whole world, and there is probably no industry which has suffered more through hostile tariffs. So far, this competition has been mainly met by producing articles of finer and more superior quality, which were beyond the capabilities of our competitors. The production of such articles required not only greater skill on the part of the operatives, but also longer, finer and better qualities of cotton. India, which produces about 5,000,000 bales, seems to be unable to grow the quality of cotton required. Out of a total consumption of 4,000,000 bales Lancashire only uses about 200,000 bales of Indian cotton, and these solely for the coarsest cloths. Owing to the attacks of the boll-weevil the States are also unable to produce sufficient quantities of long-stapled cotton. The only other country which can produce the quality required is Egypt, but the total annual production of this country is less than a million bales, and unfortunately the cultivable land is limited in quantity and no large increase in production can be expected in the future. The problem, therefore, was not only how to establish and develop new cotton-fields, but also to discover countries where cotton of good and suitable quality could be grown.

Preliminary Inquiries.

With the characteristic thoroughness of Lancashire, the Oldham Chamber of Commerce promptly followed up Mr. Crapper's speech by appointing a committee to inquire into the whole question. A considerable amount of correspondence took place with the Colonial Office, governors, and other colonial officials, with the object of ascertaining what were the possibilities of establishing new cotton-fields in the British Empire. This report was published in November 1901, and may be summarised in one sentence. In the opinion of the committee: "Suitable cotton for the Lancashire trade could be grown in various parts of the British Empire."

The Formation of the Association.

The report was circulated amongst the other Chambers of Commerce, and a copy was sent to the Manchester Chamber, of which I was then a Director. It struck me that there might be great possibilities in West Africa in which I was particularly interested. I got into communication with the late Sir Alfred Jones and also with Mr. J. E. Newton, the President of the Oldham Chamber of Commerce. It is always difficult to get a large number of commercial men together during the daytime, so I invited Sir Alfred Jones and some of the principal West African merchants to dinner on May 7th, 1902, to meet Mr. Newton and other representatives of the manufacturing trade. At that dinner the British Cotton-Growing Association was born.

A general meeting of various associations and representative men was held in Manchester on June 12th 1902, when the Association was formally inaugurated with a guarantee fund of £50,000. Sir Alfred Jones was the first President of the Association, and I should like to take this opportunity of again expressing the immense debt of gratitude owed to his memory by all who are interested in the welfare of the British Empire. It is largely due to his untiring enthusiasm and energy and also to his splendid generosity that the Association has attained its present position. After his death the Earl of Derby very kindly consented to accept the position of President, and I have no hesitation in saying that it would be impossible to find anyone more capable of acting as President of the Association, or who would have devoted more of his valuable time to the work.

The Committee at once set to work, and several cotton experts were immediately sent out to inquire and report with a view to undertaking more active operations. It was soon found that the work the Association had undertaken was very much larger than was originally contemplated, and the Committee began to realise that for a number of years a vast amount of

pioneering work would have to be carried out, and that as this work could not be remunerative at first it would be difficult, if not impossible, to get ordinary capitalists to interest themselves. Consequently, the Association were compelled to commence direct operations, and in November, 1903, the guarantee fund was raised to £100,000.

In January, 1904, owing to another shortage in the supply of American cotton, the situation in Lancashire became so much more serious that it was decided to reconstitute the Association on a more permanent basis and to apply to his Majesty, the late King Edward, for a Royal charter. On August 27th the charter was finally sealed, and shortly afterwards the Association was reconstituted on its present basis with a capital of £500,000, of which £480,000 has been actually subscribed.

I think it is very much to the credit of Lancashire that this large sum of money should be raised solely for the purpose of extending the growth of cotton throughout the British Empire, and without any hope of payment of dividends for many years to come. It is also much to their credit that so many members of the Council have given up valuable time for the good of the cause. It is always much easier for a business man to give money than time, especially so when the time is given without any monetary reward. The strength of the Association is, however, mainly due to its representative character. Its members consist of spinners and manufacturers, merchants and shippers, bankers, insurance companies, shipowners and representatives of all the various industries connected with the cotton trade. What is perhaps more important is the fact that in this great movement capital and labour are co-operating together, and some of the most valuable members we have on the Council are the representatives of the labour associations, while a large amount of our capital has been provided by labour. The late Mr. Joseph Chamberlain urged that England should be taught "to think Imperially." I think we can fairly claim to have even done better than this, and that we are "acting Imperially," for we have started a movement which will have the most beneficial effect on the Empire, and which will, if successful, bring prosperity not only to Lancashire but also to all parts of the British Empire where cotton can be grown. In the words of Mr. Winston Churchill, "cotton is the thread which unites the interests of the industrial democracy with the development of our great possessions across the seas."

Government Assistance.

In view of the representative nature of the Association and of the Imperial objects of their work, the Council had every confidence in appealing to the Government for assistance, and it is a pleasure to be able to state that, no matter which party was in power, the Government have responded both willingly and generously to our representations. It would be invidious to mention individuals, and, indeed, it would take too much time to record the names of all who have helped us in our great work. Prime Ministers, Cabinet Ministers, members of Parliament, colonial governors, colonial officials, and last, but by no means least, colonial directors of agriculture, have all willingly given us valuable help and sympathy. In addition, we have received a considerable amount of financial assistance from the West African colonies, and since 1908 we have received a grant of £10,000 per annum from Imperial Funds. I should, however, point out that this grant is given for specific services, and the amount spent by the Association on these services has always been considerably in excess of the sum received from the Government.

In addition to direct assistance, very great help has been given by the Government in the construction of railways, roads, and harbour works, but naturally all trades benefit by any improvement of transport facilities. As I have often said, there is no better investment of Government money than the construction of railroads in Africa, for it is almost impossible to make a railway in Africa which will not pay. Even that once much-maligned Uganda railway is to-day a financial success, though this is almost entirely due to the development of cotton-growing. Apart altogether from the benefit to cotton-growing and to other trades, all these railways result in large economies in the cost of administration, and every colonial government must benefit from the greatly-increased revenue which naturally follows the increase in trade. The Association, therefore, in urging the Government to construct railways were at the same time giving them sound business advice. The Association are, however, more than grateful for the assistance they have received, and the Council confidently expect that this assistance and co-operation will be continued in the future.

The Work of the Association.

In dealing with the work of the Association, it would take too long to do more than mention the experiments and inquiries which were spread over many parts of the world. They extended

over a large area—India, East, West, and South Africa, the West Indies, Australasia, and elsewhere—in fact, there was hardly a part of the British Empire, where the conditions offered any prospect of success, with which we were not in communication at one time or another during the first five years of our work. As an illustration, I may mention that Malta, Cyprus, Mauritius, and the Fiji Islands were included in our investigations.

When practical work was commenced, we had no technical knowledge of the question, and what added to our difficulties was the fact that there was no one in this country who could give us any definite information or advice, and we had to discover everything for ourselves, with the consequence that some mistakes were made. In the colonies the departments of agriculture were either non-existent or had very little practical knowledge of cotton-growing. The one brilliant exception was the Imperial Department of Agriculture in the West Indies, which was, I believe, formed by the late Mr. Joseph Chamberlain. It is an astounding fact that, although our tropical and sub-tropical possessions are almost entirely dependent on agriculture for their prosperity, the Government had prior to 1900 absolutely neglected the scientific development of agriculture, and such departments as did exist were understaffed and underpaid. Since then, and largely in consequence of frequent representations from the Association, something has been done to put matters right; but I am sorry to say that in most of our colonies the Department of Agriculture is still the "Cinderella" of the establishment.

Amongst other suggestions we strongly urged the formation of a central bureau in London, if it was only for the collection and collation of information, so that one colony could profit by the experience gained elsewhere. The authorities yielded so far to the repeated representations of the Association as to appoint a small scientific committee, but so far I have never heard of its even being called together.

There is one point I must mention in connection with those of our experiments which have been unsuccessful. We have never been afraid of owning up to any mistake we have made. If we found in any particular venture that the results were not likely to justify the expenditure of time and money, as sensible business men we have closed down our work without hesitation and have cut our losses. On the other hand, even when an experiment was not giving immediate satisfactory results, if we thought there were future prospects of success we have continued our work in spite of current losses.

As the work developed, we soon found that it was essential that we should concentrate our efforts on those districts which offered the best prospects of success in the immediate future. We therefore decided to close down our work in those districts where large developments could scarcely ever be expected even under most favourable circumstances, or where, owing to lack of transport, economic progress was for the present out of the question. The main districts where we decided to push on the work were as follows: India, the West Indies, West Africa, Uganda and East Africa, Nyasaland, and the Anglo-Egyptian Sudan. I now propose to deal as briefly as possible with our work in each of these centres.

India.

There are enormous possibilities in India, and the present production is already very large, ranging from 4 to 6 million bales per annum. Unfortunately, as I mentioned before, the quality is unsuitable for anything but the coarsest yarns, and not one Lancashire spinner in a hundred could make any use of Indian cotton. In illustration of this point I should mention that during the great cotton famine it was no uncommon thing for meetings to be held to pray for supplies of cotton. At a meeting held in Stockport, it is related that in the middle of the prayers a voice broke in: "Yea, Lord, but please not Surats." As regards India, therefore, the main efforts of the Association were devoted to the question of improvement of quality; and in 1904 very urgent representations were made to the Secretary of State and to the Viceroy, for it was felt that the Government of India were the only body who could do any good. The main point on which the Association insisted was that, if India could produce a superior type of cotton, the grower would be able to command a wider market and a higher price for his produce. In addition, it was strongly urged that the Department of Agriculture should be strengthened by the appointment of experts who had a scientific knowledge of agriculture, and who were acquainted with the best modern methods pursued in the United States and Egypt.

The Association did not confine itself to representations and advice, but spent over £3,000 in endeavouring to establish perennial, or tree-cotton. I regret to say this experiment was unsuccessful. In 1905 the Council voted a

further sum of £10,000 to be spent by the Government of India in experimental work. Of this amount the sum of £2,000 was actually spent, but afterwards, in view of the heavy demands on the Association in other colonies, the Government agreed that the Association should be relieved of further liability in the matter. Later on the Association made another practical attempt to encourage the growth of superior cotton by offering to establish buying stations and ginning and baling factories, and to supply the best qualities of seed, and to pay the natives the highest possible price for their cotton. The Council, however, stipulated that the Government should take half the risk, and share either the profit or the loss, as the case might be. In consequence of representations from Bombay spinners and manufacturers, which, I have heard it suggested, were perhaps not altogether disinterested, the Indian Government were unable to accept the Association's offer, which would certainly have ensured a better selection of seed and that the native farmer was properly rewarded for his labour. Later on the Government entered into arrangements with the International Federation of Cotton Spinners to carry out some experiments on similar lines. Owing to the war the concession granted had to be cancelled, and the Government then invited the Association to take up the work. Unfortunately the Association were no longer in a position to provide the necessary capital, owing to increasing demands in other fields, and they were reluctantly compelled to refuse this offer.

Although the Association are no longer carrying on any direct operations in India, they are rendering very valuable assistance to the Government by reporting on samples of new types of cotton. Owing to their close connection with the Lancashire trade, both with spinners and brokers, they are in a particularly favourable position to judge as to the suitability for the market of any new type of cotton. When all is said and done, the buyer has the last word in the matter, and if the farmer is to obtain a good price for his cotton it is essential that he should grow the quality which the spinner requires. It is also of immense advantage to the Government to have at their disposal expert assistance and advice, which is at the same time absolutely disinterested.

West Indies.

In some ways our task in the West Indies was easier than elsewhere, for we had the invaluable assistance of expert agriculturists who had been scientifically trained. I refer, of course, to the very able Director and staff at the Imperial Department of Agriculture, who have done such splendid work for the West Indian Islands. It would be a good thing for the colonies, and, indeed, for the whole Empire, if such an organisation existed in every one of our tropical possessions. As might be expected, with this expert assistance our efforts in the West Indies have been eminently successful, and these islands are now producing a sufficient quantity of Sea Island cotton to meet the present demand.

The Association have made several money grants to the West Indies for the payment of experts, the erection of ginning machinery, and providing improved seed. What, however, has probably been of even more assistance, was arranging for members of the Association to visit the islands, when they were able to get into close touch with the planters and to impress on them the necessity of producing the quality of cotton required by the spinner. No less than three separate visits have been paid to the West Indies, and it is largely due to this that these islands are now producing the finest Sea Island cotton grown in the world.

The principal assistance now rendered by the Association is in financing and marketing the crop, and I am glad to say that very little money has been lost in this direction. Undoubtedly one of the principal reasons for the success of the British trader is our national honesty, and we have not had a single instance of our confidence having been taken advantage of in the West Indies.

An immense amount of time and trouble is devoted to the sale of the cotton so as to ensure that the grower will receive the highest possible price. Sea Island cotton is not everybody's cotton, and it is by no means an easy matter to place it to the best advantage. The Association, however, recognise that they are in the position of trustees, and that it is their duty to do their best for any cotton confided to their care—though in any case it would be to their interest to obtain for the planter the highest possible price, for this is naturally the best method of encouraging the planter to continue and extend the industry.

I am glad to say that the planters fully recognise the advantages offered them, and the bulk of the crop is consigned to us for sale.

West Africa.

Notwithstanding the great amount of time and money devoted to West Africa, the results have not been so successful as could be wished. There is an immense area of land available and a large population, but there are many competing products, and it is only reasonable that the native should devote his principal energies to the crop which pays him best, or which he thinks will pay him best. The Council very soon discovered that in West Africa, and one might say in almost all tropical countries, cotton is essentially a black man's crop. Plantations managed by Europeans on which the natives work as hirelings have been a conspicuous failure in West Africa, and there seems to be little doubt that the native will do better when working on his own account than when working for wages. For this reason the main efforts of the Association had to be devoted to encouraging and helping the native to grow cotton. This would, under any circumstances, mean slow progress, and the progress has been slower than was hoped for, owing to the difficulty of establishing a variety of cotton which would give the native a better return for his labour. The general quality of West African cotton is not high, and therefore cannot command a big price.

Owing to the absence of any properly-equipped agricultural departments, the Association undertook the expensive experimental work of seed farms, but in 1910 this branch was transferred to the governments, and everything had to be commenced *de novo*. It takes fully five years to establish any new variety of cotton sufficiently to justify one in distributing the seed to the natives. The consequence is that the prospects of producing cotton of superior quality are now infinitely brighter. This loss of time is to be regretted, but it is solely due to the fact that when the Association commenced their work there were no properly-equipped departments of agriculture in West Africa.

Ultimately the work must be placed upon a purely commercial basis, and therefore during recent years the Association have given particular attention to what I may term the commercial side of the question. Ginning and baling factories have been erected and buying centres established, and the necessary funds provided for financing and handling the crop. The Association have, I am glad to say, received invaluable assistance from the merchants established in West Africa. The buying price is fixed by the Association, and the merchants receive a fair commission for their services. In fixing the buying price the Association have adopted the policy of paying the highest possible price which the conditions of the market would allow, for they fully recognise that if the industry is to make any progress it must be remunerative to the native. This has been the policy of the Association, not only in West Africa, but also in all other colonies where they are established. In proof of this I should mention that, as a rule, the Association's cotton-buying account shows that we just about cover expenses.

The work in Gambia was a failure, as the natives preferred their old industry of growing ground-nuts. In Sierra Leone the rainfall was too heavy for cotton to be a success. In both these colonies the work was closed down some years ago. The Association is now giving up its work in the Gold Coast, because in those districts where there are good transport facilities cocoa is more profitable than cotton, and in the interior the results have not been sufficiently satisfactory to justify the expenditure of more time and trouble. This also applies to the Eastern Province of Southern Nigeria. The best results, so far, have been obtained in Lagos, and in 1913 and 1914 the crops amounted to 14,000 and 13,600 bales respectively. Unfortunately in 1915 the climatic conditions were unfavourable, and it is not expected that the crop will exceed 7,000 bales. In Nigeria, where the conditions are most favourable, very large quantities of cotton are produced every year, but owing to the demand for local consumption the ruling price is generally above the basis of the Liverpool market. The maximum quantity purchased in any one year by the Association was 2,600 bales in 1912. I should mention that the Association provide the Agricultural Departments with the seed required each year for sowing free of charge.

Nyasaland.

In Nyasaland the industry was originally commenced by white planters, and the Association did all that was possible to encourage the growth of cotton by making advances against growing crops. Notwithstanding all possible care, a considerable sum was lost in this manner, and as some of the planters commenced growing tobacco instead of cotton, it was decided to direct more attention to the possibilities of establishing cotton-growing as a native industry. The results have been in every way satisfactory, and in spite of serious transport difficulties and occasional unfavourable climatic conditions, cotton-growing is now

firmly established in Nyasaland as a native industry. The Council are convinced that, although it means slower progress at first, in the long run the largest results will be obtained when the industry depends principally on native farmers working on their own account.

The Association have erected four ginning factories in Nyasaland, they have opened up a number of buying centres, and are acting in the closest co-operation with the Government and the Agricultural Department. The Association also provide, free of charge, all the seed that is required for distribution amongst the natives.

The one great disadvantage in Nyasaland is the great difficulty of transport, and when it was decided to extend the Shire Highlands railway from Port Herald to Chindio, so as to bring the colony into economic touch with the Zambesi River, the Association and their friends raised £36,200 of the required capital.

Uganda.

In Uganda the work of the Association was not carried on directly, but through the medium of the British East Africa Corporation. This arrangement has been terminated recently, and the Association is now conducting direct operations. Although the Association did not at first undertake any direct work, except through the Corporation, they were in constant communication with the Colonial Office and with the local authorities on the various problems which were continually arising in connection with the industry.

In Uganda cotton-growing is purely a native industry, and thanks to a fertile soil, favourable climatic conditions, a large and intelligent population, coupled with an excellent form of native government and good transport facilities, the industry has progressed most rapidly. In the early days there was no efficient Department of Agriculture, and large quantities of seed of various varieties were distributed indiscriminately, and in any one shipment from Uganda one could find cotton of every variety and nature mixed together. Mainly in consequence of the efforts of the Association, this has now been put right, and under the able administration of the Department of Agriculture, Uganda cotton is improving in quality, and is acquiring a well-deserved reputation in the Liverpool market.

This is a very good example, where the industry depends solely on the natives, of the necessity of the distribution of seed being placed under strict Government control, or in the hands of an impartial body like the Association. If the supply of seed depends on irresponsible individuals, mixture and deterioration are bound to occur. This is the most vital question in connection with cotton-growing, for unless the seed issued to the natives is sound in quality and pure in strain everything else is thrown away. One may have the most perfect climate and the most excellent soil in the world, and the best methods of cultivation; but unless the seed sown is of good quality all these advantages are utterly wasted.

In addition to representations to the Government in connection with the quality of seed, transport difficulties and other various problems, the Association rendered most valuable assistance in the form of very large loans to the British East Africa Corporation. The money lent was utilised for the erection of ginning and baling factories, and for the purchase of cotton. It is perhaps not generally realised how large an amount of actual cash is required for moving a cotton crop. Even under favourable conditions some considerable time must elapse between the date when the cotton is bought and when actual shipment takes place. Afterwards, when bills of lading and documents are available, finance is easier to arrange, though, owing to the delays in selling any cotton which has not acquired a recognised status on the market, bankers are not always so ready to provide the necessary finance, except with ample margin or on onerous terms.

The Association have rendered invaluable assistance in this direction, for owing to their position they are able to obtain exceptional facilities from bankers, and the Council have always made a point of giving their customers the benefit of the favourable terms which are granted to the Association. It is no infrequent occurrence for the Association to have out on loan against cotton and machinery well over £500,000.

The first record of exports of cotton from Uganda was in 1904, when fifty-four bales were shipped. In 1908 the shipments amounted to 4,000 bales, and in 1911 there was a further increase to 20,000 bales. In 1914 it was estimated that the crop was over 40,000 bales, which, together with the seed, would represent a money value of close on £500,000. When one considers that twelve years ago cotton-growing was non-existent in Uganda, it will be generally admitted that this is a wonderful result to have achieved in so short a time.

ANGLO-EGYPTIAN SUDAN.

It is only in recent years that cotton-growing on a large scale has been possible in the Anglo-Egyptian Sudan. Prior to the completion of the Suakin-Berber Railway in 1906 the only district where cotton was grown for export was at Tokar on the Red Sea. Thanks to careful management on the part of the Government, Tokar is now annually producing about 8,000 bales of cotton of very fair quality, but as the crop depends on a rather uncertain supply of irrigation water, coupled with very irregular rains, there is considerable variation both in the quantity and quality of the cotton.

When the railway was completed the Association offered their services, but were informed that their help was not required, and no further steps were taken in the matter.

In 1910 the Council were approached by the Sudan Plantations Syndicate, who invited their co-operation in pushing on the cultivation of cotton, with the result that the Council took a large financial interest in this company, and I was appointed to the board to represent the Association's interests. The Council were so impressed with the possibilities of the country that they arranged for a special deputation to visit the Sudan in 1912, and since then we have done all in our power to assist in the development of the industry.

It would take too long to describe in detail the possibilities of this wonderful country, but I should mention that there are five distinct and separate propositions as follows :—

(1) *Tokar.*—Good possibilities of producing 10,000 to 20,000 bales in the immediate future.

(2) *Khartoum and North.*—Fair prospects for 5,000 bales or more of good quality of Egyptian cotton with further possibilities in the future.

(3) *Gezira.*—One of the finest cotton propositions in the world. There are possibilities of raising 50,000 bales of high-class Egyptian cotton in the immediate future, and there is no reason why the production should not be increased to 250,000 bales or more within the next ten to fifteen years, with ultimate possibilities of an annual production of more than 1,000,000 bales. As I stated before, the Egyptian crop is less than a million bales.

(4) *Rain-grown Cotton.*—This is a proposition for the future, but there is land enough to grow millions of bales.

(5) *Gedaref and Kassala.*—Here there are also fair possibilities of producing considerable quantities of both rain-grown and irrigated cotton.

The Association have rendered most valuable assistance in financing and marketing the cotton, and so ensuring that the native should receive the best possible price for his crop. Their main efforts have, however, been devoted to educating both the country and the Government as to the great possibilities of the Sudan, and they insisted on the fact that it was the duty of this country to provide financial help to the Sudan Government. These efforts culminated in a deputation to Mr. Asquith on January 23rd, 1913, when they received a promise that the Government would guarantee the interest on a loan of £3,000,000 to be raised by the Sudan Government for the construction of irrigation and other works in the Sudan. Unfortunately, before matters were sufficiently advanced to justify the issue of the loan, war broke out and everything had to be postponed. In the meantime two experimental pumping stations have been established and are in full working order. The results obtained have been most satisfactory and are most promising for the future.

I should mention that a most interesting Socialistic experiment has been inaugurated at these two stations. Lord Kitchener was, I understand, much disturbed by the fact that in Egypt the cultivator on whom the brunt of the work falls only receives a very small proportion of the proceeds of his crop as a reward for his arduous labours. He was determined that in the Sudan the farmers should not be left at the mercy of capitalists, and I understand that he himself drew up the proposals which have since been adopted. The scheme is shortly as follows : The total proceeds of the crop are pooled together and divided into shares. The Government provide the land and the water and receive 35 per cent. of the total. The syndicate who look after the financing, direction and management receive 25 per cent., leaving 40 per cent. for the farmer as the reward for his time and labour.

Lord Kitchener is much to be congratulated on the boldness and simplicity of this scheme, which will, at any rate, ensure that the man who actually grows the crop will be able to obtain a fair reward for his labours, which is, unfortunately, not always the case in many parts of the world.

Before leaving this point I should like again to draw attention to the fact which I previously mentioned, that Lancashire urgently requires increased supplies of cotton of superior quality. It is becoming more and more difficult to obtain cotton of suitable quality for fine yarns, and this is clearly shown in the price of Egyptian cotton.

In the five years ending in 1915 the American crop averaged 14,400,000 bales, as compared with 8,300,000 bales in the five years ending in 1895, an increase of 6,100,000 bales, but the average price has increased from 4¼*d.* to over 6½*d.* If we eliminate 1915, when the price was unduly depressed owing to the war, the average would be over 7*d.* per lb., giving an increase in twenty years of 1¾*d.* per lb. During the same period the Egyptian crop has increased from an average of about 900,000 to 1,500,000 bales of 500 lb., an increase of only 600,000 bales in twenty years, but the average price has increased from 5¾*d.* to 10½*d.*, a difference of no less than 4¾*d.* per lb. This means that whereas twenty years ago Egyptian cotton commanded a premium of only 1*d.* per lb. over American, the average premium to-day is over 3*d.* per lb. This increase in premium is almost entirely due to the growing demand for, and the consequent scarcity of, long-staple cotton. One therefore cannot resist the conclusion that it is the duty of the Government, and, of course, of the Association, to do all that is possible to develop every district capable of growing high-class cotton, for it is no exaggeration to state that on the success of these efforts depends the whole future—indeed, the very existence—of the Lancashire cotton industry.

Commercial and Other Work.

Before I conclude this summary of the work of the Association I must draw attention to what I may term the commercial side of our work. We do all we can to help planters and others by making advances against crops and by financing the cotton after it is gathered, and our charges are made as light as possible. Further, we accept risks which would not be undertaken by ordinary commercial firms. We look after shipment, pay the freight, see that the cotton is properly insured, and afterwards superintend the sale of the cotton and seed, and naturally make a point of obtaining the best possible price. For these services we charge a small commission, which provides a substantial sum towards the payment of our standing expenses. We also supply machinery, plant, baling material, seed, etc., on easy terms of repayment. The value of these services can hardly be over-estimated. One great difficulty which every tropical planter has to face is how to obtain a fair price for his produce, but everyone who grows cotton in co-operation with the Association has at least the satisfaction of knowing that there is an "honest broker" at home who will look after his interests like a brother.

In addition to this "commercial" work the Association is also in constant communication with the agricultural departments and other officials in the colonies, and a large amount of time and correspondence is devoted to discussing the many problems which are connected with the development of cotton-growing throughout the Empire. I should like to take this opportunity of expressing our thanks to the numerous officials who have so often given up some of their well-earned leave to come to Manchester to discuss these problems with us. There is no doubt that even half an hour's conversation is worth yards of letter-writing.

The Association owe an immense debt of gratitude to the Duke of Marlborough for inaugurating the conferences at the Colonial Office. At these meetings representatives of the Association hold friendly discussions with the officials, and so easily and expeditiously dispose of problems which might otherwise be insoluble. Notwithstanding these meetings, we have to carry on a voluminous correspondence with the Colonial Office, and the letters which have passed between us during the last nine years fill sixteen good-sized books.

My object in giving this somewhat lengthy description of the work of the Association is to enable you to understand the enormous task we have undertaken, and the almost overwhelming nature of our work, and so to appreciate the additional difficulties we have had to face in consequence of this terrible war.

Fall in Price of Cotton.

The most serious problem which the Council had to consider when war was declared was the big fall in the value of cotton. All systems of credit and of international exchanges, which had taken almost centuries to build up, practically disappeared in one day, and no one could say what would be the effect on the price, not only of cotton, but also of every article of produce and of every security, whether it were land or buildings, or stocks or shares.

During the first half of 1914 the price of American cotton had averaged about 7*d.* per lb. Notwithstanding the fact that the Liverpool and New York markets were closed, by the end of October the price had fallen to 5*d.* per lb., and in the middle of December Middling American was almost unsaleable at 4¼*d.* per lb.

This meant a big reduction in the buying price to the planter, and serious as the effect might be

in countries like the United States, India and Egypt, where cotton-growing had been established for half a century or more, much more anxiety was felt as to the results it might have in those countries where cotton-growing was of recent introduction. In cases where the industry depended on European planters the situation was not quite so serious, for they would, at any rate, appreciate the difficulties of the market. Where, however, as was the case generally, cotton-growing depended solely on the natives, the fear was that if the buying prices were very much reduced they might be seriously discouraged, and that they would reduce their planting of cotton, and might even abandon the industry altogether. As can be imagined, the Council passed through a most harassing and anxious time. However much they might desire to save this industry, which had taken so much trouble and expense to build up, the capital at their disposal was only limited. They, however, decided that this was a time for bold and generous action, and even if the Association were to suffer serious losses in maintaining the industry the money would be well spent from an Imperial point of view.

Policy of the Association.

The policy the Council laid down was that this was not a time to be thinking of making money, and therefore that it was essential that the native producer should receive a generous price for his cotton. It was also the paramount duty of the Association to ensure, as far as possible, that every single native farmer should be able to dispose of his cotton even if it were at a low price. In those districts where the Association had the buying in their own hands they must pay the highest possible price the market would allow. In other colonies, where the buying was done through other channels, if the buyers were not prepared to help by working for a time with a small margin of profit, or if they were inclined to leave cotton-buying alone as not sufficiently profitable, it might be necessary for the Association to step in and take their place.

It will be agreed that the Association adopted a bold and statesmanlike policy, and that the Council deserve the highest commendation for risking, as they did, the whole of the liquid capital of the Association. It remains to be seen what the financial result will be, but if it means that half the capital of the Association has been lost, it will have been in a good cause.

The adoption of a policy, however good it might be, was not sufficient in dealing with difficulties of this sort, and the Council immediately set to work to devise practical measures to meet the circumstances of each particular case. I propose to give you, as shortly as possible, an account of the actual measures taken by the Association to try to save the industry, but I should mention that we have received no financial help whatever from the Government, although we were voluntarily taking on our shoulders a task which should more properly have been performed by the Government. What, however, did more than anything else to save the situation was the fact that, after touching a minimum price of $4\frac{1}{4}d.$ in December, 1914, the price of cotton began to rise as soon as the Liverpool market was reopened. In January, 1915, the price again reached $5d.$, and afterwards remained slightly above this level, with fluctuations between $5d.$ and $5\frac{1}{2}d.$, until the end of August. Afterwards there have been very big fluctuations in the price, which is to-day about $8d.$ per lb., but this last rise came too late to help us in our work.

Finance.

One of the most serious difficulties the Council had to face was that of finance. Cotton is essentially a cash crop, and this involves the provision of a large amount of silver coin for purchasing the cotton, which again means the arrangement of the necessary bank credits. No one could foretell how the banks were going to be affected by the war, and I think it is very much to the credit of our banking friends that they boldly faced the situation and provided us with credits amounting to over £500,000 to enable us to finance the various crops. This also reflects the greatest credit on the reputation of the Association. Had it not been for the high character we have acquired for careful and honest business methods I do not suppose we could have obtained these credits. What helped us most was the recognition by the banks of the fact that we were working for no selfish motives, but for the good of the Empire, and consequently we were able to obtain financial assistance which would not have been granted to ordinary commercial firms. Perhaps some day the Association may be compelled to work on strict business lines, but I am convinced that in the interests of the Empire it is essential that the philanthropic character of the Association should be maintained for many years to come. Perhaps the best solution of the difficulty would be the establishment of the Association as a permanent "Trust."

Nigeria.

In Nigeria, although cotton was bought mainly by the merchants, as our agents, the price was fixed by the Association. Prior to the war the buying price was $1\frac{1}{8}d.$ per lb. of seed-cotton. As it takes about $3\frac{3}{4}$ lb. of seed-cotton to give 1 lb. of lint, this means a first cost of about $4\frac{1}{4}d.$ per lb., which, after allowing for cost of ginning and baling, freight, and other expenses, was equal to about $6\frac{5}{8}d.$ per lb. in Liverpool.

As I mentioned before, the Liverpool price had dropped to $4\frac{1}{4}d.$ per lb., and even if we reduced the buying price by 50 per cent., or to $\frac{9}{16}d.$ a lb., we should have no margin left to cover working expenses. The merchants most generously agreed to sacrifice $\frac{1}{16}d.$ per lb., or half their commission; Messrs Elder, Dempster & Co. arranged to allow a rebate of 25 per cent. off the ocean freight; and the Nigerian Government also agreed to a rebate of 25 per cent. on the railway freight. These concessions together amounted to slightly over $\frac{1}{8}d.$ per lb., and the Council decided to fix the buying price at $\frac{3}{4}d.$ per lb., which would involve a loss of $\frac{1}{16}d.$ per lb. in addition to the working expenses. The buying price was subsequently increased to $\frac{7}{8}d.$ per lb., when the Liverpool price rose to $5d.$, and it was afterwards raised to $1d.$, or only $\frac{1}{8}d.$ below the original price. I think it will be conceded that the Council undertook more than could have been reasonably asked of them, and especially so as the arrangement will probably result in a loss to the Association of over £10,000.

Nyasaland.

In Nyasaland the buying was partly in the hands of the Association, and was partly carried out by local firms. When the Liverpool price fell the latter withdrew from the market, and the Association were left to bear the burden single-handed. The Council boldly faced the situation, arranged the necessary finances, and purchased practically the whole of the native-grown crop at prices which were considerably above the market value. This must involve some loss, especially as they have had to pay, not only here, but from other parts of the Empire, enormously increased rates for freight and insurance. Let us hope that the Government will tax heavily all those who have utilised the opportunity afforded to them by the war to make extra profits out of the misfortunes of their fellow-countrymen. In any case it is no benefit to the industry to have to pay increased rates, even if the Government were to take the whole of such extra profits.

Uganda.

The situation in Uganda was the most difficult of all. Cotton was the main export industry of the country, and unless means could be provided for marketing the crop it would be a most serious disaster for the colony. The natives would suffer most severely, and the Government would have to face a serious financial deficit. There was also grave danger that the natives might be so discouraged that they would abandon the industry altogether, and if this were to happen it might be impossible to revive it. This would have been a serious disaster for the colony, and the Government revenue would have fallen off so seriously that a grant-in-aid from the Home Government would be required to meet the deficiency. In consultation with the Colonial Office and two of the principal buying companies the Association drew up a very comprehensive scheme, involving a credit of £600,000, which would provide all the buying and ginning firms with funds to deal with the whole of the native-grown crop. The Treasury also agreed to help in case of need. The Association were also prepared to consider any modification of the scheme which would enable the buyers to pay a fair price to the natives, and which would at the same time give the former a fair margin towards working expenses.

I regret to say that the principal local buying and ginning companies took a very narrow-minded view of the situation, and were not prepared to accept the policy put forward by the Association, that this was not the time to be thinking of making money, and that every effort should be made to encourage the natives to continue the industry by paying them the highest possible price for their cotton. They strongly opposed the scheme, which had therefore to be abandoned and other steps devised to meet the difficulties of the situation.

Unfortunately during these negotiations valuable time had been lost and the crop was beginning to come forward. The following quotations from the annual report of the Director of Agriculture will, perhaps, best illustrate the difficulties of the situation:—

"For over six months of the year cotton was practically unsaleable, and the growers were left for months with the crop on their hands and wholly unable to provide adequate storage accommodation. Large areas were neglected and uprooted, and in some cases the cotton was burnt and otherwise destroyed, as the producers gave up all hope of being able to sell their crop."

"The position was aggravated owing to the fact that some firms, usually large buyers of

cotton, were out of the market. Even under ordinary circumstances it is with the greatest difficulty that the crop is moved."

The Council therefore had to make hurried arrangements for direct operations. Luckily one of their West African managers, Mr. Worsley, was already on his way to Uganda, where he had been sent to inquire and report on the industry generally. A credit of £150,000 was arranged, and two of the smaller companies voluntarily placed their staff and their ginning factories at our disposal, and the Government arranged to lease to the Association a third factory belonging to a German firm which had been closed down owing to the war. The buying price was first fixed at 5 cents of a rupee, and was subsequently raised to 5½ cents, which is equal to about 5½*d.* per lb. of Middling American in Liverpool. I am glad to say that, notwithstanding the hurried and rather inadequate arrangements, the Association were able to deal with no less than 9,000 bales, or fully one-third of the whole crop. Prior to the intervention of the Association the other firms were paying very low prices for the cotton, but afterwards they had to raise their prices or stop buying. It was a misfortune that the Association were limited in the quantity they could buy owing to the small capacity of the ginning factories at their disposal, otherwise they might have bought a very much larger proportion of the crop. It is no exaggeration to say that the bold and prompt action taken by the Council has saved Uganda from a certain disaster, and even if it does, as is probable, involve the Association in considerable losses, the Council will consider the money well spent.

One could not have a better example of the immense value to the Government of a philanthropic body like the Association, and of the danger of leaving the natives at the mercy of ordinary commercial firms. The Council have since been informed that some of the other firms consider it most unfair that the Association should have intervened as they did. These gentlemen have, however, no one but themselves to blame, for if they had been willing to help, even in the slightest degree, the Association would never have intervened and would further have given them all possible help.

The Government fully appreciate the action taken by the Association, and in February, 1915, a letter was received from the Colonial Office, stating that :—

"Mr. Harcourt desires to take this opportunity of expressing his warm appreciation of the public spirit which the Association have shown in their desire to take all possible steps to safeguard the industry."

Anglo-Egyptian Sudan.

In the Anglo-Egyptian Sudan the situation was also one of considerable difficulty. The industry is one of the most important in the country, and, owing to the war, all ordinary channels of credit were closed, and the usual buyers were not in a position to operate. Cotton-growing in this country is almost entirely a native industry, and there was a fear lest the natives might not be able to dispose of their crops except at ruinous prices. The Association were approached by the Government through the Sudan Plantations Syndicate, and the council were able to arrange for a credit of over £200,000, and consequently the whole of the Sudan crop was marketed at not unsatisfactory prices.

The following extracts from letters from Sir Reginald Wingate will show that the assistance rendered by the Association has been much appreciated :—

"Khartoum, January 29th, 1915.

"In this country it is not only a question of securing for the cultivators a fair price for their 1915 crop, but of preventing, if possible, their faith in cotton as a source of profit being shaken."

"Khartoum, March 8th, 1915.

"I should like to take the opportunity of saying how much I appreciate your cordial help in a difficult question, which now offers every prospect of a satisfactory solution, and I am grateful for your kind offer of future assistance. It will be a great benefit to the future of cotton-growing at Tokar that, in a year like the present, the cultivator has been provided with an opportunity of selling his cotton on the spot for cash."

West Indies.

In the West Indies, where the bulk of the cotton crop is grown by white planters employing native labour, the outlook was most serious. The crop consists almost entirely of the best quality of Sea Island cotton, which is used for spinning the very finest yarns, the principal demand for which is for lace-making. Owing to the war there was an absolute cessation in the demand for luxuries, and West Indian cotton was utterly unsaleable even at ruinous prices. There was therefore the gravest danger of the planters abandoning the cultivation of cotton, and more especially so as sugar was fetching high prices. The Council approached the Fine Cotton Spinners' and Doublers' Association, who are the largest users of Sea Island cotton, and I am glad to say that

this company took a wise view of the situation and offered to guarantee a minimum price for the 1915 crop, and the price offered was very much above the value then ruling in the market. Since then there has been a considerable rise in the value of Sea Island cotton, and it is therefore to be hoped that the industry will continue as before.

Results Obtained.

The Council are not given to blowing their own trumpet, and therefore I think it is only right that the public should be informed of the action they took to meet a most difficult and serious situation. I think it will be generally admitted that they adopted a broad and statesmanlike view of their duties. I do not pretend that better measures might not have been devised to overcome the many difficulties with which they were faced; but it must not be forgotten that business and finance were in a state of chaos, and that there was little time to be lost, and consequently everything had to be done in a hurry. Nor should it be forgotten that the liquid capital of the Association was little over £100,000, and this would not go very far in financing a crop worth over £1,000,000. I should also mention that although the Treasury had promised to find a considerable sum of money to save the Uganda crop in consequence of the Association's scheme having to be withdrawn, the Government were not asked to find one single penny either in Uganda or elsewhere, and the Association have had to bear the burden alone.

The question naturally arises as to the results of the Association's action and whether the industry will continue to progress in the future as it has done in the past, or whether it has received a set-back from which it will take a long time to recover. It is a little difficult to give a definite opinion on this point at the present moment, but it is of no use pretending that the situation is any better than it really is. The view taken by the Council is that, as far as can be judged at present, the industry has received a set-back, and that it will require careful nursing to set it again on its progressive march. In order to enable you to appreciate the position as it now stands, I propose to give you a short *résumé* of the reports we have received from the various centres in which we have been operating.

Lagos.

In Nigeria we have two main districts, along the Lagos railway between Lagos and Jebba on the River Niger, and in the Northern Provinces along the railway between Jebba and Kano. Our reports from Lagos show that a smaller quantity of seed was distributed in 1915 than in 1914. Luckily the climatic conditions have been favourable, and as it may be possible to raise the buying price to the old standard of $1\frac{1}{8}$*d.* per lb., it is probable that this year we shall see as large an area planted as before. Steps are being taken to introduce an improved variety of cotton, and the Association have guaranteed an extra bonus for all cotton grown from Government seed. If these efforts are successful we may see cotton-growing extend rapidly in this district.

It is rather difficult to know how much cotton has been planted in Northern Nigeria, but I am glad to say that our latest reports state that so far the Association have purchased a much larger quantity of cotton than in 1915. Here also efforts are being made to establish a better quality of cotton.

Although the Association may be compelled, for financial reasons, to close down outlying stations and to restrict their operations to the railway, I think the prospects are distinctly promising, and that the set-back in Nigeria will be only of a temporary nature.

Nyasaland.

There is no doubt that in Nyasaland both the planters and the natives have suffered considerable losses owing to the fall in prices, which have been added to by the largely increased rates of freight demanded by the steamship companies. As I stated previously, the Association did all they could to alleviate these losses by paying the highest possible price for the cotton. The officials also did their best to explain to the natives that the low prices were due solely to the war, and were therefore temporary, and it is satisfactory to know that there is likely to be a considerable increase in the planting of cotton in 1916.

Uganda.

In Uganda I am afraid that we are going to have a serious set-back, and it is impossible to say at present when the industry will recover from it. It may take several years before cotton is planted even as largely as in previous years, and I am afraid one must not look for any large increase in the immediate future. As was stated in the report of the Director of Agriculture, the natives, being unable to find a market for their produce, uprooted the plants and burnt and destroyed

the cotton which had been picked. It is more than a misfortune that the Association were not previously established in this colony, and that they were only able to commence operations when the season was well advanced. Had it not been for their intervention—late as it was—it is more than probable that cotton-growing would have disappeared entirely and finally in many districts in Uganda.

In view of the seriousness of the situation the Council have decided to continue their operations for at least another season, and it is more than probable that the Association will have to go on working in Uganda for several years to come. This, however, must depend on our financial position. Our subscribed capital is about £480,000, of which £178,000 had been spent on experimental work up to December 31st, 1914. This amount will probably be increased to £200,000, when we allow for the losses incurred in 1915 in our efforts to save the industry. It therefore stands to reason that we cannot afford to devote much more money to philanthropic or unremunerative work.

Anglo-Egyptian Sudan.

In the Sudan I think we can look confidently to the prospects for the future. Owing to the help rendered by the Government in co-operation with the Association, the natives received quite a fair price for their cotton. It is, therefore, expected that cotton will be planted as largely as before, and that its cultivation will continue to increase.

There can, however, be no large increase unless the money is found for the construction of the necessary works for the irrigation of the Gezira plain. No doubt after this war is over the financial position will be one of the gravest difficulty; but however much the Government may be compelled to cut down expenditure, I should consider it an economic blunder, and almost a breach of faith, if they were to go back on their promise to guarantee the interest on the loan of £3,000,000 to the Sudan Government. It should not be forgotten that this is not a mere paper scheme. It has already been proved. We have at the present time two large experimental areas in full working order, one of which has been under cultivation for nearly five years. "Experimental" is really the wrong word to use, for these plantations are respectively about 1,500 and 2,500 acres in extent, and are therefore business propositions. I am not at liberty to give you the figures, but I can assure you that these two propositions are successful already, even from a purely commercial point of view. The full scheme, therefore, cannot fail to be a success, and it would be an obviously mistaken policy to delay the issuing of the capital through any mistaken idea of economy, for I am convinced that the British Government will never be asked to find a single penny through failure of the Sudan Government to provide the interest on the loan.

Beneficial Results of Cotton-Growing.

While on this point, I should like to draw your attention to the beneficial results which have accrued to the Empire in consequence of the work of the Association in extending the cultivation of cotton. An estimate was recently submitted to the Government, showing that the Colonial revenues were benefiting to the extent of no less than £130,000 per annum in direct consequence of the cultivation of cotton. This figure could easily have been increased to £150,000 without overstating the case. It was also shown that the revenues of the steamship companies derived from cotton was over £100,000 a year. Insurance companies, bankers and others have also derived large additional revenue in consequence of our work. Nor are the benefits confined to the above-mentioned interests. It must not be forgotten that every pound's-worth of cotton which is produced for export, and which does not replace some other product, means a corresponding importation of manufactured articles or other goods. The cotton and seed produced under our auspices now amount in value to over £1,000,000 per annum, and it is no exaggeration to state that we have increased the demand for British manufactures to the extent of at least £500,000 a year.

This fact is one of profound importance when we come to consider the growing necessity for new markets for our manufactures, a necessity which will probably be much more pressing after the end of the war. It must not be forgotten that, generally speaking, we are creating an absolutely new trade, and enabling the natives to produce an article for export in those districts where an export trade was previously impossible. Cotton is an article of high value, and can therefore stand considerable expense for freight. It would be folly to attempt to grow maize or other products of low value in the heart of Africa, as the cost of freight and charges would be almost as much as the total value of the article. Cotton, however, can be, and is at the present moment being, produced in the centre of Africa on an economic basis.

The Future.

Before I conclude I must say a few words about the future. About the necessity for our work there can be no doubt. In the five years ending in 1895, the United States used 31 per cent. of their crop. In the last five years their requirements have risen to 37 per cent., and in 1915 they used over 6,000,000 bales. The crop now being marketed is probably not more than 11,500,000 bales, and it is expected that this year their consumption will be at least 6,500,000 bales, or over 56 per cent. of the total crop. We must face the fact that, sooner or later, America will need almost the whole of her crop for her own requirements, and therefore, unless new cotton-fields are rapidly developed, most of our cotton-mills will have to stop, and a large proportion of the population will be compelled to emigrate in order to find employment.

Anyone who is interested in the question ought to read a book recently published by Mr. John A. Todd, Professor of Economics at the University College of Nottingham, entitled "The World's Cotton Crops." It is the best, and I might say the only, book giving an account of cotton-growing throughout the whole world. The last chapter deals with the effects of the war, and the concluding passage is well worth quoting:—

> "But one thing is certain: when the war is over we shall require an increased supply, especially of fine cotton, and we must look for it mainly to our own Empire, especially in India and Africa. We shall then want, not merely a British Cotton-Growing Association, with a capital of a paltry half-million, but an organisation of the size of a State Department, with all the Governments of the British Empire behind it, and a capital of about as much as is spent on this war in a day, say, £10,000,000."

Our work so far has been mainly experimental. We have been examining, inquiring, and experimenting in order to ascertain which colonies offered the best prospects of success. What we have to do now is to extend and develop these various ventures on a very much larger basis. So far from having come to an end of our work, we are really only just commencing it. An annual production of 100,000 bales, though worth over £1,000,000, is infinitesimal when one remembers that Lancashire uses over 4,000,000 bales of cotton every year. Further, there are plenty of experiments yet to be carried out, and there are large districts as yet untouched. Our work in Northern Nigeria is only just beginning, and it is more than probable that the new railway from Port Harcourt to the Benue River will open up large cotton areas. There is a large extent of country in Nyasaland and North-Eastern Rhodesia absolutely undeveloped, and we have only just begun to realise the large possibilities in Uganda. In the Sudan, as I mentioned before, there is an immense amount of work to be carried out in the immediate future, and there are large districts in the south with enormous possibilities for later development. No one can say what may be the result of the war and whether additional territories may be added to the British Empire. I may, however, mention that German East Africa is a country where a fair amount of cotton is already grown, and that in Mesopotamia there are possibilities of growing sufficient cotton to keep half the spindles of the world fully employed.

You will, therefore, realise that we have an immense amount of work before us, if we are able to undertake it. There are, however, two essentials—ample means, which we certainly do not possess at present, and unfailing and enthusiastic assistance from the Government. I do not mean financial assistance but hearty co-operation in our work, and such help as can be given by the construction of railways, roads, and other facilities which benefit all trades alike. This assistance we have received in the past, and the Council confidently expect that we shall continue to receive it in the future, for without it it would be useless attempting to continue our work.

It has been suggested that the time has come for the Association to work on purely commercial lines. In the opinion of the Council this is a mistaken idea. There are still many experiments to be carried out and a great deal of pioneering work to be done. As I explained before, this work is unremunerative, and it is not to be expected that ordinary commercial firms would face the losses which are unavoidable. Further, in consequence of the war still greater efforts of a philanthropic nature will be required to maintain the industry even at its former level, and much more will have to be done if any extension is to take place. The Council are convinced that if the Association are compelled to work on purely commercial lines, and if they have to make the extension of cotton-growing subservient to the earning of profits, it will be nothing less than a calamity for the Empire.

Amongst the lessons which I hope this terrible war should teach us, there is one which I trust we shall not fail to learn and to apply in a practical manner—that we should grow, as we

can do, within the British Empire, all the cotton required by our mills, and so make them perfectly independent of all foreign countries. The war has undoubtedly given the cause of cotton-growing a set-back, but I am glad to say that the Council are in no way disheartened or dismayed. If we can obtain the whole-hearted support of the Government we have every intention of continuing to develop to the best of our ability what has been aptly described as "The greatest Imperialistic movement of modern times."

DISCUSSION.

The Chairman (Sir Daniel Morris, K.C.M.G., D.C.L., D.Sc.), in opening the discussion, said the author had given an admirable account of the work of the British Cotton-Growing Association, and he was sure everyone present must be impressed by the magnificent work the Association had been carrying on, for the last twelve or thirteen years, in all parts of the world. He did not think that work was as well known as it ought to be, but people in Lancashire and in the various colonies where cotton was grown all felt the very greatest gratitude to the Association for the way it had helped them through bad times and enabled them to continue their work. As regards the various grades of cotton, the highest class was that known as Sea Island cotton, which was exceedingly strong. It had hitherto been grown in the Southern States of America, especially in South Carolina and the Sea Islands, and was originally obtained from Barbados. When the attempt was first made to introduce cotton-growing into the West Indies, he went to the United States to make inquiries as to the possibility of growing the ordinary American cotton; but there were many difficulties in the way of doing so, one being that the price was too small for the intensive cultivation that was carried on in the West Indies. In the following year he went to the United States again to study the Sea Island cotton, and he finally decided to purchase a large quantity of the seed to take to the West Indies. That seed was distributed to the planters there, and in the first year they planted about 5,000 acres with it. The cotton was shipped to Liverpool and was bought by the fine spinners to make yarn for such articles as lace, chiffon, and other materials of that kind. Brussels lace was also made from Sea Island cotton, which was really the finest in the world. When the industry was first started in the West Indies, people in the Southern States of America felt quite sure they could hold their own, and they were very surprised when, in the first year that cotton was grown in the West Indies, it obtained 2*d.* a lb. more than that which was grown in the Southern States. They were also surprised at the large quantities of cotton that the West Indies produced. He believed the Fine Spinners' Association in Lancashire largely depended upon the supplies from the islands. The very best Sea Island cotton exported from the West Indies had obtained a price of 4*s.* per lb., although that of course was in very small quantities and under exceptional circumstances. That cotton was grown in an island that was visited by a terrible eruption in 1902, and at one time it was thought the island would have to be abandoned altogether as being too dangerous, but that little island was now coming to the front as producing the finest cotton in the world. The cotton could be grown as an intermediate crop with the sugar-cane, so that it did not interfere with the cultivation of sugar. With regard to the work of the agricultural departments, to which the author had referred, the Imperial Department of Agriculture in the West Indies was started by the Home Government as an experiment, on the recommendation of a Royal Commission, to see whether some kind of scientific agriculture could not be established in certain parts of the British colonies. The Department had proved a great success, and at a dinner given at the West Indian Club recently Mr. Asquith said the experiment was one of the most gratifying undertaken by any Government, because the results were so very striking and were brought about in so short a time. Similar agricultural departments had now been established in practically all parts of the tropics—in India, Ceylon, the Malay States, Mauritius, the Gold Coast, Sierra Leone, Upper and Lower Nigeria, and Fiji. Of the men that were trained in the Department of Agriculture in the West Indies, one was at the present time Director of Agriculture in Mauritius, another held the same post in the Malay States, and a third in Fiji. He thought the author was rather too pessimistic about the present position of scientific agriculture in the tropics. In the last few years there had been a considerable improvement in that direction, and planters in the tropics were now convinced that science could help them a great deal. As a proof of the value of science in assisting the practical planter, he might mention that there was a certain disease prevalent at one time amongst sugar-canes, caused by the sugar-cane moth, which resulted in a loss of several thousand pounds a year. A young man from Cambridge, who had never seen a sugar-cane before in his life, was sent out as Official Entomologist to the Department, to trace out the life history of the moth and see whether the disease could not be stamped out. The planters did not believe he could do it, but in twelve months he was successful, and that helped to convince them of the benefits of science as applied to agriculture. That confidence was now extending to different parts of the Empire, and he did not think the British Cotton-Growing Association would have the same difficulties to contend with in the future as they had had in the past.

Mr. Theodore Walker asked what country was the natural habitat of cotton, and also wished

to know whether the cotton plant was an annual or a perennial. He noticed that the author did not refer to the carriage of cotton, which was a very important matter. In the West Indies it was quite a simple business to export cotton, as the islands were small, and therefore no part of them was very far from the coast; but in Uganda, for instance, it was a very different matter, as it had to be brought to the Uganda railway, and then carried a long way by rail. He also thought that difficulty was experienced in obtaining fuel for the ginning engines. He believed cotton could not be grown with advantage more than fifty or sixty miles from a good road or railway, as it was very heavy for men to carry. He would also like to know whether cotton was injured by too much or too little rain.

Sir Frederic M. Hodgson, K.C.M.G., said he was Governor of Barbados at the time when the British Cotton-Growing Association began its work there, and when Sir Daniel Morris was in charge of the Agricultural Department of the West Indies. The cultivation of cotton was carried on in Barbados at the time of the cotton famine in Lancashire, and the Association, with the valuable assistance of Sir Daniel Morris, did a great deal to re-establish the industry, which was now in as flourishing a condition as was possible considering the short time that had elapsed since its re-establishment. No doubt the planters there would find it to their advantage to carry on other industries as well, as was the case in Barbados and in British Guiana. In the latter country, of which he was Governor for seven years, the people found it more advantageous to cultivate rice, and the cotton industry was not so successful, although whilst he was there the Department of Agriculture established experimental stations and tried to turn the attention of planters to cotton-growing. He agreed with the author that it was a black man's industry and should be left to black men as much as possible. In the same way the cocoa industry in the Gold Coast had been left in their hands, and had made extraordinary progress, largely on that account. With regard to the credit required in the cultivation of cotton, more especially in West Africa, he hoped it would be possible to establish in that country, and in all tropical countries where black men were to be found, what were known in this country as Co-operative Credit Banks. He tried very hard to form such banks in British Guiana, and believed they had been established since he had left the country. They had, of course, to be under the direct supervision of the Government. When he was in British Guiana the following plan was adopted for enabling the natives to improve the cotton they were growing. Cotton-seed of a good quality was sown along the sides of the roads, and when it grew up the natives, as was anticipated, stole it, and took away the seeds to plant for themselves. In one of the prisons a native prisoner was supplied with a loom to weave cotton cloths, a specimen of which was in his (the speaker's) possession.

Mr. John H. Harris thought something might be done to educate the native producers in the advantages of cotton-growing. He had discussed the question with many natives in West Africa and South Africa, and found they had very little knowledge of the work of the British Cotton-Growing Association. A few months ago he met a white man in the Orange Free State who said he wished to grow cotton, but did not know where he could obtain the seed. Fortunately he (the speaker) was able to give him the address of the Association. He would like to ask the author whether the Association could not use the educational organisations in the African colonies, in order to spread a knowledge of its work and of the great advantages the African producer might obtain from the cultivation of cotton. If the missionary societies and Government schools would occasionally offer a prize for a paper on cotton-growing, that might materially assist in the spread of knowledge concerning that industry, and possibly lead young men later on to devote themselves to scientific study of the subject.

Mr. Alfred Machen referred to the wonderful results which had been achieved in cotton-growing at Kew Gardens with the aid of Professor Bottomley's Humogen, or bacterialised peat, and was sure the British Cotton-Growing Association would be supplied with some of that material for testing purposes if they cared to apply for it.

The Chairman, replying to some of the questions that had been asked in the course of the discussion, said that with regard to the origin of cotton there were many different varieties found in various parts of the world in a wild state. Sea Island cotton was no doubt once a wild plant found in the Barbados. In reply to the question as to whether cotton was an annual or a perennial, it was really a perennial; but the best kinds, such as Sea Island cotton, Egyptian cotton, and the long-staple cotton in the United States, were cultivated as annuals. In some parts of the world, when the crop had been taken off, the heads of the plants were cut off, the stumps being left in the ground. When the rains came again in the following year shoots grew up from the stumps, and in that way a crop could be obtained and the process could be adopted for two or three years.

Mr. J. Arthur Hutton, in replying to the discussion, said that cotton was an article of high value, and could therefore stand a considerable amount of money being spent on its carriage. A gas-engine for ginning had been invented and brought to a state of perfection, the fuel for which was produced entirely from the cotton-seed itself.

Cotton had been grown in West Africa for over a century, and in Northern Nigeria there was a big cotton industry being carried on at the present time. England used to obtain cotton from the West Indies about a hundred years ago, so it seemed rather an irony of fate that English people should now have to go and re-establish the industry there. The Council of the British Cotton-Growing Association had been very much impressed by the idea that the cultivation of cotton was a black man's industry, and there was only one way to induce him to carry on that industry—*i.e.*, to make it profitable for him to do so. With regard to Professor Bottomley's work, the Association was most grateful for the offer that had been made and would be very glad to consider the matter.

On the proposition of the CHAIRMAN, a hearty vote of thanks was accorded to Mr. Hutton for his interesting paper, and the meeting terminated.

"ENGLISH AND GERMAN METHODS CONTRASTED."*

By SIR ROBERT A. HADFIELD, D.Sc., F.R.S.

I should like to bear testimony to the very valuable nature of Dr. Dugald Clerk's recent and most interesting address, and as you are good enough to invite me to add a few comments I have much pleasure in doing so.

In January last (1915) Sir Philip Magnus contributed a letter to the *Morning Post* in reference to certain Jeremiads which had appeared with regard to the uncalled-for remarks by one of our public men who surely should have known better. Lord Haldane made the remark that we in this country "have been behindhand in the application of science to industry, and that we should be better off to-day if we had put anything like that devotion to the task of applying science to industry which has been notable on the Continent."

As Sir Philip Magnus pointed out in his reference to Lord Haldane's remarks, the fact that England was not so well off when the war broke out, or for some time afterwards, was not due to any absence of seriousness on our part "in regard to education," but to other causes. He also said: "Lord Haldane never loses an opportunity of contrasting unfavourably our scientific education with that of other countries, particularly of Germany. There is no lack of men in this country, trained at our universities and technical schools, who are capable of applying the most recent results of scientific research to industrial problems, including the manufacture of implements of war and artificial dye-stuffs. For the economic success of their efforts the encouragement of the State was alone needed." With these remarks of Sir Philip I most heartily agree, and the statements in Dr. Clerk's excellent address bear out this conclusion.

In correspondence between Sir Philip Magnus and myself he was good enough to say that certain testimony I sent him, such as that to which I now refer, should go a long way to shatter the German idol of scientific superiority so long worshipped in this country. He added that he had done his best, both in the House of Commons and on many platforms, to show that German education, reviewed as a whole, and tested by its capacity of turning out men of general intelligence and high moral character, is decidedly inferior to our own, which testimony is referred to in the next paragraphs.

On this question possibly a few words of personal experience are more valuable than theoretical considerations. In my own line of research work, the science of metallurgy, I can, after long experience, truthfully say that to the best of my knowledge we have never been indebted to Germany for a single basic principle. At my company's works in Sheffield, with some twelve thousand men at work, and where most of my research work, extending over thirty years, has been carried out, I am not aware that we have any German process or apparatus in use. I believe that we have still some German beakers in our laboratory, but I am glad to think that they are now being replaced by English-made glassware.

The results of these researches have been embodied in some sixty or more papers and contributions to the Royal Society, Iron and Steel Institute, the Civil, Mechanical, and Electrical Engineers, and many other scientific and technical bodies. The research work done has thus not been selfishly kept in our own laboratories, but the knowledge obtained has been in due time made generally available.

As regards the discoveries and inventions effected and there described, manganese steel, low hysteresis steel, also many other special alloy steels, have now been adopted throughout the world since my first iron-manganese alloy paper was presented in 1888, which was practically the beginning and origination of this particular branch of investigation; in fact, many of these inventions have been adopted by Germany herself. I cannot recollect a single instance in which I have been indebted for basic principles to Germany—not, of course, that I have not appreciated their energy, perseverance, and devotion to science; but this can also be said of other nations, including our own.

American and Continental writers have been good enough to say that my first research in manganese steel was not only important, but was, to use the words of Osmond, the leading French metallurgist, "a discovery which ranked equally in importance to that of the effect of quenching carbon steel, and was the only one of the same order which it had been reserved for our age to make."

* This communication, which was despatched on December 11th, 1915, was delayed in transmission, and has only just been received.—ED.

In respect to scientific progress in metallurgy, we in this country admit that we are much indebted to France, but not to Germany. I would refer to one instance specially, namely, the wonderful and painstaking work of Professor Henri Le Chatelier, who, by his researches, has enabled us to carry out wonderfully accurate measurement of high temperatures. It may, too, be added, and must not be forgotten, that Wedgwood, an Englishman, was several generations ago one of the leaders of research in this direction. Later, Professor Callendar has added greatly to our knowledge; also Dr. Whipple, of Cambridge—all of them obviously not Germans.

As the readers of our *Journal* know, an excellent paper on this subject was contributed to our Society a few months ago by Mr. Chas. R. Darling, entitled "Recent Progress in Pyrometry," from which it would be seen that little, if any, credit on this matter could be claimed by Germany. In other words, they have rather utilised British, French, and American investigations.

I would here like to refer to a very excellent pamphlet, entitled "La Science de Civilisés et la Science Allemand," recently published by Monsieur P. Achalme. It deserves to be read by every scientific man, and I hope some translation will make its excellent conclusions more widely known in this country, showing, as the pamphlet does, that Germany has been very much overrated in the world of science. The Hun has applied and copied from others, but not originated.

The Bessemer process, from which Germany has derived so much benefit, was certainly not invented there. The discovery of the basic steel process, as is well known, was also due to our chemists, Thomas, Gilchrist, and Snelus, and to M. Pierre Martin, in France. It is to this process that Germany is largely—in fact, chiefly—indebted for its developments in the production of cheap steel. Moreover, Germany obtained most of her ideas about metallurgical plants from the streams of Germans who visited our cousins over the water to pick up, and not improperly so, all the information they could whilst America was developing her steel industry. Still that was not origination; it was copying.

As an engineering point it may be interesting to note that a great deal of the German export business has been developed by bounties, for example, amounting to as much as 30*s.* per ton of steel rails. Imagine what it would have been if the metallurgical industry of this country had been supported by such enormous bounties. I am not speaking of the rights and wrongs of such a policy of bounty, but it is unfair conditions of this kind which have largely enabled Germany to fight us, including, for example, the misuse by Germans of patents in Great Britain.

A very shrewd and naturalised German in this country told me long before the war that until we made up our minds to stop this unfair competition our iron and steel industries were bound to suffer, and could not make progress in the direction of much larger production.

Personally, I may say that Krupp has worked a number of my own patents; so evidently he did not consider that he possessed all the metallurgical wisdom in the world.

The late Dr. Geheimrath Wedding, of Berlin, was good enough to say, when he visited my company's laboratories at our works in Sheffield in 1905, during the Iron and Steel Institute meeting there, that "the research laboratory of the Hadfield works is of a completeness which would serve as an example to every academy in Germany."

I believe, therefore, that I shall have every Englishman with me when I say that the Jeremiads of Lord Haldane and others are thus not only foolish and incorrect, but are most unpatriotic. It has been, therefore, with unusual pleasure that I have read the courageous and perfectly accurate address by Dr. Clerk on November 17th.

In saying this I see no reason not to add that, like many Englishmen, I have received the utmost kindness and courtesy during my trips to Germany. Whilst fully recognising the hard work and perseverance of the Teuton, nevertheless I have never met in this nationality anything which seemed to show the superiority about which some of those in our country seem to have had a mania for continually expressing their admiration, with its consequent great harm.

I have not the slightest wish in making this remark to depreciate the excellent work of German scientists. It has been a sad sight to see so many friends in the world of science in that country uttering sentiments that, but a few years ago, they themselves would have been astounded to imagine they could ever utter; and to read, as our then head of the Royal Society, Sir William Crookes, of whom we are so proud, pointed out in his anniversary address, that such a man of eminence as Dr. Philipp Lenard, Professor of Physics at Heidelberg, made the following savage outburst: "Down, then, with all considerations for England's so-called culture. The central nest and supreme academy for all hypocrisy in the world, which is on the Thames, must be destroyed if the work is to be done thoroughly. No respect for the tombstones of Shakespeare, Newton, and Faraday!" We English can never forget such desecration of the use of language. The psychology of mind of one—a scientific man, trained in science—who could descend to such depths is hard to understand. During the whole of this terrible crisis in human affairs I cannot remember ever having heard a single bitter word uttered by Englishmen in regard to Germans of the eminence of Goethe, Schiller, Wagner, and others.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Exports in War Time.—The dependence of the textile trades upon the export markets is traditional, and it is of a certain interest to note how their goods have fared, relatively to all others, in the general fall recorded in the returns for last year. In 1913, when exports of British manufactures were £411,000,000, textiles and apparel formed 48 per cent. of the whole. Last year, when the total was down to £292,000,000, textiles and apparel formed a proportion of substantially 50 per cent. It should be of some consolation to know that the relative position is no worse. A point that takes the eye in a general survey of the details of the export trade is the smallness of the loss in direct trading with the hostile countries. Measured in yards the shortage of the exports of cotton piece goods is 2,327,000,000, in comparison with 1913. A trifle over 3 per cent. is all that is ascribable directly to the stoppage of sendings to Germany, and although there are 350,000,000 yards less to Turkey, even this item is small. The reduction of 1,150,000,000 to India and of 341,000,000 to China, and the all-round decreases to the South American markets are appreciably more to the point. Where, as in the case of worsted yarn, the cessation of German buying would seem superficially of great effect, the simple fact is that in the prevailing conditions the absence has not been missed.

A Substitute for Acid.—It is perhaps a tribute to the economy of the previous management to say that the war has disclosed remarkably few opportunities of substituting waste products for supplies that have grown unwontedly scarce and dear. Under stronger pressure it is conceivable that more of the second-best might have been brought within the range of practice, and the absence of striking instances cannot be altogether a matter of regret. The absorption of sulphuric acid by the munitions factories has accounted already for a rise to three or four times the accustomed price of brown oil of vitriol, and the commodity promises only to become more scarce. Those who have used sulphuric in dyeing and bleaching, the carbonisation of rags, and the recovery of grease from washing waters, are under the obligation therefore of considering anything that can be used in its place. An alternative to fluid acid has been found in the spoil heaps of the nitric acid maker, whose nitre cake remaining after the treatment of Chile saltpetre becomes a nuisance to himself. The cake contains 30 per cent. of sulphuric acid, and is a dripping mass inconvenient of transport and more difficult of handling than common vitriol. The material has, however, been satisfactorily substituted, and is capable of use upon a larger scale, granted that certain steps to organise its supply and distribution are taken. These measures have the attention of the Ministry of Munitions and of committees of consumers, and it is altogether probable that nitre cake will be brought into more general consumption.

The Fly-shuttle.—It was in 1733 that John Kay, of Bury, obtained his patent for the fly-shuttle propelled by a jerk across the loom in place of the instrument that had to be thrown across by hand. The invention liberated one of the weaver's hands, accelerating progress by giving him time to beat home the reed, and the picker is incorporated, of course, in the power loom. It must give some people a shock to realise that there are still parts of the world in which this improvement is imperfectly appreciated and not universally adopted. With a view to securing a wider recognition of an improvement which is no secret and not in doubt, the Government Weaving Institute at Benares has been arranging a series of public demonstrations for the conviction of the hereditary weavers in the United Provinces. Matches between local weavers and students using the fly-shuttle have been held, with the effect that they have been shown that wider cloth can be woven, that three to four times the length can be produced, and that yarns as fine or finer can be used. These arguments may be thought insuperable, and the conversion of local opinion should follow as a matter of course. The fly-shuttle has been seen beforehand in the same quarter, but for the reason that in the schools the looms were worked upon two-fold warps the suspicion had spread abroad that they were useless upon any other.

The Dislocation of Transport.—The disorganisation of inland transport is responsible for a strain upon working capital of which little has been heard, and, coming upon the top of inflated prices, the inconvenience is serious. The case is perhaps seen at its worst in respect of wool. One pound of raw wool costs as much as two pounds used to do, so that for a beginning a buyer has to find twice the money. The wool has to be paid for within a stipulated limit of time and before it can be touched. When the material is wanted it cannot be had because of the congestion of docks and railways, and the owner has to go forth and buy more, often at still higher prices, to meet his pressing obligations in delivery. More or less throughout the whole course of manufacturing there are delays arising out of the non-delivery of one article or another, and when the goods are manufactured there is at least twice the usual delay in getting them dyed and receiving payment. The necessity of keeping twice the usual stock in progress redoubles the need of money, and even the most cautious and thrifty of managers have been reduced to unknown straits in financing their transactions. The instance is only another one

displaying the effects of a ramrod introduced into the vitals of the complex machinery of commerce. All transport is disarranged, and that which most concerns manufacturers at present is the carriage of coal. Industrial consumers are paying double prices for engine coal, and are feeling that on these handsome terms they ought at least to be privileged to receive enough for their daily needs. The output from the pits has been lowered by recruitment, the munitions factories have first call on the supply, and the available balance is out of reach for want of trucks or sidings or, as some say, rational organisation of the existing facilities. Now, more than ever, manufacturers appreciate the relief that their own motor-waggons give.

Specifications for Fabrics.—Army-contracting should have done something to break down the almost invincible prejudice against working to precise specifications. It has always been obligatory to work to specified lengths, widths, and weights, but not to definite strengths, and manufacturers have been disposed to look upon guaranteed breaking-strains as devices to entrap them. The breaking-strain determined by a direct pull exerted between pairs of vice-jaws is not exactly equivalent to wearing-strength, although there is some relation between the figures. What manufacturers have preferred to do has been to quote to a pattern, treating strength as a factor variable for causes not all within their control, and relying on giving good, merchantable durability. They have not, in their ordinary trading, regularly tested and recorded the strengths of their goods, and thus have not known with particularity how the facts stand. Their experience has suggested to them that those who insist upon a guarantee pitch their standards at a height which cannot unfailingly be reached. The objection is not so much to standards as to unfair standards, and more light has been thrown upon the whole matter of cloth strengths in course of prolonged efforts to satisfy official requirements. The testing machine reveals the use of deficient raw material, and if this is of disadvantage to some it is not so to others who may be undercut in competition. Granting always that the standard fixed is one that can reasonably and consistently be maintained, there is something to be said for its existence. Deficient raw material may reveal itself to the practised eye, but not all buyers of fabrics, and certainly not all who buy on account of public institutions, are skilled in the detection of minute differences of quality.

Worsted in Japan.—It appears from the report of a well-informed correspondent of the *Far East* that extensions are afoot in the worsted industry of Japan. The present woolcombing equipment of that country is far inferior to that which can be found in many a single shed in Yorkshire. There are at present fifty-two combs, and their number should be doubled by the middle of the year. Within two years it is anticipated that Japan will be independent of all outside combers and nearly independent also of outside sources of worsted yarn. The present number of worsted spindles in Japan is the small one of 155,000, and of woollen spindles 55,000. The worsted trade has been confined to the making of *mousseline de laine*, a business that has been overdone, and that does not offer the opportunity of expansion afforded by trades which are probably no more difficult to negotiate. Japan lacks, however, the heavier looms that would be required for making general worsted fabrics.

Mill Property in France.—Where, as at Rheims, textile mills in France chance to be on the firing line the devastation of premises and machinery is complete. A consensus of private messages shows that mills within the occupied territory have at least not been torn down by the enemy. In Roubaix a couple of mills have been kept running on German Government work, and the remainder are at a standstill. The plants have been systematically rummaged for copper, brass, rubber and leather, and parts of machinery made from any of these materials have been removed into Germany. It is recorded in one case that the very pickers and straps have been taken from the looms, and in a large mill the depredations have been on a scale leading the proprietors to estimate that a good nine months would be required to restore the place to working order. The chance of a more sweeping destruction remains, and in point of disablement there is little to choose between the dismantling and outright wrecking.

GENERAL NOTES.

Sericulture in France.—The following figures, lately published in the *Journal Officiel*, show a notable decrease in the production of raw silk in France since the outbreak of the war:—

	1913.	1914.	1915.
Total number of silkworm-rearers	90,517	83,825	43,327
Quantity of "seed" (eggs) incubated, in ounces of 25 grams each*	125,678	108,943	49,182
Production of cocoons (unstoved) in kilogrammes	4,423,046	5,067,392	1,727,326
Ditto, in English lbs.	9,752,816	11,173,539	3,806,784
Value in francs	15,655,016	19,908,930	4,243,027
Ditto £ sterling	626,200	796,357	169,721

It must be observed that the silk harvest of 1914 was completed at least a month before war was declared.

Demand for Walnut Leaves in France.—There appears to be some demand for the dried leaves of the walnut tree in France at the present time. They are used largely for pharmaceutical purposes, and previous to the war were

* The ounce of 25 grams = 385·81 English grains.

supplied chiefly from the Department of Aisne, now occupied by the Germans. They are now obtained from other countries. The leaves, which should preserve their green colour when dried, are worth from 60 francs to 70 francs per quintal (from 24*s.* 6*d.* to 28*s.* 6*d.* per English cwt.).

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m. :—

February 2. — The Hon. Lady Parsons, "Women's Work during and after the War." Dugald Clerk, D.Sc., F.R.S., Chairman of the Council, will preside.

February 9.—Professor J. A. Fleming, M.A., D.Sc., F.R.S., "The Organisation of Scientific Research." Dugald Clerk, D.Sc., F.R.S., Chairman of the Council, will preside.

February 16. — S. Charles Phillips, M.S.C.I., "Paper Supplies as affected by the War." Lord Burnham will preside.

February 23.—Miss H. B. Hanson, M.D., B.S., D.P.H., "Serbia as seen by a Red Cross Worker."

March 1.—Charles Delchevalerie, "Belgian Literature."

March 8.—Charles R. Darling, A.R.C.Sc.I., F.I.C., "Optical Appliances in Warfare."

Indian Section.

February 17.—C. A. Kincaid, C.V.O., Indian Civil Service (author of "Deccan Nursery Tales," "The Indian Heroes," "The Tale of a Tulsi Plant," etc.), "The Saints of Pandharpur: the Dawn of the Maratha Power." Lieut.-Colonel Sir David W. K. Barr, K.C.S.I., will preside.

March 16.—Professor Wyndham R. Dunstan, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India."

Dates to be hereafter announced :—

R. W. Seton-Watson, D.Litt., "The Balkan Problem."

Rev. P. H. Ditchfield, "The England of Shakespeare."

W. A. Craigie, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

Victor Horta, Directeur de l'Académie Royale des Beaux-Arts de la Ville de Bruxelles, "Belgian Architecture."

Professor T. G. Masaryk, "The Slavonic Peoples."

G. P. Baker, "Hindu Hand-painted Calicoes of the Seventeenth and Eighteenth Centuries, and their Influence on the Tinctorial Arts of Europe."

Edward Percy Stebbing, F.L.S., F.R.G.S., Head of the Department of Forestry, University of Edinburgh, "Forestry and the War."

Sir Daniel Morris, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland."

James MacKenna, M.A., I.C.S. (Deputy Commissioner, Myaungmya, Burma, and designated Agricultural Adviser to the Government of India), "Scientific Agriculture in India."

Indian Section.

Thursday afternoons at 4.30 p.m. :—

April 6, May 18.

Colonial Section.

Tuesday afternoons, at 4.30 p.m. :—

March 21, April 11, May 2.

Cantor Lectures.

Monday afternoons at 4.30 p.m. :—

J. Erskine-Murray, D.Sc., F.R.S.E., M.I.E.E., "Vibrations, Waves, and Resonance." Four Lectures.

May 1, 8, 15, 22.

Fothergill Lectures.

Monday afternoons, at 4.30 p.m. :—

Rev. Dr. Herbert West, D.D., A.R.I.B.A. (author of "Gothic Architecture in England and France"), "National and Historic Buildings in the War Zone: their Beauty and their Ruin." Three Lectures.

Syllabus.

Lecture I.—February 7.—*Belgian Architecture and History.* Belgium a land of cities—What makes a city (Gen. xi. 4)—Tower—Church—Communal Hall—Belgian civil architecture, commercial—Cloth Halls before Town Halls—Churches borrowed, but splendid furniture given by Trade Guilds. Ypres typical — Tournai. Rhenish. Source of Noyon—Soissons. St. Remi—French efforts to annex Flanders—The Matins of Bruges—Battle of the Spurs. Courtrai—Rivalry of Ghent and Bruges—Edward III. and J. van Artevelde—Sluys—Coucy. Pierrefonds—Mediæval sieges—Philip van Artevelde, Roosebek. Suzerainty of Burgundy—Charles the Rash and Louis XI. Dinant—Sack of Liége. Mary of Burgundy. Arras—Lierre. Charles V. and Philip II. Egmont and Horn—Louvain—Malines—Antwerp—Louis XIV. and William III. Namur. Bombardment of Brussels.

Lecture II.—February 14.—*Gothic Architecture, French and English.* The French Cathedral, a Great Hall, the centre of the city's life. The English Cathedral a Monastic Missionary settlement, independent of the city. The problem of

Mediæval Architecture, to reproduce Roman vaulting—Solved by permanent stone centrings (diagonal ribs) under the intersections of a groined vault (Vezelay, Durham, St. Denis, Sens). Buttresses necessary (Chartres, Amiens, Beauvais). The walls become screens of glass. Inside—Columns replaced by vaulting ribs running down to the ground (Notre Dame—N. D. de l'Épine, Abbeville). Contrast of French and English plans (Notre Dame and Salisbury). In the English Cathedral, horizontal, not vertical perspective sought. Beauty of clustered columns. Purbeck causes deep mouldings. Multiplication of vaulting ribs. Lierne and fan vaulting—Flamboyant and perpendicular—English and French façades—The French Cathedral is the expression of the National ideal; the English, of the National history.

LECTURE III.—FEBRUARY 21.—*French Mediæval Sculpture.* Christian art that of a new-born society rising amidst a dying civilisation—Provençal sculpture, Arles, etc., decadent—Burgundian, full of life and imagination; but Classical influence traceable all through (Vezelay, Autun, Auxerre)—XIIth Century (Avallon, Bourges, N. and S. doors, Chartres, W. front). Elongation of statues, architectural not ignorant—Individual types, elaborate detail. The sculpture scheme of a XIIIth Century cathedral (Laon, Notre Dame, Amiens, Reims). The Judgment door (Autun, Notre Dame, Amiens, Rampillon, Reims, St. Maclou)—The Virgin's door—Local Saints and legends (St. John Baptist, Rouen; St. Stephen, St. Théophile, Paris; St. Thomas, Semur; St. Nicaise, Reims)—The Arts, Virtues and Vices—The Months and Daily Life (Paris, Amiens, Rouen)—Statuary (St. Stephen, Sens—The Virgin, Paris—Chartres, N. and S. porches)—Reims, W. portals—Figures of Christ (Chartres, Amiens, Reims, Troyes, Solesmes).

The lectures will be illustrated by lantern-slides.

EDWARD A. REEVES, F.R.A.S., Map Curator, Royal Geographical Society, "Surveying." Three Lectures.

March 27, April 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 31...British Architects, Royal Institute of, 9, Conduit-street, W., 3 p.m.

TUESDAY, FEBRUARY 1...Royal Institution, Albemarle-street, W., 3 p.m. Professor C. S. Sherrington, "The Physiology of Anger and Fear." (Lecture III.)

Alpine Club, 23, Savile-row, W., 8.30 p.m. Mr. E. A. Broome, "Zermatt in Wartime."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Mr. E. Marriage, "First Steps in Photography with the Microscope."

Rontgen Society, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8.15 p.m. Exhibition of Lantern Views of Gallipoli.

WEDNESDAY, FEBRUARY 2...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. The Hon. Lady Parsons, "Women's Work during and after the War."

University of London, King's College, Strand, W.C., 5.15 p.m. Mr. Sidney Low, "The War and the Problems of Empire." (Lecture I.)

Geological Society, Burlington House, W., 8 p.m.

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m. 1. Annual General Meeting. 2. Mr. G. D. Elsdon, "Note on Human Milk." 3. Mr. W. T. Burgess, "Notes on Common Processes used in Water Analysis." 4. Messrs. J. H. Barnes and Arjan Singh, "Poli Oil—a New Adulterant of Ghee."

Sanitary Engineers, Institute of, Caxton Hall, Westminster, S.W., 7 p.m. Professor G. J. Fowler, "The Activated Sludge Process of Sewage Purification."

Entomological Society, 11, Chandos-street, W., 8 p.m.

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. P. M. Johnston, "Wall-Paintings in Arundel Church, Sussex, compared with similar contemporary Examples."

Medicine, Royal Society of, 1, Wimpole-street, W. Surgery Section, 5.30 p.m. Dr. F. Hernaman-Johnson, "The Use of Condensers in the Diagnosis, Prognosis, and Treatment of Nerve Lesions."

Ophthalmology Section, 8.30 p.m. 1. The late Mr. George Coats (to be read by Mr. R. Affleck Greeves), "The Cause of the Ophthalmoscopic Appearances in Amaurotic Family Idiocy." 2. Mr. H. Spicer, "Superficial Linear Keratitis." 3. Mr. W. Edmunds, "Cataract in Experimental Thyroidectomy."

THURSDAY, FEBRUARY 3...Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Chemical Society, Burlington House, W., 8 p.m. Professor W. H. Bragg, "The Recent Work on X-Rays and Crystals and its bearing on Chemistry."

Royal Institution, Albemarle-street, W., 3 p.m. Professor W. A. Bone, "The Utilisation of Energy from Coal: Industrial Applications of Gaseous Fuels derived from Coal." (Lecture III.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. F. Martin Duncan, "Nature's Masonry and Nature's Ruins."

Medicine, Royal Society of, 1, Wimpole-street, W. Obstetrics and Gynæcology Section, 8 p.m. 1. Dr. W. Salisbury, "Three Cases of Labour obstructed by Ovarian Cyst." 2. Dr. F. M. Huxley, "Fatal Rupture of Bladder in the Puerperium." 3. Dr. M. Handfield-Jones (President), "Chorion Epithelioma following Vesicular Mole." 4. Dr. M. Handfield-Jones, "Clinical Aspect of the Double Uterus."

FRIDAY, FEBRUARY 4...Royal Institution, Albemarle-street, W., 9 p.m. Professor W. Bateson, "Fifteen Years of Mendelism."

University of London, Bedford College, York-gate, N.W., 5 p.m. Mrs. M. Creighton, "The State and the Church."

Geologists' Association, University College, W.C., 7.30 p.m.

Medicine, Royal Society of, 1, Wimpole-street, W. Laryngology Section, 4 p.m.

Economics and Political Science, London School of, Clare-market, W.C., 5 p.m. Sir George Paish, "The Economic Strength of Great Britain."

SATURDAY, FEBRUARY 5...Royal Institution, Albemarle-street, W., 3 p.m. Sir Sidney Lee, "The Shakespeare Tercentary: The Range of Shakespeare's Influence." (Lecture I.)

Journal of the Royal Society of Arts.

No. 3,298. VOL. LXIV.

FRIDAY, FEBRUARY 4, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

NEXT WEEK.

MONDAY, FEBRUARY 7th, 4.30 p.m. (Fothergill Lecture.) REV. DR. HERBERT WEST, D.D., A.R.I.B.A. (author of "Gothic Architecture in England and France"), "National and Historic Buildings in the War Zone: their Beauty and their Ruin." (Lecture I.)

WEDNESDAY, FEBRUARY 9th, 4.30 p.m. (Ordinary Meeting.) PROFESSOR J. A. FLEMING, M.A., D.Sc., F.R.S., "The Organisation of Scientific Research." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

PROCEEDINGS OF THE SOCIETY.

EIGHTH ORDINARY MEETING.

Wednesday, February 2nd, 1916; DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, in the chair.

The following candidates were balloted for and duly elected Fellows of the Society :—

Aiken, Rev. James, M.A., St. Thomas' Manse, Georgetown, Demerara, British Guiana.

Briefer, Michael, Ausco Company Research Laboratory, Binghampton, New York, U.S.A.

Brooks, Edmund D., 89, Tenth-street South, Minneapolis, Minnesota, U.S.A.

Griggs, Professor Edward Howard, A.M., Montclair, New Jersey, U.S.A.

Hemmeter, John C., M.D., Ph.D., Sc.D., LL.D., 739, University Parkway (Roland Park), Baltimore, Maryland, U.S.A.

Howell, Hon. Clark, Atlanta, Georgia, U.S.A.

Lawrence, Thomas Richard, 5, Bellasis-road, Byculla, Bombay, India.

Monserrat, Nicholas D., Hartman Building, Columbus, Ohio, U.S.A.

Randolph Isham, D. E., 1827, Continental and Commercial National Bank Building, Chicago, Illinois, U.S.A.

Ridge, James A., The Ceylon Wharfage Co., Ltd., Colombo, Ceylon.

Sibert, General William L., Presidio, San Francisco, California, U.S.A.

Thorndike, Townsend William, M.D., 20, Newbury-street, Boston, Mass., U.S.A.

Updike, Daniel Berkeley, The Merrymount Press, 232, Summer-street, Boston, Mass., U.S.A.

THE CHAIRMAN, in introducing Lady Parsons, took it for granted that those present at the meeting were all familiar with the work of her distinguished husband, Sir Charles Parsons, in the development of the steam turbine, a work which had benefited the whole world and Great Britain in particular. Lady Parsons had given special attention to the question of women's work in war.

The paper read was—

WOMEN'S WORK DURING AND AFTER THE WAR.

By THE HON. LADY PARSONS.

The title of the paper before us, "Women's Work during and after the War," covers a very wide field. I propose to narrow it down somewhat, and speak chiefly on the work of educated women—taking, first, voluntary work, then the principal professions open to women; and, finally, some suggestions for the more extensive employment of women's brains in developing the resources of the country.

The first weeks of the war saw a great rush of women from the upper and middle classes eager to offer their services for any kind of

work, if only they might have something useful to do.

With a quick grasp of the possibilities of so much service willingly offered, Her Majesty the Queen came forward and initiated well thought-out schemes for employing all the women of England on making clothing urgently needed for our rapidly increasing armies, and for supplying hospitals with the comforts and necessities they would soon be needing for our wounded sailors and soldiers.

Other work guilds and societies followed suit, and covered distant localities that could not have been reached by one central organisation, and so well did Her Majesty's idea catch on that a steady stream of clothing kept pouring into all the depots, collected from every part of the United Kingdom.

A later development of working guilds and societies, showing a further advance along the road to efficiency and systematic supply, are the war hospital depots in London and the provinces. In the fine old Georgian mansion, kindly lent by King's College for Women, and in six other houses, some three thousand ladies are at work, and turn out each week about twenty thousand surgical dressings and other articles.

In one room some fifty ladies are making surgical swabs, using a very ingenious little machine for teazing the raw material invented by one of their number. In another room they are rolling bandages, using the latest improvement in bandage roller, also perfected on the premises; others are making hospital requisites from old linen and soft materials, sent in as gifts. Upstairs are the sterilising rooms, and in another room the articles are being packed with the neatness and precision of the professional packer. In another house all sorts of clothing are being made, to standard patterns, two rooms being devoted to the making of carpet slippers. There are, in addition, carpentering shops where are being turned out the best of splints, crutches, bed tables and rests; but this work is carried on by some hundred men over military age, who make about six hundred articles a week of a unique and well finished character invaluable to hospitals.

The interesting feature about these voluntary workrooms is that the workers are actually setting up a standard of excellence for their surgical articles; there is nothing at all of the amateur about the work, all is to standard patterns and can be repeated, and is of the best workmanship.

The extremely business-like management of these depots, and the high standard of the work produced in them, suggest the lines on which a women's factory, run by women for women, might be carried out on economic lines.

In the working-classes, one of the first effects of the war was, unhappily, the displacement of women's labour; most of the small luxury trades, such as florists, milliners, fancy stationers, confectioners and small dressmakers, either closed their businesses altogether or employed a fewer number of hands.

It was objected that all the guilds and work societies were taking the bread out of poor women's mouths, and that independent women ought to have employed their poorer sisters instead of working themselves. This did not seem to be a very sound argument, as, if carried to its logical end, there would not be any voluntary work at all, and the women of the so-called leisured classes, full of energy and very excellent business capacity, would have to sit in idleness and waste their brains in the unprofitable study of how to do nothing.

Happily after a few months of uncertainty, work became plentiful and well paid, and any temporary distress was absorbed in the general prosperity of the wage-earning classes.

Attracted by the stirring outdoor life and the movement and change, hundreds of healthy young girls are taking the place of boys as messengers, telegraph and errand girls. They ride on vans and deliver parcels, and sometimes drive the vans themselves; they conduct trams and drive taxis; they mount ladders and clean windows and street lamps; they punch your tickets and carry your luggage. That many of these occupations are blind alleys does not disturb the joyful young spirits, who find them an easy and congenial task, and, escaped from dressmaker's workrooms, will not be easily shut up again in these respectable sanctuaries.

Medical.

Coming to the professions for women that the war has brought into special prominence, the medical profession stands out clearly as the highest and most important of the professions, so far, open to women. Never before have women doctors had such opportunities for distinction and such a wide scope for their skill, and very splendidly they are responding to the calls of service.

Here in London a women's military hospital, with five hundred and fifty beds, has been at work since May. It is established in the old

workhouse (now no longer needed) of Endell Street, completely remodelled and brought up to the requirements of a modern hospital. The whole of the administrative staff are women. The medical staff consists of fourteen women, and comprises all the specialists proper to a hospital of this size. Being a military hospital they rank, for purposes of pay, from a major to a subaltern. All the surgical operations needed for the wounded soldiers are done in the hospital by the women surgeons. The hospital is under exactly the same inspection, and no other, as any of the other military hospitals.

Certain pleasing touches show the great interest taken by professional women in this, the first military hospital to be staffed by women. Such, for instance, is a very complete library for the use of the patients and general staff. Some of our favourite authoresses give their services as librarians, and personally advise the patients in the books most likely to please; and many of the most popular actresses in London form the committee of the entertainments.

Medical women are able to specialise in the different branches of surgery or medicine that most appeal to them. One may prefer research work, another may be successful in the treatment of nervous complaints. Some few women are specialising in the several branches of X-ray work. This needs a further and varied training. The operator must have a practical knowledge of electricity to put up and keep in order the apparatus; and she must be a good photographer to understand and develop the shadowy negatives. One medical woman, who has spent her life in the most accurate scientific observation, is able to localise a piece of metal to its exact depth and position in the wound; she is able to tell the surgeon whether the bullet is accessible or not, whether it is in a position where damage may be expected, or whether it may safely be left; and in thus saving many a wounded patient from unnecessary pain she finds a fitting crown to a life spent in unobtrusive study.

The Scottish Women's Units in France have set up a standard of efficiency that completely astonishes the French medical authorities. The large unit at Royammont carries on a fully equipped military hospital under the French Red Cross.

The story of the units in Serbia, and all their hardships and sufferings and their terrible experiences in crossing the mountains, is gradually being related by members who have been lucky enough to arrive home, and makes a thrilling page of history.

It is very remarkable that although French medical women are very highly skilled, and have been admitted to study in all the general hospitals for several years, they have not been allowed, in one single case, to set up as a unit to give medical assistance to their own countrymen. The French medical women are themselves extremely distressed (not unnaturally) at the preference shown to British women surgeons, while they, in their own country, have to accept subordinate positions. The conclusion arrived at between the medical women of the two countries (in friendly conversation) seems to be that the English medical women owe their present better position to the fact of having a medical school entirely managed by themselves, where all the responsible positions, the administration, finance, the lectures, and the entire business of the school are carried on by themselves. Thus they have useful experience, and learn how to deal with people, how to take responsibility, and how to fill important positions.

The status of medical women is greatly strengthened at the outset of their career by having a strong well-established institution behind them, such as the London School of Medicine for Women; an institute that can take up on behalf of the young doctor any professional difficulties that may arise, any trouble as to salary or status, or any of those disputes that are always liable to come up in any profession.

Now that the number of women medical students has increased so largely, it is most essential that the London School of Medicine for Women should be brought thoroughly up to date. It is being enlarged, new laboratories and lecture rooms being essential for the accommodation of all the new students. In the absence of so many medical men called to the service of the army, and so few young men taking up the medical profession at present, the woman doctor is becoming a very real necessity to the country. Although the value of the medical student is prospective rather than present, it would be a great mistake on the part of the public to let the important years of study and clinical practice suffer curtailment for want of adequate support.

Musical and Theatrical.

In pleasant co-operation with the medical women come the artists of the musical and

the theatrical world, equally intent on restoring the soldier to health, vigour, and happiness, though by different methods.

The theatrical concert parties, given under the auspices of the Ladies' Committee of the Y.M.C.A., are playing an important part in the treatment of nerve troubles at the front. The parties go out for a fortnight at a time, they give generally three concerts a day, the concerts always last two and a half hours, and there is never any interval. In the huts of the Y.M.C.A. wherever they are built, in the rest camps of all the area where troops are, in camps of remount men, of ordnance and of motors, in artillery parks, in forage depots; wherever men are suffering from dullness and consequent depression, the concert parties come and cheer them; and in other huts and camps, and in hospitals where men have been recently in the trenches and under shell fire, and cannot throw off the feeling of strain, or forget the sights and sounds they have experienced, the music comes as a peaceful interlude, and often brings back sleep to those who cannot rest.

One hardly needs to comment on the generosity of the artists, because it is thoroughly characteristic of the musical and theatrical world to give freely of their brilliant talents; but it is a kindly and noble work of busy professional women, to undertake all this hard work and personal inconvenience at the minimum of expense.

Nursing.

For general popularity, the nursing profession stands high at the present time. The average man considers this an entirely suitable profession for every woman, and consequently offers no real opposition to a certain amount of training for it. Indeed, it is accepted as an axiom that every woman can nurse the sick, as it is accepted that every man can fight the enemy. In war time the nursing profession is suffused with a special glamour. The vision of giving first aid to soldiers on the actual field of battle rises before our exalted imagination, and fills the mind with vivid pictures of the highest personal sacrifice.

But the fact of the high organisation of our military medical and nursing services prevents the realisation of any such romantic dreams. The magnitude and the horrors of this war, and the immense number of casualties, seemed to the War Office to make it undesirable for the services of women to be used near the fighting lines. In France and Flanders the advanced dressing stations have been the work of the men surgeons and dressers, and the women nurses have worked in the clearing and base hospitals, trains and ships. Only with the armies of some of our smaller but most gallant Allies have nurses had the chance of rendering real first aid. With the Belgian army at the beginning of the war, several parties of women were working close up to the lines, and recently with the indomitable Serbians several of the Women's Units have been the advanced dressing stations.

The training for a nurse in the higher branches of this profession, such as a sister in the Imperial Military Nursing Service, is thorough and methodical. She must have a three years' training in a general hospital and fulfil other qualifications before being accepted for a military hospital. Then she is gazetted into the army, and her name appears in the official Army List.

The Territorial Nursing Service is much younger, but just as thorough and on the same lines as the regular service. With their excellent county organisations, and owing to their splendid routine work, the Territorials were able to complete their mobilisation in a very short time, to call up their three thousand trained nurses, and to organise a large number of auxiliary hospitals.

Their system of training being established, it was comparatively easy to expand, and take in the innumerable trained nurses from civil life who were anxious to give their services as soon as war broke out.

Among amateurs, none have been more quick and ready for service than the Voluntary Aid Detachment of the Red Cross. From the first moment of war, many detachments mobilised, and were ready with emergency hospitals (often improvised out of schoolrooms, to the entire satisfaction of the scholars), they were complete with nursing staff, beds, kitchens, and ambulance, fully equipped and only waiting and anxious for patients.

In the innumerable hospitals that the war has called into being in every corner of Great Britain, educated girls are cheerily doing their best, learning methodical habits, submitting to discipline, and working loyally together, habits that must be useful whatever the future may have in store.

Agriculture and Gardening.

Some considerable attention has been given lately to schemes for the training and employment of more women in agriculture. This world-wide industry varies so much according to local

habits and customs, it is impossible to make any general observations that would be correct for the whole of Great Britain. The agricultural population is rooted to its methods, and views any innovation with horror. One can only safely say that in places where it has always been the custom for women to work in the dairy, the byre and the fields—as in most parts of Northumberland—women are, at the present time, in considerable demand, milkers especially earning good wages. But the women employed hitherto are always of the agricultural class; no more training is required than what they pick up on the farm; hoeing the crops, picking off stones, haymaking and harvesting, are the usual field of operations in the North.

The shepherd on the Cheviot Fells treats with scorn any suggestion for women's help with his arduous duties. The work of dipping several hundreds of sheep and of shearing them, he considers far beyond a woman's strength; but hardest of all is his winter's work. He must make his daily rounds throughout the winter's storms, plunging through the snow-drifts and over frozen pools and see all his flocks collected in some secure fold or natural coombe, safe from the gathering snowstorm. Sometimes he fails, through exhaustion, to reach home, as once last winter, when the shepherd and his dog were found in the morning frozen dead in a snow wreath, the master's coat round the body of his dog.

In the southern counties, several training centres are established for giving courses in various branches of agriculture. It seems to be accepted that the girls who take these courses are from the educated classes; those girls who have been at modern schools, and have learnt all sorts of out-door games and have imbibed a healthy love of fresh air and exercise are the most promising recruits for farm work. The cottager's daughter from the country village prefers to go into a factory and do repeat work.

As gardeners women are earning good opinions. Perhaps the ideal situation for a woman is where she can work as improver under an experienced head gardener, and where the digging and other very heavy work can be done by a labourer. In such a garden she learns thoroughly and very quickly all the mysteries of potting, pricking out, of propagating and sowing seeds, under the best conditions of soil and weather, and the general routine of a good garden.

Another favourite post is as a special rockery gardener; she must dispose the little miniature crags and precipices and lay out the rocky pathways, she must place the stepping-stones to give reality to the little watercourse cunningly brought in by a pipe; then she must make a special study of the capricious tastes in soil and aspect of the fascinating little Alpine gems that love to grow amid these miniature crags, and when she works in the right spirit an educated girl has plenty of scope for her artistic tastes.

Clerical Government Work.

In all Government offices, hundreds of women have been taken on to release young men to join the colours. Girls with a knowledge of several languages, and a general grip of affairs, are employed in such interesting work as censoring, and for indexing and registration. In the War Office and at the Ministry of Munitions, the majority of the clerks now are girls, and at the Admiralty those who have had some training as art students are quick at learning to draw and colour, to enlarge and reduce the innumerable maps and charts required in the Service.

The Board of Trade has recently taken a new departure and appointed a university graduate as chief woman inspector at a high salary. In fact, broadly speaking, university girls are gradually being engaged as forewomen, supervising clerks and inspectors wherever large numbers of women are employed by Government.

Engineering.

A new field for women's enterprise seems likely to develop in the important industrial profession of engineering. In the munition areas new factories are springing up, and old firms are changing their plant and adapting their machines to munition work.

In all of the larger factories thousands of women and girls are employed. In one type of factory the girls are handling the heavy shells, placing them in the lathes, rough turning and centering them; in another shop they are engaged in the slightly more skilled work of engraving. In another factory one hundred girls will be feeding cardboard into machines, to be rolled up into cylinders for star and flash lights. Another hundred will be stamping out metal cartridge-cases in various stages of completion, others will be gauging the cartridge-cases, their nimble fingers moving at lightning speed. In another factory they are assembling all the various intricate portions of the fuses, and in a somewhat more distant shop they are filling shells and hand-grenades with high explosives.

Most of this work is what is technically called unskilled or semi-skilled work; but as the demand for munitions continues to be urgent, and the supply of skilled mechanics more scarce, it is to be hoped that employers will begin to single out some of the clever women for positions of greater responsibility and that some of them will have a chance of further training.

Where so many thousands of women are working in one firm it would be a great advantage if provision could be made for some educated girls to go through the shops and gradually take control of the unskilled women workers.

In most large works the comforts and convenience of the women are admirably attended to within the factory, excellent hot dinners are served at a price that can only just pay the cost of materials, while hospital rooms and rest rooms are often provided.

In some of the smaller firms engaged on experimental work, some educated girls are already proving to be the most useful of skilled helpers. Some can be seen soldering metal parts together, others heating and bending light brass tubing, using the roarer and picking up the little tricks of tools of old hands. Some are drilling holes in brass castings, and shaping special parts for adjustment on their corresponding frames. Some few are even beginning to set the tools in the lathes, an operation requiring great skill and experience.

Difficulties of housing are keeping educated girls back from starting on a larger scale in this profession. Existing works have grown up amid surroundings one must bluntly describe as barbarous, and the new factories are rushed up so hurriedly to meet the urgency of the call for munitions that they have got ahead of the accommodation.

It is quite evident that if girls are keen to go into engineering at a time of stress like the present, they must take things as they are; but at the same time, when one considers the enormous number of women employed on munitions, nineteen thousand, to meet the extreme needs of the country, it cannot be thought unreasonable to press for some facilities for those who have had an expensive education as well as for the unskilled women.

A roomy hostel with civilised interior arrangements and meals decently served is the accommodation most comfortable and convenient tor girls.

Once the problem of lodging is solved, educated girls would not be long in setting to work to learn the routine of the shops, and then be ready to take advantage of such opportunities as may happen.

But there must be a reasonable chance of employment at the end of the training. Professional women cannot generally afford to give themselves a course of training unless it is for some definite object.

In engineering, as in medicine, few young men are entering the profession at present; but, so far, little provision has been made to supply their place with trained women.

The aeroplane factory would seem to possess great advantages for the training of women. A great deal of the work is very delicate and light. The lathes and drills are much smaller than those used for shell work, there is little repeat work, so that an intelligent girl would have a chance of rising to a better position if she showed mechanical skill.

The motor industry is perhaps the most accessible of the engineering professions open to women. Several enterprising firms hold special classes for women, where they are taught all the mechanism of the motor, learn to do repairs, and the care of the engine and body. Their classes are very well attended, and the workshops attached extremely popular, thus showing the readiness of girls to apply themselves to mechanics when they get the chance.

As drivers of many sorts of public cars, and of hospital ambulances, women are making a great success, and as drivers of private cars they are developing a new sort of service, as they are often able to combine the duties of driving the car with some other service useful in a household, such as secretary, reader, or gardener.

A good lead has been given to engineering for women by the plucky and patriotic action of the week-end lady munition workers at various large firms. At one firm some three hundred ladies go down and keep the lathes running on Saturday and Sunday. The output of some of the ladies has created great astonishment among the ordinary workers and the skilled foremen. Already some of them can set the tools in their lathes, and some of the most skilled are quietly qualifying themselves as mechanics, the idea being for the week-end women munition workers to bring their own skilled women mechanics with them; they would then be no longer open to the charge of keeping skilled men mechanics waiting on them on Sundays.

A pleasant feature is the good understanding that exists between the regular worker and her Sunday "relief"; the position of each is quite defined and consequently there is no friction.

Prospective Work.

If a favourable opportunity were to arise for establishing a factory for women, it would be a great step towards organising all our resources. A building such as one may find in the immense and expensive workhouses that used to be built, some few years ago, and are now happily not required by the poor, would be capable of housing the educated women workers needed in the factory. In the surrounding grounds, convenient and not too large workshops would be erected. The shifts would sit down to civilised meals in the ample dining-rooms of the building. The lavatories and bathrooms, thoughtfully provided for the paupers, would at last be appreciated and enter on a career of usefulness. The large hall, often an architectural feature of the workhouse, would be utilised for simple lectures on elementary mechanics, the uses of tools, on shops management, the assembling of tools and other subjects connected with the particular industry in hand, the object being to provide a quick emergency training.

The drawing offices too, would be conducted on commonsense lines; the girls working in them would have a chance of learning something of the uses of the drawings they are tracing.

It would not then be possible for a conscientious girl tracer to waste her time on diligently tracing in a knot in the wood of the board on which her work is fixed.

The work to be undertaken would preferably be of a small and not too heavy type, needing moderate sized lathes. The special work would be determined by what seemed to be most suitable for a women's factory; it need not necessarily be munitions of war.

It would be a happy idea if the women's firm were to specialise on making some of the innumerable articles that we have bought from Germany in increasing quantities till war broke out and stopped this supply.

Motor-cars, cycles, and parts	£1,479,000
Electrical machinery . . .	£721,000
Sewing-machines and parts .	£117,000
Cheap clocks and watches . .	£200,000

are some of the most common importations from Germany.

The cost of establishing a factory on these lines is outside the scope of a private firm or even of—at the present time—a company, on account of the difficulty of getting machinery, and it is clearly a case for the Government to give a lead and make some provision for future needs.

While young men are using their best energies in fighting the enemy, and elder men are using up their brains on inventing machines for his destruction, it should be made possible for women to begin a careful study and preparation of the business methods to be followed after the war is over.

I have ventured to make these suggestions because the Royal Society of Arts has always been kind and considerate to those who have some favourite scheme to propose; and the recommendations of this Society carry so much weight. I am not without hope of having some practical suggestions as to the best way of establishing a factory on these lines.

I wish to thank the ladies who have given me so much information as to their own professions. If any incorrect statements have occurred they have arisen entirely from my own inability to give the right value to some professional matters.

DISCUSSION.

Dr. Florence Stoney wished to thank Lady Parsons for her very interesting paper, which opened up great possibilities for women's work. She had been specially interested in what was said of the engineering profession as a sphere for women. She had very little knowledge of engineering work, but she understood that women were only employed in simple and lowly-paid work, and that all good posts were kept entirely in the hands of men, chiefly owing to Trade Union troubles. She hoped that matters would soon be improved in that respect. She was especially interested in medical work, in which women had great opportunities. The demand for women surgeons was becoming much more urgent, but the means of educating women students were very limited. There was only one general hospital in London open to women students, and that had less than two hundred beds. In the Women's Medical School there were more than two hundred students, and there was a great difficulty in women getting full clinical work, while the men's schools complained that they had not enough students to do the work. She knew of one hospital where one student had seventy cases at a time in his own charge, and though he could not properly do the work yet women were not allowed to come in and help. In all London there was not a single hospital amongst the old-established institutions which would afford a woman a chance of working on the staff. Even in hospitals devoted to sick women (except those which had been specially founded by women), although all the patients were women, a woman was not permitted to work on the staff. There were other professions which might be opened up to women. If women were incapable they would not be employed, but why should they be shut out from the profession of barristers,

solicitors, and accountants? No woman was allowed to drive a taxicab in London though she might drive her own private vehicle; women were driving cabs in other towns quite satisfactorily. She had no doubt many women would be grateful to Lady Parsons for her suggestion with regard to establishing a factory for women.

MISS F. M. GLADSTONE said Lady Parsons had not mentioned a very large number of openings for women in connection with voluntary work. There were now very large organisations growing up, such as the Women's Patrols, which had over two thousand members enrolled, and were doing useful work, so useful that probably the sphere of women police would be enlarged. There was an enormous number of women working in connection with the Y.M.C.A. in canteens and in promoting concerts. Women were so keen on such work, although it was very tiring, that there was a waiting list of between 500 and 600 names of ladies in London who wished to do the work. There was no shortage of women workers in that direction. She had heard that at Messrs. Vickers' engineering works one woman had so qualified herself that she had been given the position of a forewoman.

DR. E. STONE MILESTONE said that if women could do work, and do it well, they should be given equal pay to that which had been given to the men who had done the work hitherto.

DR. WILLIAM GARNETT said he had been interested a great deal in the efficient work that had been done by ladies in very many capacities, and wished to take the opportunity of expressing his thanks to Lady Parsons for the valuable information she had given in her paper. There were two capacities which had occurred to him in which ladies could render very valuable assistance. The first was in engineering departments, in gauging work as it came from the machines. Such work depended quite as much upon touch as upon sight, and that fact pointed to ladies as specially qualified for that class of work. Secondly, there was great scope for educated women in chemical laboratories, and he expected to find a very large amount of work for women in the preparation of drugs.

THE CHAIRMAN (Dr. Dugald Clerk) expressed his indebtedness to Lady Parsons for her summary of women's work. She had mentioned many lines on which advance could be made. Woman had behaved so magnificently during the war—as indeed she had always behaved—and had developed so many unexpected qualities, that her sphere of work was being enlarged. He quite agreed with Lady Parsons that there was a great field in engineering for women. At some works he was interested in in Manchester, on Tuesday—knowing that he was to be at the meeting that evening—he inquired how many women were engaged in shell-making, and found there were about fifty, and that accommodation was being provided for 150. A few of the women there were educated women, one being a vicar's daughter, who worked as skilfully as any man. He thought Lady Parsons had rather under-estimated the number of women employed in engineering. One factory in which he was interested employed, about fifteen years ago, 1,600 women, and he was informed by one of the directors that there were now some 6,000 women altogether. Gauging had long been a woman's speciality. At such a place as Kynochs, where they made a very great number of cartridges, women were very largely engaged. Every one of the cartridges had to be accurately gauged, so that it should not jam in the Maxim or fast-firing gun, and women had been employed on that work for twenty-five or thirty years, and great numbers were working in cartridge factories now. Their hands moved so fast on the gauges that one could hardly see them. They also were employed in turning cartridge-cases, and on some of the larger work hitherto performed by men. He noticed that in many works now women were working upon 3·3 high explosive shells, and in some cases on 4½-in. shells. Their work was extremely accurate, and their previous experience in gauging served them in good stead. It might be said of modern engineering that it was factory engineering. In the old days a great many separate machines were built up and individually fitted for screwing, chipping, filing, etc.; but nowadays, to make a factory pay, there had to be an immense amount of repetition work, and every engineering business was so managed as to divide all the working parts up, so that one man might be making piston rings for a year, another man cross-head pins, and so on. Women could now come in and learn one particular process, and do it as well as any man. With regard to the suggestion for starting a women's factory, to-day every engineer had to know something of commercial work and make things pay. Lady Parsons' husband was a commercial engineer as well as a distinguished technical engineer. The first necessity for an engineer was to keep out of the Bankruptcy Court, and that was not so easy as it looked. What between various restrictions, different people wanting goods very cheaply, and workmen wanting all the profit, it was rather a difficult task. He would be delighted to see ladies starting works and keeping out of the Bankruptcy Court. His experience showed him that his wife was a better business woman in many things than he was a business man, but still he would not like either Lady Parsons or Mrs. Dugald Clerk to be exposed to the difficulties of handling big works. Government shell factories were another matter; no doubt there was a very large field for women there, and the field would increase. He believed that far more work would be found for women after the war than there was before, and he was glad to find at the different works with which he was connected the prices paid to the women for piece-work were practically the same as those paid to the

men. There were some works where manufacturers were strongly tempted by the cheapness of women's labour, and were inclined to use it to displace men's labour, but it involved a political-economical difficulty. No' doubt, however, that difficulty would be overcome. The total income of Great Britain just before the war was something like £2,400,000,000, but only a little over £1,000,000,000 represented actual goods manufactured, the remainder being paid for professional and other services, selling, carrying, banking, etc. If women could be brought in he had no doubt the country could be made vastly more wealthy. The Trade Unionists were afraid of women because they believed they would reduce the standard of living, but if things were treated in an enlightened way, as he thought they would be after the war, the output in actual things necessary to abolish poverty would be greatly increased by the employment of more women, especially in the employment of men and women more in productive and less in luxury trades.

Lady Parsons, in replying to the discussion, said that voluntary work was a very large and interesting question; but she had rather dealt in the paper with work for professional women. With reference to equal wages for equal work, that was, of course, the whole foundation of the subject; it was necessary to insist on women being paid the same as men for the same work, but of course it would have to be the same work. A woman who worked for an hour could not expect the wages a man received for an hour's work unless she turned out the same amount. She did not intend to run any risk of going into the Bankruptcy Court herself, but she would like the Government to provide funds. The Government had put up large and expensive shell-works, which they would not want after the war, and it might be possible for women to take them over and make something which was absolutely necessary for the country. For instance, there were such modest things as tins. In Germany there was a large factory producing tins for foodstuffs, and such tins were very much wanted in this country.

On the motion of the Chairman, a hearty vote of thanks was accorded to Lady Parsons for her paper, and the meeting closed.

SUGAR IN 1915.

In their annual review of the sugar trade for 1915, Messrs. William Connal and Co. comment on the comparative ease and rapidity with which beetroot has been replaced by cane sugar during the year. In 1913 no less than 646,648 tons of beetroot were imported for the use of British refiners, and during the first seven months of 1914, previous to the outbreak of war, a further quantity of 217,514 tons had been received, whereas during 1915 the Royal Sugar Commission has succeeded in supplying all the wants of refiners from cane sugar alone.

It was no easy matter to time the arrival of cane cargoes in London, Liverpool, and Greenock so that refiners might never want raw material. On several occasions, it is true, stocks were well-nigh exhausted, but supplies never failed to arrive in time to keep refineries in full work.

Private enterprise could scarcely have accomplished this work, more especially during the later months, when tonnage has ruled at such an abnormally high figure, and has been almost impossible to obtain by ordinary traders. This difficulty could only be overcome by Government, which possessed the power to commandeer vessels as occasion required.

The replacing of beetroot by cane sugar involved the necessity of drawing on many cane-producing countries, each contributing its quota: from Mauritius, for example, which in 1913 only supplied the West with 20,000 tons of refining quality, 93,000 tons were obtained in 1915; but the principal sources of additional supply have been from the islands of Cuba and Java. In 1913 the entire crop of Java was absorbed by the East, but during the present year about 300,000 tons have been imported to the United Kingdom, while from Cuba about 350,000 tons have been obtained, or about 100,000 tons more than in 1914.

The wonderful fertility of Cuba is well known, and it is of interest to observe that, while in 1895—the year of the Cuban Insurrection—its crop of sugar had diminished to about 200,000 tons, it has since increased year by year by leaps and bounds, until last season it has amounted to 2,592,667 tons; and the crop now commencing is estimated by Mr. Himely at 3,175,000 tons, and by Mr. Guma at 3,183,628 tons, or about 600,000 tons more than that of last season. The flow of capital into that island under American control and the preferential treatment accorded by America to Cuban sugar have contributed to this development, and the enhanced price now being obtained for this large sugar crop should enable planters to acquire the most up-to-date machinery and encourage them further to extend cultivation.

The same may be said of Java, where in 1900 the crop was only 700,000 tons, but has now reached 1,300,000 tons, and where sugar in normal times can be produced at a minimum cost.

Our own West India Crown Colonies, in which the sugar industry, not having enjoyed the same fostering care bestowed upon Cuba, has long been on the verge of extinction, have now an opportunity of resuscitation. Estates, which three years ago only realised about 10*s*. f.o.b., for their crystallised sugars, can now obtain fully 5*s*. net per cwt. more. This should impart new life and vigour to planters who have so long and so courageously fought against adversity, caused largely, for many years, by unfair competition of Continental bounty-fed sugars.

PRICES OF CHEMICALS.

The annual report of Sir S. W. Royse & Co., Ltd., states that during the closing months of 1914 there was some reaction in values of a number of articles which had advanced too rapidly after the outbreak of war. Soon after the opening of the new year, however, a general advance in values commenced, which has, with some few exceptions, been continuous throughout the year. Sulphate of copper commenced the year at £22, and was £27 10*s*. in September, since when there has been a remarkably strong and steady advance to £45 per ton, mainly through short supply of vitriol; demand latterly has been active, but lower prices are quoted for delivery after February. Exports during the months January–November are 62,549 tons, value £1,537,950 against 74,751 tons, value £1,681,955 in the corresponding period of 1913. Green copperas was fairly steady until the middle of the year, since when there has been a heavy advance in value, production having considerably decreased. Lead salts have had a continuously strong market; the production of English white sugar of lead has increased, and price has advanced from £36 in January to £69 at present, mainly through increased cost of acetic acid. Nitrate of lead has at times been quite difficult to obtain, through shortage of nitric acid, and has advanced from £30 in January to the present value of £63. Litharge and red lead have advanced steadily, excepting a slight break in May, and are £14 per ton dearer, with makers heavily engaged for some time ahead. Grey acetate of lime has been very active, and, commencing the year at £9 10*s*., advanced to £18 in June, and since to present spot value of about £32, with very little offering. Brown acetate of lime has advanced similarly, and is scarce. Acetate of soda has advanced from £21 in January to £50 at present, and only little offering; the British production looked like being considerable, but some months ago was reduced for special reasons. Carbonate of potash advanced from £40 in January to £180 in July, but many consumers ceased to buy, and it has since declined to present value of £150, although offering only in small lots. Caustic potash rose from £48 in January to about £250 recently, but for some time quotations have been merely nominal, the market being practically cleared. Montreal potashes were £55 in January, and are now £150, and very scarce. Carbonate of ammonia was advanced from 3¾*d*. to 4¼*d*. in March, and to 4½*d*. in June, and has since been steady. Salammoniac rose from £49 to £52 in April, and to £55 in October. Muriate of ammonia has varied but little, the consumption for galvanising being less than usual. White powdered arsenic from £18 10*s*. fell about £2 per ton by the end of June, and then with a pronounced shortage rose rapidly to £30 in November, and is steady at £29 at present. Borax has always been selling steadily, and has advanced from £18 10*s*. in January to present value of £25. Yellow prussiate of potash fell 2*d*. per lb. to 1*s*. 1*d*. in January, and has advanced at first steadily and latterly rapidly to 3*s*. 7*d*., and scarcely anything offering for near delivery. Yellow prussiate of soda was 7¼*d*. in January, 6*d*. in February, and is now about 1*s*. 11*d*., and very firm. Tartaric acid was 1*s*. 6*d*. in January, and is now 2*s*. 6*d*., with the market very firm, this season's crop of raw material being reported small. Cream of tartar was £140 in January and £190 in June, and the subsequent fall of £10 in this article against the considerable rise in tartaric is puzzling. Bichromate of soda has advanced from 3½*d*. to 8½*d*., and bichromate of potash from 7*d*. to 1*s*. 4*d*., and makers are very heavily sold over next year. Oxalic acid has been continuously scarce, and has advanced from 8*d*. to 1*s*. 2½*d*.

GRAPHITE IN INDIA.

Graphite occurs in small quantities in various parts of India—in the so-called khondalite series of rocks in the Vizagapatam hill tracts, and adjoining Chhattisgarh Feudatory States, in a corresponding series of rocks in Coorg, in the Godavari district of the Madras Presidency, in the Ruby Mines district in Upper Burma, and in Travancore. It has also been discovered in Sikkim, where a graphite vein, averaging about 13 in. in thickness, has been found about half a mile to the north of the road from Tsuntang and Lachen. The quality of the mineral is said to be good, large bulk samples having given a return of 93 per cent. of graphite. Other veins of graphite are known to occur in the area, according to the Quinquennial Review of the Mineral Production of India, but have not been examined in detail.

The graphite deposits of Travancore occur under conditions similar to those of Ceylon, which is but a continuation of the charnockite series and associated rocks of South India. Small quantities of graphite have been extracted in Godavari and Vizagapatam, but practically the whole of the Indian ouput came from Travancore, where the average used to be about 13,000 tons annually. Owing to the difficulty of working at increased depths, however, the mines were no longer found to pay, and were shut down in 1912.

ENGINEERING NOTES.

A High Masonry Arch Viaduct in France.—The new viaduct over the Tet River is a modern structure of granite masonry designed on the two-level principle with remarkable architectural effects to conform to the rock profile and the natural beauty of the site. Its masonry arches are supported on high piers, one of which is itself carried on the crown of a pointed arch below. A description of this work, which was designed by Professor Sejourne, is given by

A. Dumas in *Le Génie Civil* for November 6th, 1915. The plans show the extraordinary character of this modern construction and its resemblance to the old Roman aqueducts. It is notable in two features—the designer has spanned the lower narrow ravine by a 98 ft. 6 in. pointed arch, upon the keystone of which a high intermediate pier of the main arch viaduct is supported, and he has decreased the cost of the main arches by reducing their width to the minimum compatible with the lateral stability, and the general magnitude of the structure, by carrying the footways on an overhanging reinforced-concrete floor slab supported on cantilever beams. The height of base of rail above the river is nearly 225 ft. High massive towers serve to divide the main structure from the arch approach at each end. All four of the main arches are of the same clear span, about 56 ft., with full-centered circular intrados. Spandrel arches are used in the solid rubble masonry. The viaduct is on a grade of 6 per cent., and the approaches consist of circular arch spans about 29 ft. clear between piers, two on one side and ten on the other. The four main arches are 8·2 ft. wide at the top, which is sufficient to carry the narrow-gauge track and provide for the footways on each side by cantilever brackets. This total width of arches and piers increases at a constant batter to 13·65 ft. at the bottom of the high pier over the lower arch. This lower arch is 17·3 ft. wide at the crown and 22·15 ft. wide at the springing line, with a thickness of 8.2 ft. at the crown, and 11·5 ft. at the springing line. The maximum stress at the time of striking centres for the lower pointed arch was computed to be about 206 lb. per square inch. This decreases under service conditions to 175 lb. per square inch at the springing line, and 142 lb. at the crown. These figures increase to nearly 200 lb. and 242 lb. respectively when the temperature rises 10°, and decrease slightly when the temperature decreases. In the four main arches the maximum pressure is nearly 370 lb. per square inch at the springing, and 440 lb. at the crown. These high figures are admissible because of the excellent granite used, and the exceptional quality of the construction work. Ballast for the railway track is carried by overhanging reinforced-concrete slabs. An unusual feature is the use of spiral reinforcement in the lower sections of the cantilever beams. The designer of the structure, Professor Sejourne of l'École des Ponts et Chaussées, always lays great stress upon the architectural appearance of his bridges. The temperature stresses were computed by Professor Pegeaud, also connected with the same institution in Paris.

Railway Progress in South Africa in 1915.—The middle of the past year saw the South African railways joined up with the German system in South-West Africa, it being possible to run trains from Johannesburg to Swakopmund and Luderitzbucht, and *vice versâ*. The link between the two systems was built in record time—three miles per day. Although the Railway Department had to undertake an immense amount of additional work during the rebellion and the German South-West campaign, the year saw a further extension of the open mileage, and an improvement in many of the details of the service.

Russian Waterways.—The *Times* says, among the projects which, apart from the building of railways already decided upon, seem to have some chance of being realised within the near future for the benefit of Northern Russia, is that for the construction of a waterway between the White Sea and Lake Onega. This waterway, which would proceed either from the town of Onega or the small town of Suma on the south coast of Onega Bay, in the White Sea, and go straight in a south-west or southern direction to the town of Povjenets, on Lake Onega, in the Government of Olonetz, would give communication between the White Sea and the Russian canal system, as Lake Onega is in direct connection, on the one side, through the River Svir and Lake Ladoga, with Petrograd, and on the other, through the Marie Canal and the Alexander of Würtemberg Canal, with the Volga River system. The Imperial Russian Agricultural Society is understood to be working energetically for the realisation of this scheme, and has proposed to the Government that the construction of the canal should be left to a private company, subject to the guarantee that all State and industrial considerations should be observed. Among the benefits likely to be derived from such a waterway are the advantages and facilities it will offer to the transport of goods between England and America on the one hand, and Russia on the other. At the same time it will greatly assist both the exploitation for the advancement of industry of the waterfalls situated in those districts, and the solution of the Russian fuel problem. In connection with the latter, the Russian peat fuel committee draws attention to the vast peat deposits in the districts through which the canal would pass, and which, it is held, can supply both the northern and interior parts of Russia, as well as the Kola-Petrozavodsk railway with cheap fuel. The White Sea for two and a half to three months of the year already has connection with the other Russian water systems through the Dvina-Suchona Rivers; but owing to shortage of water in the latter this river traffic can rarely be continued beyond Kotlas after the middle of July. The traffic on the River Onega generally stops in the beginning or middle of November, and remains closed until the beginning of May, so that if similar conditions were to apply to the

new canal it could be used only for about seven months in the year.

Atlantic to Pacific: another Link in the Chain.—The first through train over the line of the Canadian Northern Pacific Railway left Montreal, Quebec, on October 12th at 5 p.m., and arrived in Vancouver, British Columbia, early in the morning of the 19th. The trip was made as an inspection of the line preliminary to the inauguration of regular service on November 1st, which commenced with a through passenger train service of three times a week. On the train were twenty members of the Canadian Senate, fifty members of the House of Commons, and thirty newspaper men. The last spike in the new transcontinental line was driven at Basque, British Columbia, 182 miles east of Port Mann, on January 23rd, 1915. The system opened its first line in Central Manitoba in 1896, and now has in operation about 10,000 miles of single track.

Electric Heating.—In a paper read before the Institution of Electrical Engineers, Mr. George Wilkinson proposed to control electric heaters thermostatically, so that rooms might be kept automatically at an even temperature. The author suggested that heaters should have a rating of not less than 1½ watts per cubic foot of room space, and of at least 2 watts in the case of rooms which have an abnormal window area or an exposed situation, or are subject to draughts and traffic. But if 1½ watts is sufficient for the coldest day, it is obviously excessive and therefore wasteful for every other day, and the crude regulation obtained by providing only one or two switches does not furnish the required control. It was also his opinion that there is a promising field for electric heating in cases where coal fires or radiators are already in use. Owing to the vagaries of combustion both these methods of heating are subject to wide variations of temperature, and the cool periods could be readily removed with little expense for current if thermostatically controlled electric heaters were fitted as an auxiliary.

Self-Starting Oil-Engine.—A horizontal four-cycle oil-engine designed for heavy duty has been invented. By using a compression of not more than 300 lb. an engine of comparatively light weight has been built. The engine bed is braced by steel tie-rods; these tie-rods serve as rails for a small device which acts as a travelling crane, thus permitting one man to replace or remove heavy parts of the engine. The fuel is atomised by means of a hydraulically operated sprayer. When started the gases are ignited by a hollow ring enclosed in the water-cooled cylinder head, which is heated by a torch burning some of the same fuel used to operate the engine. As soon as the engine has made a few revolutions the heat of the piston plus the heat of the compressed air in the cylinder is sufficient to ignite the oil. The governor is fixed directly to the cam shaft, and is so designed that in case the engine should be reversed it automatically cuts off the supply of fuel. One of the features of this engine is its principle of self-starting.

School of Practical Engineering, Crystal Palace, Sydenham.—It is very gratifying to know that, in spite of the terrible war now raging, and which has caused financial difficulties to many institutions, the above school, which was established in 1872, is to be carried on as usual (under the Principal, Mr. J. W. Wilson, M.Inst.C.E., M.I.M.E.). The school provides students of mechanical, civil, and other branches of engineering with thorough practical and theoretical instruction in the rudiments of the profession, and in the manipulation of materials, special facilities being afforded to colonial students. The success attained is borne out by the subsequent careers of many of the students; as examples may be mentioned the chief engineer of the Port of London Authority, chief engineer of the South African Railways, chief engineer for the Federated Malay States Railways, acting chief engineer of the Great Indian Peninsular Railway, chief bridge engineer of the Canadian Pacific Railway, and the city engineer, Birmingham.

NOTES ON BOOKS.

THE RARE EARTH INDUSTRY. By Sydney J. Johnstone; with chapter on the Industry of Radioactive Substances by Alexander S. Russell. London: Crosby Lockwood & Son, 1915. 7*s.* 6*d.* net.

The industrial importance of the rare earths is of the last few years, and the recent culmination of utility upon utility is almost like a romance when considered in relation to those elements which fifty years ago were often mentioned in the text-books as if they were useless superfluities of Nature; superfluities annoying to the chemist by so greatly complicating his scheme or system of inorganic analysis.

Even in the early days of modern chemistry we find Faraday and Stodart, as also other investigators, studying the effect of various small additions to steel, as, for example, chromium, rhodium, osmium, titanium or tungsten, and of all these additions that which made most for consideration and industrial trial was tungsten; yet if we turn to a typical standard text-book of some forty years ago we read in respect to tungsten steel: ". . . Experience does not seem to justify the expectations of its utility . . . A similar remark is also applicable to titanium steel"—quoted from Percy's

"Metallurgy," and to be found on page 633 of Vol. II. of Miller's "Chemistry," 1878 edition. Thus was cast aside that use of tungsten which is so fruitfully serviceable at the present time.

Of all the rare "earths" tungsten is, perhaps, the most abundant, and we need not dwell on our author's account of the recent applications of tungsten in relation to the steel manufacture, as, for example, in making of high-speed tool steels and rustless cutlery; but special mention may be made of the details given as regards the production of malleable or ductile tungsten and the means adopted for drawing it into the extremely fine wire which is required for the modern electric glow-lamp; the fulness but conciseness of the account, the numerous diagrams illustrating the stages, the numbered and headed paragraphs defining the steps in the process, and the references to patents or original papers, all conducing to make this description a notable one from the standpoint of technical book-making. An example of that culmination of utility upon utility to which we refer above is afforded by the fact that tungsten drawn wire, if pure, is subject to the serious defect of becoming crystalline and brittle after long use, but this defect can be more or less perfectly eliminated by alloying the tungsten with small quantities of still rarer "earths."

By our use of the word "earth" in the above sense, we wish very fully to endorse the title of Dr. Johnstone's book, and also the sentiment in the introduction, whereby metals like tantalum and tungsten are included among the earths. This is going back to the older use of the term "earth," as, for example, some three hundred years ago when earth, mineral, metal, and fossil all had a similar meaning, or, indeed, we may go back to the four primaries of the school of Aristotle as suggesting the respectability of the broad term, as far as age is concerned.

The narrow conception of "earths" became current soon after Black's "Study of Magnesia" (1755), and was made inconsistent when Davy (1807) proved such bodies to be merely the ores or oxides of metals. Hence our author's broad term, or reversion to the older usage, appears desirable and reasonable—at any rate, convenient.

The work is definitely practical, and as it is assumed that the reader has a good general knowledge of chemistry there is no waste of space in explaining elementary matters, but chemical details that are specially pertinent to the subject-matter are included. The scope of the work covers the practical technics relating to thorium and cerium (including full details as to mantle manufacture), titanium, zerconium, tantalum and niobium, tungsten, uranium, vanadium, also radium and its congeners; special care having been taken in relation to the bibliographical aspect, so that the reader may find himself in a position to refer to original sources, whether books, contributed papers, or patent specifications.

The appearance of the work is opportune in relation to present needs of British trade expansion; and in expressing a hope that the sale may be large we indirectly imply our high opinion as to the sterling qualities of the work, as also our appreciation of the laborious care on the part of those concerned—Dr. Geoffrey Martin, who edits Messrs. Crosby Lockwood & Sons' new series of Manuals of Chemical Technology; Dr. S. J. Johnstone, who is the author in the ordinary sense of the term; and Dr. A. S. Russell, who contributes the section on the industry of radioactive substances.

Standard Cloths. By Roberts Beaumont, M.Sc., M.I.Mech.E. London: Scott, Greenwood & Son. 12*s*. 6*d*. net.

In standardising cloths the two principal points to be considered are the nature of the fibrous materials used, and the various processes and methods of operation through which the cloths pass. In order to elucidate the technical scope and diversity of the subject, the author has studied collections of trade, general, and original specimens, and verified the data by experimental research; and the volume consists largely of analyses and illustrations of typical fabrics, with expositions of the principles and schemes of manufacture which they represent.

The first chapter deals with the microscopic features of woven fabrics, of which an excellent idea is given by the various photomicrographs reproduced. From this we pass to the application and meaning of the word "quality." Chapter III. gives a synopsis of cloths, and this is followed by chapters dealing with standard grades of manufacture, weaves types, fabrics light in weight and structure, medium-weight woollens, medium-weight worsteds, overcoating cloths, army and navy cloths, and finally felt manufacture.

The advantages of a standardisation of fabrics in facilitating commercial dealing are obvious, and Professor Beaumont's work towards securing such standardisation will be welcomed by workers in the textile world. The book is well got up and the numerous illustrations are excellent.

Paint and Colour Mixing. Fifth Edition. By Arthur Seymour Jennings. London: E. & F. N. Spon, Ltd. 6*s*.

The first edition of this practical handbook appeared in 1902. Its value was at once recognised by painters, decorators, paint manufacturers, and all who have to mix colours. Fresh issues followed one another, and now the book has reached its fifth edition, which completes a total issue of ten thousand copies.

Several new chapters have now been added by the author, of which the principal deal with

"Mixing and Matching Colours," "Straining Colours," "Putty Hard Stopping, Knife and Brush Filling," and perhaps the most valuable of all, "Two Hundred Standardised Colours." In this section a list is given of the colour names, with their constituent pigments.

Not the least valuable feature of the book are the plates, which have been produced with great care. They comprise together nearly three hundred specimens in actual paint of differently-named tones, and should prove very useful in establishing on a more sure foundation the nomenclature of colours.

GENERAL NOTES.

War News for West Indian Coolies.—With reference to two General Notes which have appeared in the *Journal* describing the publication in India of war news in native languages, Mr. Edward A. V. Abraham, of Georgetown, British Guiana, sends us copies of news-sheets printed in Hindi and Urdu, and circulated among the coolie population of the colony. The sheets are plentifully illustrated with war photographs, and should be useful in keeping their readers informed of the progress of hostilities.

Mine Rescue Signalling Device.—Writing in the *Coal Age*, Mr. O. Cartlidge, Manager of Mine Rescue Stations, Illinois, has described a cheap and convenient signalling outfit for men engaged in rescue work in mines. Three No. 6 Columbia dry cells are placed in the centre of a drum on which is wound 1,000 ft. of round insulated No. 16 three-wire cable. Signalling is effected by pressing buttons operating "buzzers" of the ordinary type. That at the free end of the cable is fastened to the rescuer's belt, and about 5 ft. along the wire from this is attached a stout cord, at the other end of which is a hand-grip, so that the man can pull the cable along without straining the connections; similar hand-holds are placed at intervals along the wire for other members of the gang. This apparatus (which does not weigh more than 100 lb.) has an advantage over a telephone in that the signaller does not have to attempt articulation in a suffocating atmosphere.

Ceylon Plumbago.—The loss of the German and Belgian markets was a severe blow to the plumbago mining industry in Ceylon, and steps were taken by the Imperial Institute to induce users of plumbago in the United Kingdom to purchase their supplies entirely from Ceylon instead of partly from Ceylon and partly from foreign countries, as had been their previous custom. Considerable progress has now been made in this direction, according to *Engineering*, for the percentage of Ceylon plumbago exported to the United Kingdom during the first ten months of 1915 is considerably greater than in 1913. Further, the total exports to this country from January to October are more than double those of the corresponding months in 1914, while Russia also is a large new purchaser. The principal use of plumbago is in the manufacture of steel-works crucibles, which are required to resist the effects of great variations of temperature.

The Fish Supply of Calcutta.—Though Calcutta is on a river and only ninety miles from the sea, its fish supply is poor in quantity and variety. Of the want of variety everyone can speak. The only fish with flavour which the European is usually permitted to eat is *hilsa*, which has been compared with mackerel, and is as oily as a herring. Yet there is good fish in the sea, as the explorations of the "Golden Crown" sufficiently showed. It will be remembered that the results of these investigations were described in a paper read before the Society in 1911 by Dr. J. Travis Jenkins, who pleaded for the establishment of a Fishery Board in India, and urged that it was the duty of the Government to encourage, in every way in its power, the development of this natural source of food supply. Mr. Southwell, the Deputy Director of Fisheries, has now demonstrated that the supply is far below the requirements of the population. The amount which reaches Calcutta in a year is 3,625 tons, or less than ten tons a day for a city of a million inhabitants, of whom the vast majority eat only fish when they take any animal food.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

February 9.—Professor J. A. Fleming, M.A., D.Sc., F.R.S., "The Organisation of Scientific Research." Dugald Clerk, D.Sc., F.R.S., Chairman of the Council, will preside.

February 16.—S. Charles Phillips, M.S.C.I., "Paper Supplies as affected by the War." Lord Burnham will preside.

February 23.—Miss H. B. Hanson, M.D., B.S., D.P.H., "Serbia as seen by a Red Cross Worker."

March 1.—Charles Delchevalerie, "Belgian Literature."

March 8.—Charles R. Darling, A.R.C.Sc.I., F.I.C., "Optical Appliances in Warfare."

MARCH 15.—EDWARD PERCY STEBBING, F.L.S., F.R.G.S., Head of the Department of Forestry, University of Edinburgh, "Forestry and the War."

INDIAN SECTION.

FEBRUARY 17.—C. A. KINCAID, C.V.O., Indian Civil Service (author of "Deccan Nursery Tales," "The Indian Heroes," "The Tale of a Tulsi Plant," etc.), "The Saints of Pandharpur: the Dawn of the Maratha Power." LIEUT.-COLONEL SIR DAVID W. K. BARR, K.C.S.I., will preside.

MARCH 16.—PROFESSOR WYNDHAM R. DUNSTAN, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India."

APRIL 27.—JAMES MACKENNA, M.A., I.C.S. (Deputy Commissioner, Myaungmya, Burma, and designated Agricultural Adviser to the Government of India), "Scientific Agriculture in India."

MAY 18.—SARDAR DALJIT SINGH, C.S.I., "The Sikhs."

COLONIAL SECTION.

FEBRUARY 28 (Monday, at 4.30 p.m.).—PERCY HURD, "Next Steps in Empire Partnership."

Dates to be hereafter announced :—

R. W. SETON-WATSON, D.Litt., "The Balkan Problem."

REV. P. H. DITCHFIELD, "The England of Shakespeare."

W. A. CRAIGIE, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

VICTOR HORTA, Directeur de l'Académie Royale des Beaux-Arts de la Ville de Bruxelles, "Belgian Architecture."

PROFESSOR T. G. MASARYK, "The Slavonic Peoples."

G. P. BAKER, "Hindu Hand-painted Calicoes of the Seventeenth and Eighteenth Centuries, and their Influence on the Tinctorial Arts of Europe."

ARTHUR S. JENNINGS, "Painting by Dipping, Spraying, and other Mechanical Means."

SIR DANIEL MORRIS, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m. :—

March 21, April 11, May 2.

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m. :—

J. ERSKINE-MURRAY, D.Sc., F.R.S.E., M.I.E.E., "Vibrations, Waves, and Resonance." Four Lectures.

May 1, 8, 15, 22.

FOTHERGILL LECTURES.

Monday afternoons, at 4.30 p.m. :—

REV. DR. HERBERT WEST, D.D., A.R.I.B.A. (author of "Gothic Architecture in England and France"), "National and Historic Buildings in the War Zone: their Beauty and their Ruin." Three Lectures.

Syllabus.

LECTURE I.—FEBRUARY 7.—*Belgian Architecture and History.* Belgium a land of cities—What makes a city (Gen. xi. 4)—Tower—Church—Communal Hall—Belgian civil architecture, commercial—Cloth Halls before Town Halls—Churches borrowed, but splendid furniture given by Trade Guilds. Ypres typical—Tournai. Rhenish. Source of Noyon—Soissons. St. Remi—French efforts to annex Flanders—The Matins of Bruges—Battle of the Spurs. Courtrai—Rivalry of Ghent and Bruges—Edward III. and J. van Artevelde—Sluys—Coucy. Pierrefonds—Mediæval sieges—Philip van Artevelde, Roosebek. Suzerainty of Burgundy—Charles the Rash and Louis XI. Dinant—Sack of Liége. Mary of Burgundy. Arras—Lierre. Charles V. and Philip II. Egmont and Horn—Louvain—Malines—Antwerp—Louis XIV. and William III. Namur. Bombardment of Brussels.

LECTURE II.—FEBRUARY 14.—*Gothic Architecture, French and English.* The French Cathedral, a Great Hall, the centre of the city's life. The English Cathedral a Monastic Missionary settlement, independent of the city. The problem of Mediæval Architecture, to reproduce Roman vaulting—Solved by permanent stone centrings (diagonal ribs) under the intersections of a groined vault (Vezelay, Durham, St. Denis, Sens). Buttresses necessary (Chartres, Amiens, Beauvais). The walls become screens of glass. Inside—Columns replaced by vaulting ribs running down to the ground (Notre Dame—N. D. de l'Épine, Abbeville). Contrast of French and English plans (Notre Dame and Salisbury). In the English Cathedral, horizontal, not vertical perspective sought. Beauty of clustered columns. Purbeck causes deep mouldings. Multiplication of vaulting ribs. Lierne and fan vaulting—Flamboyant and perpendicular—English and French façades—The French Cathedral is the expression of the National ideal; the English, of the National history.

LECTURE III.—FEBRUARY 21.—*French Mediæval Sculpture.* Christian art that of a new-born society rising amidst a dying civilisation—Provençal sculpture, Arles, etc., decadent—Burgundian, full of life and imagination; but Classical influence traceable all through (Vezelay, Autun,

Auxerre)—XIIth Century (Avallon, Bourges, N. and S. doors, Chartres, W. front). Elongation of statues, architectural not ignorant—Individual types, elaborate detail. The sculpture scheme of a XIIIth Century cathedral (Laon, Notre Dame, Amiens, Reims). The Judgment door (Autun, Notre Dame, Amiens, Rampillon, Reims, St. Maclou)—The Virgin's door—Local Saints and legends (St. John Baptist, Rouen; St. Stephen, St. Théophile, Paris; St. Thomas, Semur; St. Nicaise, Reims)—The Arts, Virtues and Vices—The Months and Daily Life (Paris, Amiens, Rouen)—Statuary (St. Stephen, Sens—The Virgin, Paris—Chartres, N. and S. porches)—Reims, W. portals—Figures of Christ (Chartres, Amiens, Reims, Troyes, Solesmes).

The lectures will be illustrated by lantern-slides.

EDWARD A. REEVES, F.R.A.S., Map Curator, Royal Geographical Society, "Surveying." Three Lectures.

March 27, April 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 7...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cantor Lecture.) Rev. G. H. West, "National and Historical Buildings in the War Zone: their Beauty and their Ruin." (Lecture I.)

Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Rev. C. Lias, "The Unity of Isaiah."

Electrical Engineers, Institution of (Local Section), at the South Wales Institute of Engineers, Park-place, Cardiff, 5.30 p.m. Mr. O. L. Record, "The Testing of Underground Cables with Continuous Current."

Engineers, Society of, Caxton Hall, Westminster, S.W., 5.30 p.m. Presidential Address by Mr. P. Griffiths.

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m.

Surveyors' Institution, 12, Great George-street, S.W., 5 p.m. Mr. C. F. Slater, "Dilapidations—Some Notes and Suggestions."

Geographical Society, Burlington-gardens, W., 8.30 p.m. Mr. H. C. Woods, "Communications in the Balkans."

Economics and Political Science, London School of, Clare-market, W.C., 5 p.m. Hon. W. P. Reeves, "The Balkan States." (Lecture I.)

TUESDAY, FEBRUARY 8...Electrical Engineers, Institution of (Local Section), 17, Albert-square, Manchester, 7.30 p.m. Mr. O. L. Record, "The Testing of Underground Cables with Continuous Current." (Scottish Section.) Princes-street Station Hotel, Edinburgh, 8 p.m. Mr. H. H. Harrison, "The Principles of Modern Printing Telegraphy."

Asiatic Society, 22, Albemarle-street, W., 4 p.m. Professor D. S. Margoliouth, "The Islamic Pulpit."

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. S. Sherrington, "Nerve Tone and Posture." (Lecture IV.)

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Mr. W. T. Lucy, "Notes on the Working of a Rack Railway."

Photographic Society, 35, Russell-square, W.C., 7 p.m. Annual General Meeting.

Zoological Society, Regent's Park, N.W., 5.30 p.m. 1. Professor E. B. Poulton, "On a Collection of Moths made in Somaliland by Mr. W. Feather; with Descriptions of New Species by Sir G. F. Hampson and others." 2. Professor H. G. Plimmer, "Report on the Deaths which occurred in the Zoological Gardens during 1915, together with a list of the Blood-parasites found during the year."

Colonial Institute, Hotel Cecil, Strand, W.C., 8.30 p.m. Mr. J. L. Garvin, "The British Empire and the Near East."

WEDNESDAY, FEBRUARY 9...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Professor J. A. Fleming, "The Organisation of Scientific Research."

Biblical Archæology, Society of, 37, Great Russell-street, W.C., 4.30 p.m. Mr. E. J. Pilcher, "The Battle of Michmas."

Automobile Engineers, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. W. D. Williamson, "Petrol Engines for Commercial Vehicles."

University of London, King's College, Strand, W.C., 5.15 p.m. Mr. S. Low, "The War and the Problems of Empire." (Lecture II.)

Electrical Engineers, Institution of (Yorkshire Section), Philosophical Hall, Leeds, 7 p.m. Mr. O. L. Record, "The Testing of Underground Cables with Continuous Current."

THURSDAY, FEBRUARY 10...Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Sir Frank Dyson, "Measurement of the Brightness of Stars—Visual and Photographic Magnitudes." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8 p.m. Professor W. C. Anderson, "Salonica and the Country Round."

Optical Society, at the Chemical Society, Burlington House, W., 8 p.m. Dr. W. J. Ettles, "Optical or Visual Signalling."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Mr. O. L. Record, "The Testing of Underground Cables with Continuous Current."

FRIDAY, FEBRUARY 11...Royal Institution, Albemarle-street, W., 5.30 p.m. Professor W. M. Flinders Petrie, "Egyptian Jewellery."

University of London, Bedford College, York Gate, Regent's Park, N.W., 5 p.m. Professor W. R. Sorley, "The International Crisis: the Theory of the State. Lecture II.—The State and Morality."

Astronomical Society, Burlington House, W., 5 p.m.

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m. Annual General Meeting.

SATURDAY, FEBRUARY 12...Royal Institution, Albemarle-street, W., 3 p.m. Sir Sidney Lee, "The Shakespeare Tercentenary. Lecture II.—Shakespeare as a National Hero."

Correction.—In the report of Sir Frederic M. Hodgson's remarks on Mr. J. Arthur Hutton's paper, "The Effects of the War on Cotton-Growing in the British Empire," in the sixth and fifth lines from the bottom of col. 1, p. 222, for the words, "British Guiana" read "the Gold Coast."

Journal of the Royal Society of Arts.

No. 3,299. VOL. LXIV.

FRIDAY, FEBRUARY 11, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 14th, 4.30 p.m. (Fothergill Lecture.) REV. DR. HERBERT WEST, D.D., A.R.I.B.A. (author of "Gothic Architecture in England and France"), "National and Historic Buildings in the War Zone: their Beauty and their Ruin." (Lecture II.)

WEDNESDAY, FEBRUARY 16th, 4.30 p.m. (Ordinary Meeting.) S. CHARLES PHILLIPS, M.S.C.I., "Paper Supplies as affected by the War." LORD BURNHAM will preside.

THURSDAY, FEBRUARY 17th, 4.30 p.m. (Indian Section.) C. A. KINCAID, C.V.O., Indian Civil Service (author of "Deccan Nursery Tales," "The Indian Heroes," "The Tale of a Tulsi Plant," etc.), "The Saints of Pandharpur: the Dawn of the Maratha Power." LIEUT.-COLONEL SIR DAVID W. K. BARR, K.C.S.I., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

FOTHERGILL LECTURE.

On Monday afternoon, February 7th, the REV. DR. HERBERT WEST, D.D., A.R.I.B.A., delivered the first lecture of his course on "National and Historic Buildings in the War Zone: their Beauty and their Ruin."

The lectures will be published in the *Journal* during the summer recess.

PROCEEDINGS OF THE SOCIETY.

NINTH ORDINARY MEETING.

Wednesday, February 9th, 1916; DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Anderson, Frank Bartow, The Bank of California, San Francisco, California, U.S.A.

Dhari, Alakh, Oudh Commercial Bank, Limited, Fyzabad, India.

Farman, John, "Kirkholme," 16, St. James'-avenue, Beckenham, Kent.

Lall, P. C., Purnea City, Behar, India.

The following candidates were balloted for and duly elected Fellows of the Society:—

Bird, Captain Clarence A., R.E., 42, Fordhook-avenue, Ealing Common, W.

Crowther, Charles, 63, Yamamoto-dori 4 Chome, Kobe, Japan.

The paper read was—

THE ORGANISATION OF SCIENTIFIC RESEARCH.

By J. A. FLEMING, D.Sc., F.R.S.,
University Professor of Electrical Engineering in University College, University of London.

In the last forty years there has been a slowly progressive enlargement in the provision made within the British Empire for conducting and encouraging scientific research, though by no means proportional to the necessity for it.

Nevertheless, we have had forced on our attention by facts which admit of no denial that if we are to retain a leading position in the industrial world we must devote far more attention to it, and increase the degree to which we bring scientific knowledge and methods to bear upon all the problems of commerce and manufacture.

Amongst the indirect results of this appalling war we may hope that there will be some increased appreciation in the minds of the politicians who govern us of the enormous influence of scientific research and discovery, even in its most abstruse forms, on the prosperity and safety of the Empire. We have had brought home to us that this war is a war quite as

much of chemists and engineers as of soldiers and sailors. Hence, from the point of view of national security alone, we must take steps to foster scientific investigation. We shall probably never succeed in convincing the unthoughtful multitude of the manner in which the highest scientific researches affect human life in innumerable ways, but it will be sufficient if that fact is brought home to the consciousness of those who have political position and power, and if we can impress upon them that theirs will be the responsibility if they neglect to encourage it.

It cannot be too emphatically stated, however, that there are no short cuts to great national achievements in scientific work. We have first to produce the right conditions and environment for assisting genuine scientific work of an advanced character, and not merely to open up new fields of activity which can be exploited by second-rate ability. We require to produce the men and the ideas even more than the material appliances and facilities.

The public is, moreover, too prone to judge of the success or value of scientific work by the degree to which it can be immediately applied in what are called useful purposes.

They require to be instructed that we cannot produce merely the knowledge which is instantly utilisable in common life. Just as we can only convert a part of any quantity of heat into mechanical work when working as usual at temperatures above the absolute zero, so we cannot convert the whole of any scientific knowledge into useful applications; we have to create that knowledge disinterestedly, and then some applications will follow.

This practical invention is much affected by other factors, such as our patent laws, fiscal policy and wise or unwise commercial legislation. These will require thoughtful revision in view of coming competition.

The fundamental question before us, then, is the consideration of the conditions under which we can best increase our knowledge of natural phenomena, laws and materials, and place that knowledge in the form in which applications will most probably arise.

It obviously divides itself into the three sections, (1) Methods, (2) Means and (3) Men.

I. The Methods of Scientific Research.

The great bulk of all our scientific discovery and research in the past has been due to individual labour and initiative; much of it a labour of love, unrecognised at the time. Men of great genius have opened up new lines of thought or pursued private researches often with very inadequate appliances. In fact, the greater part of past British scientific research may be said to have been amateur work, not in the sense that it was lacking in the highest qualities, but only in the sense that it was pursued for the sheer pleasure and interest of it by private individuals. It was done mostly at odd times, and nearly always at the worker's own expense. The whole early history of electricity and of astronomy is a history of amateur work of this kind. From its very nature, therefore, it was disconnected. Each worker took up that particular bit of research which attracted his attention or offered novelty, and laboured at it in privacy.

In some cases useful scientific partnerships have been established, in which each worker supplied what the other lacked. Later on came the stage of committees, such as those of the British Association or Engineering Societies, in which a number of investigators united in some piece of research. Even then there has been a more or less disjointed action and want of co-operation between different associations.

This individual self-directed work is in keeping with our national character, but has its drawbacks as well as its strength.

It enables pioneers to open up new fields of discovery, but it retards our power of exhausting those fields of the full wealth of knowledge they contain.

In our research work this individuality has been cultivated to a point at which the Proceedings of our learned societies have become a heterogeneous mass of recorded researches which bear little relation to each other, though they may follow certain general groupings of subjects. Moreover, these researches are of very unequal value. In the case of some they are marked by great originality and genius, in the case of others they are of the nature of gleanings in a field already harvested by vigorous reapers.

The point then seems to have been reached at which the first attempt to organise research should be to create something more resembling an army out of the multitude of independent scientific workers. An army is not a collection of armed individuals, each pursuing his own aims and ideas. It is a complex organism in which each man has place and duty. No great enterprise can be carried out unless there is some degree of surrender of initiative and acceptance of directions from a higher command.

To carry out this principle in scientific work it appears to me that we require to a fuller

extent than we have it at present the system of scientific work done to order. This means that young investigators, and even older ones, shall be content to take up pieces of prescribed work, quantitative or qualitative, and carry it out individually or conjointly in connection with certain large plans of operation. This is something quite different from a research student conducting a piece of work, say, at the suggestion of a professor, and working it out on his own lines. There is just as much difference as between building a very small cottage to your own design and taking part in building a very large building to plans drawn up by a group of expert architects.

This conjoint or co-operative work would have several advantages. It would save much reduplication, and it would train beginners in the best methods of research. It would effect a saving of time and enable us much more quickly to reach a given point. There is much plain and straightforward research which can be carried out when its general lines are indicated to those not possessing very great originality, but yet having perseverance, accuracy, and skill.

If, however, such work is to be undertaken by those who may perhaps be called the privates and non-commissioned officers of the scientific army, then it presupposes a directing power which shall supply what I have elsewhere called the strategy of scientific research. This must, of course, come from the more experienced and able workers, and it is to them that we must look for ideas. If some men are to surrender initiative in their work, then others must give time and thought to planning the outlines of the scientific campaigns.

We need not only the regimental officers but the General Staff if there is to be effective achievement. My contention is that this specification of the main lines of suggested research is a matter which should largely occupy our learned societies, and, in particular, the Royal Society, from its broad and general character and unique position.

These societies have become, with few exceptions, chiefly paper-reading and paper-publishing societies. They accept, if suitable, accounts of self-suggested work from their members and others, and their Proceedings are, for the most part, a record of an immense number of disconnected pieces of work with but little correlation.

Their chief function should be that of affording an opportunity for carefully prepared discussions on subjects lying near the boundary of our knowledge and ignorance. Such discussions should be considered incomplete unless they led up to definite suggestions for new investigations.

The contributed papers should be considered from the point of view of their power of stimulating broad discussion or leading to suggestions for further work as well as their actual contributions to new knowledge. It is satisfactory to note that in some cases steps have been taken to approximate to this ideal. Of late years the British Association has organised and conducted joint discussions between its different sections on previously announced subjects guided by introductory papers, and this has had a most useful and stimulating effect.

The Faraday Society has also for some time past adopted the same plan. Their meetings have usually opened with a paper or papers contributed by authors especially conversant with the subject, summarising the existing state of knowledge and making suggestions for new departures.

Sir Robert Hadfield, the President of the Faraday Society, has mentioned that on one occasion no less than ten papers by authors of different nationalities were printed and circulated as a basis for a discussion.

The discussions at the Engineering Societies are frequently quite as useful as the papers on which they are started. The Royal Society still maintains the time-honoured custom of presenting at each meeting a group of papers of diverse character read in brief abstract to a very mixed audience of experts in many different subjects, by whom there is seldom any discussion worthy of the name.

Many of these papers would serve to stimulate better discussion if read before the special societies.

Having regard to the definition of the objects of the Royal Society in its charter—viz., that of promoting natural knowledge by experiment, it would probably not be inconsistent with that aim if time could be occasionally given to general discussions as to the direction experimental research should take in particular departments of knowledge, so that workers might be guided and a right direction given to their thoughts.

The chief function which any of these societies should fulfil is that of exciting the originality of experienced investigators and leading them into new lines of thought. Hence at the beginning of each session their councils should carefully lay their plans and divide up the available meetings between subjects of importance. They should secure from leading investigators introductory

papers, send out abstracts of these, and follow them up by short contributions from known specialists with the endeavour to focus discussion on essential points.

But something more than this is necessary. We have to formulate in precise detail the suggestions for future work, and bring them to the notice of those who may be able or willing to work them out.

The White Paper, which was issued last July by the Board of Education, signed by Mr. Arthur Henderson, seems intended to bring into existence some machinery for effecting this desired end.

So far as the "Scheme for the Organisation and Development of Scientific and Industrial Research" outlined in this White Paper is formulated in detail, it appears to consist in the establishment of (i) a committee of the Privy Council, which will be responsible for any expenditure voted by Parliament for scientific and industrial research; and (ii) a small advisory council, composed mainly of scientific men and men actually engaged in industries dependent upon scientific research.

The primary functions of the Advisory Council are stated to be to advise on—

(1) Proposals for instituting specific researches;

(2) Proposals for developing or establishing special institutions for the study of problems affecting particular industries.

(3) The establishment and award of research studentships and fellowships.

It would seem almost essential that in any case such council should have on it not only experienced investigators in pure science, but men of wide practical experience in technology and applied sciences.

The field of scientific and technical work is now so large that almost every scientific worker, even of great eminence, is necessarily more or less a specialist. It would be almost impossible for a council of a small number of members to include sufficient ability to deal with all the very different questions which will present themselves for consideration.

It requires expert knowledge to be able to judge of the value of a suggestion for new work. A physicist, however eminent in his own department, might be quite unable to say, from his personal knowledge, whether a certain proposal for new researches in metallurgy was worthy of attention and trial or not. An expert metallurgist might be able to pronounce it old or useless at once. In the same way a chemist, whatever his chemical knowledge, would probably be quite incapable of giving a useful opinion on proposals concerning researches in electrical engineering or telephony.

The White Paper tells us that it is contemplated that the advisory council will work largely through sub-committees reinforced by suitable experts in the particular branch of science or industry concerned on which it would be desirable to enlist the services of persons actually engaged in science, trades or manufactures.

It is clearly impossible for any single board composed of a few men, however eminent, to deal in any reasonable time with all the research problems awaiting solution in physics, chemistry, inorganic, organic and technical, metallurgy, engineering, electrotechnics, bacteriology, agriculture, etc., and the questions concerned in the recovery of our trade in dyes, drugs, glass, ceramic ware, ferro-alloys and scientific apparatus.

Hence separate bodies of experts will unquestionably be required to deal with the different subjects in order to bring to bear upon them the proper technical knowledge and to guide research on the right lines.

But now, if this is the case, the question at once arises: Why is it necessary to create a new machinery for dealing with these matters? Have we not already in the councils of our learned and technical societies, or in committees of their members, all that is required to form these boards, which might be called Permanent Advisory committees on scientific research? Why is it considered necessary to create new committees?

The proposition I submit for your consideration is that the organisation of scientific research should be a matter undertaken by scientific men themselves, and should not be taken over independently of them by a Government Department. The essential matter is that this organisation of scientific research should not become bureaucratic or academic, but should be conducted by bodies representative of the best technical and scientific opinion, and be closely in touch with the members of all the various scientific and technical societies. If these permanent advisory committees in the different subjects were elected from the councils or members of the various societies, we should have in them men who are closely in touch with those particular branches of pure or applied science. Who, for instance, can better prescribe the requirements in the way of research in pure and applied chemistry, or in engineering or

electrotechnics, than the leading members of the various existing chemical and engineering societies?

If public funds are to be administered, then it might be proper that certain of the members on each board should be appointed by the Government Department concerned, say, by the Education Department; but my contention is that the organisation work should be the work of scientific men as a whole and not any small section of them, or be carried out by Departmental officials over their heads.

In order to make my suggestion perfectly clear let me apply it in particular to the case of those learned societies especially concerned with experimental research or invention, such as the Physical and Chemical Societies, the Society of Chemical Industry, the Institute of Chemistry, Faraday Society, the Institutions of Civil, Mechanical, and Electrical Engineers, and so on. My suggestion is that each of these, if they have not already done so, should form a strong but small research committee of their most eminent original investigators in them. This selection should be determined by the votes of all the members, and regard should be taken of nothing but real originative ability, as exhibited by past achievements. There should be time limits for serving on this committee, so as continually to bring fresh young minds to bear upon the work. The Royal Society should put itself at the head of this work, and be the superior director of it all.

Suppose, then, we assume that we have created permanent advisory committees for the different branches of pure and applied science, the duty of which should be the organisation of research in their respective departments. Their first work should be to draw up as comprehensive a report as possible, pointing out the general needs of each department of knowledge and the most necessary directions of research in it.

The first report would no doubt have to be concerned chiefly with the deficiencies in the appliances and means of conducting it, such as laboratories and apparatus; also with the numbers and supply of men available for undertaking it or actually engaged on it.

Subsequent reports would then be properly occupied with the more detailed discussion of the problems awaiting investigation and particular suggestions for directions of research. Each advisory board should have its salaried recorder or secretary, who should be a scientific man with some literary attainments. Each board should, of course, have taken evidence from all kinds of experts in its own subject in drawing up its report, so that this document would then be not the mere embodiment of the opinions of a few, but the concentrated wisdom of all those engaged in the same field of work. Such reports, if made annually, would come to possess immense value and form a solid basis for suggested practical reforms.

These advisory boards would have then to be supplemented by some means for carrying out their suggestions into practice. We have to create a more definite professional status for the scientific investigator in pure and applied sciences, so as to push forward research in a more systematic and less casual manner than at present. Scientific research has to be elevated to its proper position as a profession quite comparable in importance with medicine and law.

Deferring for the moment some remarks on the special training for the work, suffice it to say that we must not only have a large increase in the number of the workers undertaking research, but must make it possible for a capable man to give himself to it by providing suitable stipends and inducements.

As far as regards pure science no plan seems better than that of creating an increased number of research scholarships and fellowships which shall enable a properly trained and competent man to give his whole time to such work and to earn a reasonable living by it.

Hitherto it has been largely done as a voluntary matter by university and college teachers in the intervals of teaching work or in odd moments and vacations. Such scholarships should run on the lines of the 1851 Exhibition scholarships, which have done good service, and should be of the value of £150 to £200 a year or more.

They should be annual appointments renewable on a consideration by a competent committee of the work done in the year, so as to safeguard against inefficiency or laziness.

The research students should not be left to do what they please, but should carry out the suggestions and recommendations of the above-described consultative boards.

It is a more difficult matter to arrange a scheme for industrial research work and to provide the men capable of doing it. Here we are directly concerned with knowledge or trade secrets which may have a large pecuniary value.

It is a common accusation that British firms concerned with scientific manufactures have not availed themselves of scientific expert assistance

to anything like the extent that Germans have done. Some scientific men attribute it to the want of foresight and insight on the part of the manufacturers, and some manufacturers assert that it is due to the unpractical character of a good deal of such scientific advice. The truth probably lies between the two.

There is a vast difference between the mere discovery of scientific facts and principles and the application of these in technology, where the prime question is cost and profit.

A laboratory chemist need take no account of the cost of fuel or time, he is concerned only with chemical actions; but in chemical manufacture a brilliantly successful laboratory reaction might be quite out of question as a practical matter merely on the score of fuel cost or labour, or the impossibility of securing a continuous supply of some material.

Hence the college training that may be sufficient to launch a successful investigator in the realms of pure science will be quite incomplete as regards a researcher in industrial applications unless coupled with a wide experience in factory processes and costs.

Then, again, there are certain difficulties in connection with industrial research that have to be considered.

Assume, for instance, that a trained scientist is taken on at works to investigate certain questions. He must necessarily be placed in possession of confidential information. Suppose that he makes some important discovery or invention of great pecuniary value to his employers. To whom will that improvement belong? The employers may say that without the opportunity to acquaint himself with the problem to be solved the investigator would have never made his discovery. The investigator might say that without his brains the employer would never have found the improvement.

Again, suppose that the scientific investigator does very little to help his employers, still, on the other hand, he may have acquired very important information which may make it inadvisable to let him place his services at the disposal of rivals.

Some of these difficulties have been mentioned in a report prepared by Mr. T. Ll. Humberstone, Mitchell Student of the University of London, issued as a special pamphlet by the Board of Education. This report deals with the scheme of industrial research fellowships devised by the late Professor Robert Kennedy Duncan for co-operation between universities and scientific industries which has been put in operation in the United States in the universities of Kansas and Pittsburgh.

Time does not permit me to quote extensively, but, broadly speaking, the plan is as follows: Men who have graduated with distinction and exhibited capacity for original research are nominated by the university as research Fellows. Manufacturers who are concerned with scientific processes are invited to state in strict confidence and in detail to the university certain particular scientific difficulties or problems in their work which they wish solved. They then enter into a contract with the university to pay for a defined time the stipend of a research Fellow and certain fees, and to give a bonus or royalty to the said investigator if the problem is satisfactorily solved. The Fellow, on his part, binds himself by contract to secrecy and undertakes to apply for patents if required on behalf of his employers and to certain other covenants. In this manner the interests of all parties are united.

The manufacturer has placed at his command the resources of university laboratories and libraries and his expenditure is strictly limited. The investigator has an inducement to do his best and a stimulus to diligence and preservation of reputation. The university is benefited, and, in many cases, as an indirect outcome of the solution of commercial problems, valuable contributions to pure scientific knowledge are obtained. The research Fellows gradually gain experience in industrial research which makes their work progressively valuable.

Some such scheme of profit-sharing is undoubtedly the fairest, and the best to couple together the interests of all parties.

It has sometimes been suggested that the State should make pecuniary rewards for scientific discoveries or inventions, but this is not a very practicable proposal. It is extremely difficult in most cases to appraise the value of a scientific discovery or invention in its early years, and in the next place there are pieces of scientific work the real value of which does not appear until long after the death of the originator.

Who, for instance, could have set a value on Faraday's discovery of induced currents or magneto-electric induction, when in ten days of intermittent work at the Royal Institution in the autumn of 1831 he gathered in new knowledge of surpassing importance to mankind? These facts had no apparent value at the time, yet their application has brought wealth in untold millions into the exchequer of nations.

I remember speaking, shortly after Clerk

Maxwell's death in 1879, with an eminent Cambridge mathematician concerning Maxwell's great paper published in 1865 "On the Dynamical Theory of the Electromagnetic Field." He told me in all seriousness that the impression produced on his mind by this great paper was, that it was one of the most exalted productions of the human intellect. Yet it was twenty years, and long after Maxwell's death, before this paper brought forth its fruit in Hertz's work on electric waves, and thirty-five years before we saw the final outcome of it in the achievements of wireless telegraphy.

How would it have been possible for contemporaries properly to give a value to that suggestive paper in terms of current coin?

I believe the only practical method of assisting scientific research is by a well-devised system of research scholarships, fellowships, and professorships, renewable annually or at longer intervals, and in any case held subject to productive work.

If we combine such a system with the above suggested advisory boards, there is a possibility of creating a workable system for the endowment and encouragement of scientific investigation which will be kept in close contact with practical necessities as well as with the most fertile regions of scientific thoughts. The important question is, then, the ways and means.

In the month of May last a joint deputation of the Royal and Chemical Societies waited upon the Board of Education, and later on it was announced that a Parliamentary grant of £25,000 per annum would be placed at the disposal of the Board for the purpose of research.

Whilst such a grant will do something if wisely expended, it can hardly be expected to carry out in its entirety any large and comprehensive scheme.

We have much leeway to make up, and a commercial competition in front of us in scientific industries which will tax our very utmost powers. The nation ought to be prepared to expend at least the cost of one battleship in the defence of our scientific industries.

Deferring for a moment the consideration of the training of the men to conduct it, we may consider in the next place—

II. The Provision of the Means for Conducting Scientific Research.

By this is meant the materials and apparatus required.

In early days these were simple and comparatively inexpensive. Much great work has been done with simple apparatus. Nevertheless, our modern scientific research requires, for the most part, costly appliances.

One rather startling experience at the outset of this great war was the discovery of the extent to which we had become dependent on Germany and Austria for these implements of research. We found that our sources of supply of chemical glass such as flasks, beakers, tubes, graduated vessels, and more complicated pieces of analytical apparatus were cut off. Also porcelain crucibles, basons, tubes and retorts, filter papers, and large numbers of research chemicals were not produced in England of the requisite quality.

Amongst pharmaceutical chemicals a very large number have been unobtainable, or obtainable with difficulty, since the war—such as salicylates, salvarsan, veronal and phenacetin.

My colleague, Professor Cushny, F.R.S., informs me that all the more complex synthetic chemicals, such as those used as indicators, stains in microscopic work, etc., have been obtained from Germany and are now unobtainable.

In physical and electrical work there has also been the same difficulty. Before the war we obtained many necessary materials from Germany which ought to have been made here. I instance such things as types of electric resistance furnaces for laboratory and assay work; cathode ray oscillographs and the proper type of electrostatic influence machines for working them; certain types of mechanical pumps for making high vacua; extremely fine wires of different materials necessary for thermo-electric ammeters for high-frequency current measurements in wireless telegraphy, and also special alloy wires for electrical resistances, and many other similar materials.

We were at one time even entirely dependent on Germany and Austria for electric arc carbons, and only the enterprise of one British firm saved the situation. We are even now in difficulties as regards some electric fittings and appliances.

As an instance of the way in which the Germans look forward and anticipate the future, we may note the case of tungsten ore. When, after prolonged scientific researches, the metallic filament electric lamp made with drawn or pressed tungsten wire had ousted the carbon lamp, and when the immense importance of tungsten-steel had been recognised for high-speed tools and magnet manufacture, German interests set to work to secure the control of sources of supply of tungsten, even within the British

Empire. One of the chief sources of supply of wolframite, an ore from which tungsten is obtained, is in Burma, which produces about one-fifth of the world's supply. Before the war the Germans used to secure nearly all this ore and carry out the reduction in Germany. Consequently, when the war broke out there were few or no reduction works in England capable of supplying tungsten or ferro-tungsten.

In spite of this extremely valuable tungsten supply in Burma, which is the largest mineral-producing province of India, the local government was not provided with any mining expert who could have advised them in this matter.

It is satisfactory to note, however, that steps have been taken to remedy the state of affairs. The Lieutenant-Governor, Sir Harcourt Butler, visited Tavoy, the centre of the industry, last December and addressed the Chamber of Mines. He urged the concessionaires to do all that was possible to obtain the wolframite required at present for the making of munitions, and represented that if private owners did not meet the British demand, concessions would be cancelled and the Government would take possession.

Nevertheless, the Germans have already provided themselves with large stocks of this valuable material, without which it is impossible to make modern high-efficiency incandescent electric lamps or high-speed cutting tools for engineering work.

This is only one out of many instances which might be quoted to show our extraordinary want of scientific foresight in allowing absolutely essential materials to be taken by Germany both before and during the war.

This partial famine in essential scientific materials and apparatus is not due to any real want of scientific ability on the part of British inventors or manufacturers. It is due to causes which are very deep-seated. For one thing, our easy-going national temperament has found it less trouble to buy from abroad than make for ourselves. Labour difficulties, our fiscal policy and other causes have rendered it difficult to compete with German prices.

Above all, the mistakes and ignorance of politicians who allowed themselves and others to believe that there was no real danger of a rupture of peace, and that Germany's tremendous preparations for war had no other object than defence against sudden attack by jealous neighbours, acted like an opiate on our spirit of commercial enterprise and dulled our instinct of self-preservation.

Meanwhile it is to be hoped we are now awake to facts, and that scientific men, manufacturers and our statesmen will unite in remedying the present serious condition of affairs.

With respect to the supply of laboratory materials, it is satisfactory to know that since the war began considerable progress has been made in manufacturing in Great Britain some of the scientific apparatus which formerly came to us in large quantities from Germany and Austria. At the outset of the war the Society of Chemical Industry and the Institute of Chemistry of Great Britain and Ireland addressed themselves to this question. I am indebted to their respective secretaries, Mr. C. G. Cresswell and Mr. R. B. Pilcher, for kindly furnishing some information.

A glass research committee was appointed by the Institute of Chemistry under the chairmanship of the late Professor Meldola, and by April, 1915, eleven working formulæ for chemical glass had been produced and distributed freely to British glass manufacturers. They include a formula for miner's lamp-glasses, a glass highly resistant to drugs for pharmaceutical ampoules and glass for X-ray bulbs. We have also made considerable progress in producing certain types of optical glass.

The simpler glass chemical vessels can now be made here at prices which compare favourably with German pre-war prices, but there is still some difficulty with the more complicated apparatus requiring stopcocks. Filter paper as good as any foreign make is now produced in this country.

Two leading hardware firms have turned attention to the production of chemical porcelain apparatus, crucibles, evaporating basins and so forth, and before long it is to be hoped we shall be quite independent of Germany.

Now the question is—are we going back, when peace returns, to the old easy-going habits of importing German-made scientific apparatus? Surely the answer is No! a thousand times No! But unless we wish Germany's crime-stained hands to take back in commerce what she has lost in war we have to create and maintain an entire scientific and economic independence of our own. For this purpose we need, for one thing, a properly complete Scientific Intelligence Department.

The different agencies, committees and institutions which have been endeavouring to supply scientific information as to manufactures should have as their resultant a single organisation, the function of which should be to collect and

distribute all possible information concerning the mode of manufacture and cost of production and information concerning the patent position, if any, of all the appliances and materials used in scientific research. Such a scientific intelligence and information bureau might need subsidising at the start, but it might be possible later on to make it self-supporting by the subscriptions of firms and persons who desired information on particular matters. Just as one can pay a fee to a patent agent to conduct a search for anticipations on some particular subject, so this information bureau should have as its object to collect and supply to its subscribers all possible information concerning the manufacture or supply of the materials and implements of scientific research. This bureau might have certain laboratories or workshops attached to it where information could be tested and specifications issued for the manufacture of the materials and appliances used in research. It should not be concerned either with actual trade manufacture or with researches *per se*, but should enable anyone to find out with the least expenditure of time the exact way in which certain scientific materials or instruments are made and under what conditions they can be produced, and to supply this information to the trades concerned who are its supporters or subscribers.

There are already the beginnings of such a scheme in the information published by the Institute of Chemistry on reagents for analytical purposes prepared by a special committee appointed by the Institute and by the Society of Public Analysts and other Analytical chemists.

There is also an association called the British Laboratory Ware Association, formed by various firms to stimulate the production in this country of various laboratory requisites hitherto mainly produced in Germany.

It is desirable, however, to avoid the multiplication of too many separate associations and to concentrate into one agency the means for furnishing all necessary information and intelligence required to make British scientists independent of supplies from enemy nations.

The means that shall be taken to prevent this nascent national production of the materials of research from being killed by subsequent German competition is a question to which our political economists and statesmen must address themselves very seriously. It is only a small part of the great problem of our *post bellum* commercial policy in relation to the British Empire and our Allies, but the consideration of it lies beyond our present purpose.

We have then to consider—

III. The Training of the Men to Conduct this Scientific and Industrial Research.

Whilst the highest achievements in scientific research and invention must always depend to a great extent on that indefinable quality we call genius which cannot be made to order, it can hardly be doubted that much can be done to foster and assist it.

The nation must be educated to see that the men with high scientific and inventive ability in it, not by any means too numerous, constitute a national asset of inexpressible value. This power, when it exists, should not be allowed to dissipate itself in a struggle to secure the means of living, but be given an opportunity for the fullest exercise and use. There can also be no question that we have it in our power by suitable methods of education to develop such nascent ability.

Our present systems of education, and particularly the system of written examinations which are dependent so much on good memory for success, do much to destroy originality.

In spite of all that has been written and said on this subject, we do not seem to be nearer to essential reforms. The object of all education is threefold: first to train character, will, and that power of selecting the best amongst various courses of action which we call right judgment; secondly, to impart necessary information and ability to do certain things well; thirdly, to develop initiative and the power of handling new problems or investigations, and a certain alertness in dealing with new situations. Our present methods of education are far too much directed to supplying ready-made and peptonised information.

The great outstanding fact in modern life is the degree to which the energies and materials of Nature are employed to overcome the difficulties created by the increase and concentration of population.

We have to make the earth bring forth her increase at a greater rate to supply the ever-increasing necessities of growing populations and the many artificial wants which have been created by progressive human desires.

Hence an absolutely essential part of any complete education is some knowledge of science, and especially of its influence on the welfare of mankind.

Yet the people we put in a position of authority over us are, for the most part, not only ignorant of science, but not even interested in it.

In our public schools we train boys chiefly by directing their attention to words in the form of the grammar and literature of two dead languages, and we neglect to give them any wide and sufficient knowledge of things—viz., the physical phenomena of the Universe in which they live.

Is it, then, any wonder that when these boys grow up and take their places in Government offices, in the Law Courts or on the Press, or any other influential position, they are oblivious to the last degree of events taking place in the world of science which have in them the power to make or destroy national industries or affect the living of large populations? The destruction of the madder industry of France and the indigo industry of India by German synthetic chemistry are now old and familiar stories.

The point, however, to notice is that the scientific chemical discoveries were not allowed to remain mere laboratory feats. They were transformed into successful commercial enterprises. The Badische Anilin und Soda Fabrik is said to have expended £1,000,000 and taken seventeen years' work in translating Baeyer's scientific synthesis of indigo into a factory process. But the result has justified the foresight of those who expended it.

In an article in the *English Review* for January by Mr. H. L. Heathcote, on the "Chemical Industries of Germany," it is stated that in the year 1896 India exported natural indigo worth £4,000,000, whilst in 1913 this had dropped to £70,000, or under 2 per cent. of the export in 1896, as the result of Germany's manufacture of artificial indigo, which began in 1897.

This is only one instance out of many which could be quoted to show the blows that can be inflicted in this industrial warfare, the weapons in which are not shot and shell, but scientific discoveries and inventions.

The supremely important question is: What are the steps we are taking to train the men who will enable us to hold our own in this commercial conflict?

It avails nothing to point out that the beginnings of many of these achievements were laid by British scientific discoveries or original suggestions.

A truth or a suggestion which is not followed out or pressed to the point at which it becomes practically productive, is like a seed which is not planted in the ground. The intellectual perception of a truth or principle requires behind it the driving force of character and will if it is to pass into the useful stage.

When Mr. Edison found the clue to success in his attempts to make a talking machine, the story runs that he locked the laboratory door and, putting the key in his pocket, said to his assistants: "We none of us leave this room until this thing speaks." When, after hours of labour, the infant phonograph uttered its first little sentence its constructors were allowed to proceed to their long-deferred refreshment. Very few people are aware of the steady pushing and expensive work which had to be done before laboratory experiments on electric waves were converted into practical long-distance wireless telegraphy.

Some people might be inclined to ask why there should be this competition and pressure to invent? What difference does it make who discovers a new fact or makes a new application?

If scientific knowledge were a mere matter of intellectual curiosity concerning the secrets of Nature it would not matter much, except for national honour, who made the discoveries or applications. But scientific knowledge has become much more than this. It has become the means of increasing national wealth, and also by which national wealth can be taken away. Again, in virtue of our patent laws, it has become possible for alien inventors to prevent us from even using in our own country in particular ways the waste products of our own industries, as in the case of certain coal-tar products.

Hence scientific knowledge can be applied so as to become a tremendous weapon of destruction as well as of national strength.

It is for this reason that we require men to be trained not merely to make scientific discoveries, but to make useful commercial applications of them which are wealth-producing or wealth-conserving in a national sense.

This requires a peculiar combination of scientific ability and commercial insight, and it is just here that Germany has the advantage.

Mr. Lloyd George said on one occasion that he feared Germany's war-bread spirit, by which he meant the willing subjection of a whole Empire to discipline. We might say, with even more truth, that what is to be feared is Germany's militant chemistry and engineering, or that combination of organised and commercialised science which is relentlessly applied without any moral restraint to undermine and take away sources of power of other nations.

This, however, is what we have to meet. We have to train chemists, engineers, electricians and physicists who are not only learned in the knowledge of their science and originative in discovering new facts and principles, but have also a keen commercial sense which directs them to the solution of the practically useful problems.

We have, therefore, to create a very much closer union between industry and science.

To some scientific men this seems derogatory to the dignity of science. On the other hand, men concerned with the business side of manufacture are apt to undervalue the aid which science can give them. Meanwhile our scientific industries suffer from this dissociation.

In the first place we should aim at bringing about a much more intimate relation between the universities and technical colleges and the factories and workshops, so that the college teaching may result in producing a type of man more useful in the factory. For this reason I am an advocate of the so-called sandwich system, by which the student spends a year alternately in the shop or factory and in the college, the first and third year being at the college and the second and fourth in the shop or factory. This turns out a better type of man than two years at the college and two years in the shop taken consecutively. It should apply not only to engineers in all branches, but to chemists as well.

Then, again, conferences should be held from time to time between teachers and practical engineers and chemists for the exchange of ideas on the subject of the schemes of work and study to be followed by the student-apprentice, so as to turn out all-round men and not unpractical theorists or unscientific practists.

We have to improve in many ways our college teaching, so as to expend to better advantage the available time and place more stress on ability to use information than to store it.

One result of the war and of the economic pressure which will follow will no doubt be to diminish the time given to amusements and games at both schools and colleges. There will be a more intensive interest in intellectual matters. The inclusion of military training as part of school education will create a more disciplined type of schoolboy and more zealous college student—and we shall be able to advance matters a stage, so that things now taught to first-year students at college will be learnt at school, and things which were only learnt after leaving college will be taught there in a third year.

Engineering and chemical students should be brought much earlier than at present into contact with questions of cost and estimates, so that they may know not only how and why a certain machine works, but what it costs to make it or to run it. They will then be far better able to take advantage of the workshop training and obtain earlier that "workshop sense" or instinct which looks at everything from the point of view of cost and profit, as well as operation or efficiency.

We have before us a tremendous task to restore the waste of this great war. To do this we have to utilise all waste products and to abolish waste and inefficiency in all departments of life, domestic, commercial, political and industrial, and we have to get rid of them in scientific work as well.

We can only do this by bringing to bear the scientific method upon all these regions of activity and even upon scientific research itself. As a small contribution to this work the above suggestions are tentatively put forward, and with the greatest diffidence I submit them now to your careful consideration.

DISCUSSION.

MR. JAMES SWINBURNE, F.R.S., in opening the discussion, said the first thing a traveller ought to settle when setting out on a journey was where he wanted to get to. In the present instance, there were two or three objects in view: first, the recovery of England and the Allies economically; secondly, the further suppression of Germany, which was a different proposition altogether, and which might be exclusive of the first, *i.e.*, this country might be itself in considerable difficulty in trying to hurt Germany economically after the war; and, thirdly, whether they desired to secure the independence of the nation, *i.e.*, to manufacture everything in the nation for economic reasons or with a view to providing for another war. If science had been neglected in England, in his opinion the science of economics, which was by far the most important for the nation and for the public, had been neglected more than any other. Some men did not mind exporting cotton to Germany, because they said that if the export of cotton was stopped the Germans would make gun-cotton out of wool; they also said it was no good stopping lard and oils going into Germany, because that country now had command of Galicia and could get all the oil it wanted from there. Such people could probably easily be persuaded that their chemistry was very groggy indeed, and after argument would admit that they were talking nonsense; but when men expressed the latest lunacy on economics that they had obtained from political papers

no power on earth would persuade them that they were talking nonsense. Most people seemed to assume that economics was not a science, and that the mere casual reading of a halfpenny paper would put them in a position to discuss the most complicated problems. A confusion also arose in the discussion of the subject dealt with in the paper between what was good for us as a nation and what was good for mankind. Scientific work generally was good for mankind, but research did not necessarily do the nation any good unless the information gained was kept exclusively for the nation. If a discovery was published in the journals of this nation, and another nation, which was a good copyist, made use of it, he did not see how it helped this country, nationally, at all. He had some compunction in saying anything that sounded like criticism of the author, because he (Mr. Swinburne) realised that Dr. Fleming was one of the most practical of our scientific men; it was not generally realised that this country owed the National Physical Laboratory to him. But in his opinion there was a general confusion between scientific research, industrial research, and invention—three things which were absolutely different. Men who carried out scientific research were not considering the commercial importance of the different elements, but simply desired to complete a huge organised structure of knowledge. But the man who carried out industrial research was not concerned with that question at all. He did not want to know anything in particular except how to improve something so that he could develop his particular industry. Invention was a different subject altogether, involving a different type of man. The scientific man who made researches was not the least likely to be an inventor, although he might be on occasion. The author of the paper was a good example of that. There was a general tendency in this country to say that our industries were not scientific. That he believed was a calumny. He knew something of the industries of the country, and he thought they were about as scientific as they could be. It was always said that England had a kind of national diffidence, and that it was the only country that ran itself down. He believed Mark Twain said that England was mentioned in the Bible, because the statement was made: "Blessed are the meek for they shall inherit the earth." But that national diffidence might not really be diffidence; it might be individualism as contrasted with collectivism. The vanity of a country which prided itself on its so-called patriotism took the form of saying that everything in that country was perfectly good. This country, on the other hand, was individualistic and did not do that. Each member of the community said: "I am very good, but the rest of the country is awfully rotten." But the curious thing was that the people who said that the country was rotten in various ways were not really the people concerned. For instance, many people said that the present war was being conducted in a perfectly fatuous way, and it was only necessary to read the papers to find articles by novelists and clergymen showing how the war ought actually to be run. He did not wish to compare the author either with a novelist or with a clergyman; but he wished to emphasize the point that the accusations of want of science which were made against British industries were not made by scientific people who were engaged in industry, or who had anything to do with it; they were made by the scientific people whose business it was to educate students, *i.e.*, by the professors of the various universities. He did not want to be disrespectful to such people at all, but he did not think they knew much more about industry than the novelist and the clergyman knew about the war. He also wished to point out that research as research could not be national; it could only be for the good of the world at large, because it was practically impossible to keep it peculiar to the country. He heartily agreed with the author that any kind of research in the hands of the Government was quite useless. To begin with, a committee of any kind was utterly useless. Many present had spent much of their lives on scientific and other kinds of committees, and knew how bad they were; but those who had ever been on Government committees knew how infinitely worse they were. It was possible for a man who was on a committee to do something in spite of being on that committee, but he could only do it as a strong man, struggling against difficulties, outside the committee. He thought the suggestion made by the author in regard to research students was not likely to be very practical. Pure research work, while useful, was very dull and uninteresting, and he did not think many students were likely to undertake it. It might succeed by mixing up scientific research with industrial research, but that type of student was the least likely of all to invent anything. Personally, what he thought was required was, firstly, that students should be trained in economics at school as one of the fundamental things that everybody ought to know something about; secondly, that the State should never be allowed to lay its deadening hand on any industrial advance; thirdly, that students should be trained at college not in technology so much as in principles, obtaining as much scientific training as possible from people who were able to impart such knowledge, and then do their research work in the works afterwards. That might take a little longer time, but it would certainly produce better results. He did not know whether it was possible for the college laboratories to be placed at the service of industrial concerns. He understood that the function of a university was to teach students, and the author's suggestion would commercialise the universities by using them for other purposes. Universities were at present largely used for pure research work, which was very interesting for the professors but did not necessarily teach students, and if they were going to be used for industrial

research work he thought the training of the students, which was the first thing the universities were supposed to do, would go to the wall. Finally, he suggested that the Patent Laws should be entirely remodelled, not by a number of politicians, patent agents, and patent lawyers—although each of those classes would have to be consulted—but chiefly by people who industrially used patents and by inventors.

SIR WILLIAM A. TILDEN, F.R.S., said that many of the propositions laid down in the paper required a great deal of further consideration before he could safely pronounce a definite opinion upon them. This country suffered to a large extent from the curious national indifference to what had been called "things of the mind." The British were not an intellectual people; they had been occupied too much in the past in other ways; but they had now received a horrible shaking up and were beginning to turn over a new leaf, which it was hoped would lead to a reform in the future. But the reform must begin at the top, and for that purpose it was necessary to see that the composition of the House of Commons was altogether changed. At the moment he could think of only one accomplished and eminent man of science who occupied a seat in that body, and it always seemed to him that the time of Sir Joseph Larmor was entirely wasted by sitting in that assembly. Half the Members of the House of Commons ought to be as well educated in subjects of physical science as the other half were educated in the old classical manner, so that the absurd mistakes that were made, both in speech and in action, by Ministers who were responsible for the conduct of the affairs of the country should not occur. But more than that was required, namely, a reform in all the offices in Whitehall. He remembered ten or eleven years ago Mr. Haldane, in an after-dinner speech, said that when his party got into power a substantial proportion of scientists would be put into every office in Whitehall; but when his party did get into power he (Sir William) did not see much change in the composition of the higher members of the staff, and they seemed to preserve the same attitude towards scientific questions. Some new offices also needed creating, particularly one which should be in closer touch with the applications of science to industrial affairs than was the Board of Trade at the present time. Personally, he deprecated any steps being taken which might lead to a diversion from their proper employment of men who were capable of making discoveries. If scientific people were grouped together, one group being able to investigate one subject and another another, no doubt a considerable commercial success would be met with, because that was the sort of system which prevailed in the German chemical works. Personally, he wished to look at the question of research from a broader point of view. If the history of physical science was gone into, it would be found that all the really great advances in fundamental principles had been made by the English and the French. Faraday, at the end of his days, had only an income of £300 a year in addition to a house at Hampton Court lent him by the Queen, but he was quite happy with what he had. So he believed was the really inspired discoverer, who did not undertake his work with a view to making a fortune, but with that kind of divine curiosity which led him to look closely into the features of Nature. It was that which had inspired British people in the past, and which had achieved such satisfactory results; so that, although he believed the councils of the learned societies would willingly lend themselves to assist in the process of organisation, he could not help feeling some sympathy with Mr. Swinburne's query as to what would come of it. The council of the Chemical Society could meet and discuss and formulate a good many useful rules, but he was not quite sure how much would come out of it. This country had suffered in the past from the intrusion of the non-expert into the expert field. One important question, deserving of the closest consideration, was how the young men who appeared to be properly qualified to undertake research were to receive the sort of experience they required to make them understand industrial problems. He was not quite sure how far the scheme of sandwiching, to which the author had referred, would be possible in connection with chemistry, although he believed it had worked satisfactorily in connection with engineering. He felt that the Germans had settled that question for this country on a practical scale. In Germany university graduates, who had been thoroughly instructed in the principles of various subjects, were taken into the works under contract for a certain number of years; they were paid a salary which was sufficient for them to live upon modestly and they had a prospect before them. It was that prospect which entered so largely into the vision of the young man. In this country it was very difficult to know how far to encourage a clever young fellow, at the end of his graduation, to go on with scientific work, because he immediately said: "What will it lead to?" If he were offered a scholarship or fellowship for two or three years, unless a scheme could be arranged by which the fellowship was of a progressively increasing value as time went on, so that there was a sort of profession for him to look forward to, he did not think the best of the men would compete for such a fellowship. He hoped the eminent heads of industrial concerns would take rather more interest in the matter than they had shown up to the present. On occasions such as this he would like to see one or two big manufacturers present, who would state in plain language what their views were as to the possibility of turning to more practical account the scientific resources of the country.

Dr. H. S. Hele-Shaw, F.R.S., said he was deeply interested in the question of the student and the relation of the professor to the student. He was not a professor at the present moment, as he had been actively engaged in the pursuit of the engineering profession for the past ten years, but the best part of his life he had spent as a professor, so that he was able to look at both sides. Owing to the enormous development of technical colleges and local universities, the professor in this country was at the present time more largely engaged in promoting research than any other individual, but there were three things with which he was confronted: firstly, with the choice of the subject, because the student almost always appealed to him; secondly, with the advice he had to give as to the method in which the research was to be carried out; and thirdly, and most important of all, with encouraging the student to continue the dreary work of research. Personally, he did not believe in results which were quickly attained. There was such a thing as luck, and some men seemed immediately to hit on an idea which made them famous, although such instances were very rare. The major portion of research work was of a dry, dull and plodding nature. At the present moment research was hopelessly mixed up with invention, but those who had worked at both knew the difference. The paper gave a very clear idea of the difference between invention and research, and from that point alone would do much good. Many works did not feel justified in expending money, because they thought that the man who carried out the research would go away from the works having made some great discovery at their expense. He also desired to emphasize the importance of encouraging students to tabulate, not necessarily for publication to the world at large, all the work they had done which did not lead to any result. Much of that work was good work, and it ought to be possible to institute a committee of scientific men to encourage and reward the student for all the labour he had expended on it.

Dr. W. H. Eccles thought that many scientific men would agree that there was a possibility of the organisation of industrial research, but many of them would argue that there were some things which could not be organised. For instance, no one would propose to organise the fine arts. It was impossible to imagine a gathering of a great number of painters with the object of painting a fine picture. In the same way, it was impossible to get collaboration in literary work over any long period. In the higher reaches of science also, where inspiration and individual genius were the principal factors, one ought not to attempt to organise. Though such a scheme as the author had brought forward might be very appropriate for industrial research, it might be very harmful in purely scientific research. Those two complicating sides of the question had to be borne in mind in any discussion of the subject.

Professor William A. Bone, F.R.S., said that personally he was very apprehensive of research work, whether purely scientific or industrial, getting into the hands of committees. There were some questions on which a committee might be a help in guiding the research, but primarily research was carried out by independent people. He had had a good deal of experience of working with, and conducting researches for, committees, and he very rarely experienced the sensation of receiving ideas from those committees as to how the work was to be done. The work was usually left to the individual members. He saw a great danger in what he called specious schemes of scientific Socialism. He was a strong believer in the individualistic principle. If the people of this country desired to choke the progress of scientific discovery and invention, then such matters should be placed under the heels of committees.

Professor Henry E. Armstrong, F.R.S., said the general impression he obtained from the author's views did not appeal to him, and he would be more inclined to follow the views of Mr. Swinburne. Dr. Fleming had complained of the ignorance of politicians and of the public. Personally, he did not think the author had the slightest right to make those complaints, because they themselves were the authors of that ignorance in a large measure. Twelve or fourteen members were nominated by the Royal Society as fit and proper persons to serve on the governing bodies of various important schools, but they never met together; they were not associated in any way in that work; they were not asked to exercise any influence, and they received no instructions of any kind whatsoever. Sir William Huggins, who was very much interested in the problem, had brought the matter forcibly under the notice of the Society on several occasions, and a meeting of the public schools representatives was once held, but it came to nothing. So long as they were not organised amongst themselves, and had no policy which they could force upon the schools, they had no right to complain of the ignorance of the public and the politicians who came from those schools. He did not believe any improvement would be seen in Parliament after the war for one, two, or three generations. For the past thirty or forty years they had been to a certain extent slaying certain prejudices. The rising generation would start with a few of those prejudices gone, but with its own prejudices coming along probably. Unless the scheme of British education was absolutely reformed, he did not believe this country would make any progress. He quite agreed with the author in taking exception to the appointment of the new Advisory Council for Research. Dr. Fleming said that scientists ought

to do the work; and so they ought. They ought to have taken the work in hand long ago, but they had done nothing. An appeal had been made to the Royal Society over and over again to organise science as a whole, but the Royal Society would not listen to it, and until the Fellows of the Royal Society in the first instance were effectively organised as a whole, he thought no progress whatever would be made, not because he believed organisation would effect much, but because by organisation a new spirit would be brought into being. When the individualism of this country was organised the nation would be irresistible, but he did not believe they were going to do it. If it had not been done in the past one and a half years it would not be done in the next one and a half years, and they would forget all about it when the war was over. There were two kinds of research, the free-lance research and the directed research of industry with a definite object. The less the free-lance research was touched the better. What had been done in that respect in modern times had not been at all salutary; there had been too many committees at work and too much asking what subjects should be dealt with. As a teacher, he had always felt that what was wanted was that money should be available that he could be trusted with, and when he had a man who was competent to do work he should be put in a position to remunerate that man without being asked a lot of questions of what likelihood there was of something resulting from the work. If research could be helped in that kind of way, things would go ahead, but if it was necessary to appeal to advisory committees and Royal Society committees they would not get very far. The Germans had shown this country how to do directed research work, and, in his opinion, if we were not prepared to copy them we should do no good. Industrial work must be done under industrial conditions, for the most part in the works; and it was only when large problems which were common to the whole industry were dealt with in that way that good resulted. The real school for the training of men for industry in Germany was the works laboratory. The men were trained academically in the first place; then they went into the industry and got their chance. He believed there was a good deal of senseless talk about German methods at the present day. It was necessary to be philosophic in regard to such matters, and adopt the Japanese method of picking out what was good and applying the knowledge acquired in that way. He thought we had it within our power, out of our own knowledge, to do most of what was required, if boys were turned out from the schools prepared to receive ideas. He was not a believer in the statement that the English were not an intellectual people; he believed our disease was an acquired one brought on by the teaching in the schools, the only solution of which was to crucify or in some other manner get rid of most of the headmasters.

MR. WALTER F. REID, in supporting the last speaker's remarks, said that most young fellows in this country were taught more to play than to work; they left school with great ideas on games but with no scientific knowledge. He desired to emphasize the point that inventors were treated very badly indeed in this country. A chemist who went into an industrial works received a very small salary, and he was not encouraged by the firm to use his intelligence or his inventive genius in such a way that it would be of benefit to him: it was always a question of benefiting the firm that engaged him. The employers insisted on most iniquitous agreements being signed, prohibiting the chemist from benefiting in any way from any invention he might make when in the service of the firm. He knew, as Chairman of the Institute of Inventors, that nearly every month they were asked to advise on agreements of that kind. The matter required urgent attention, but he was afraid that, as Parliament was constituted at present, nothing would be done. More hopeful to him than anything else was the meeting recently called by the Lord Mayor, when seventy mayors from the chief cities of the country met at the Guildhall, and when the Lord Provost of Glasgow referred especially to what he called "all talk and no work." He thought if the heads of large towns and industries joined together they would be in a position to bring about the substitution of practical men for unpractical politicians. Since the war commenced a very great injustice had been done to many inventors. A number of industries were practically stopped, but those who had patents connected with them had to keep up their payments on them, because the Board of Trade refused to allow the patentees to postpone the payment of their fees until after the war. That was most grossly unfair: the Government would not help the inventor in the slightest degree. At a time when many people were searching for information with regard to the manufacture of new products that were urgently required, the Patent Office library was closed at four o'clock, although as a result of representations it was agreed that on one day of the week it should be kept open until six. That was very injurious to the country, and unless some society, such as the Royal Society of Arts, used its whole influence to alter such practices, the best use would not be made of inventions. The inventor ought to be encouraged, and not discouraged as he was at present.

MR. J. W. LOVIBOND, speaking as a scientific free-lance of forty years' standing, said he had limited himself to one particular line of investigation, namely, the analysis of light and colour sensations, but he did not wish the young people he had under his charge to be limited in that way—he wished them to have opportunities of a wider scope of education. On turning, however, to the handbooks dealing with the subject, he found that, although the refraction and reflection of light were

fully dealt with, colour was almost ignored. He found also that several conflicting theories were being taught by the different educational authorities, and that there was no common language or notation. That condition of things pressed very hardly upon the men who were defending us abroad at the present time. He held the view that aeroplanes could be rendered less discernible by scientific colouration, but he found there was a general impression amongst scientific men that it was so difficult that it was hardly worth while giving it a trial. On the other hand, he had sufficient evidence to show that a practical advance had been made in the subject.

Mr. L. Gaster desired to emphasize the point that if any Government Department was approached with a definite object in view, the matter was taken up in a practical way. Speaking from experience, he knew that the Home Office had taken up the question of illumination and lighting, which at one time was entirely neglected, and had now issued a most admirable report on the subject, which was a guide to those interested in the question not only in this country but in the rest of the world.

The Chairman (Dugald Clerk, D.Sc., F.R.S.), in proposing a hearty vote of thanks to the reader of the paper for his excellent contribution, said that he agreed with him to a certain extent, and he fully agreed with Mr. Swinburne in regard to the necessity of studying economics. There was no doubt that scientific men were weakest on the subject of economics and business, the business man being better informed on those subjects than the average scientific man. At the same time, he thought scientific men were at the present moment greatly overrating the danger of foreign competition. Sir George Paish, in a very admirable address he recently gave at the London School of Economics on the economic strength of Great Britain, said: "The British nation has never made the mistake of being too clever. The greatest qualities possessed by the British nation are common-sense and courage, combined with lack of imagination. Their foresight is confined to doing the next thing that presents itself. Each difficulty as it arises is dealt with either wisely or unwisely. Their great wealth has been built up by their inability to realise the meaning of the word 'danger,' either from a physical or from a financial standpoint. The British people are prepared to take greater risks than any other people in the world, and this quality has brought to them an income and a degree of well-being that can scarcely be measured." In 1903 the united income of the British people was about £1,700,000,000 per annum, and it had risen in the year 1914 to £2,400,000,000 per annum. The efforts of British business men were more successful than those of any other nation except America, and they resulted in greatly increasing the wealth of the country, so that the average income per head was £53 per annum. Competition with another nation was not a thing to be afraid of, and the prosperity of another nation was not a thing to be afraid of either. Some people, even scientists, seemed to think that all the nations of the world were sellers and not buyers. It did not follow that because a man was a discoverer of a new gas he knew anything about economics. People spoke as if all the nations were busy exporting goods to other places somewhere, not to other nations, but to some shelf outside the world, were cutting each other's throats to send the goods there, and were getting nothing back in return, or, if anything did come back to this country, it was "dumping." Even people of ordinary intelligence were horrified at the excess of imports into Britain over exports. That very fact was a measure of Britain's success, because the measure of success of any nation was the excess of imports over exports. A nation wanted to get back as much as it could for what it put out; but some foolish people would make this country receive only a very small amount of imports back. While he agreed with the author as to the necessity for looking into all the different matters with which he had dealt, personally he had no fear of competition from Germany or any other nation. Britain was thoroughly well able to give a good account of herself, because she was well prepared both in science and in industry. Scientific men often did a great injustice to themselves. He was glad to hear Sir William Tilden say that England and France were the principal scientific nations of the world, so far as discoveries were concerned. They were, and they were also the principal industrial nations of the world, England especially. He had no doubt that England would continue to be so, and the £4,000,000,000 which England had invested in foreign countries would be the greatest lever in her favour in the respect that she would always have both exports and imports. It was quite a misleading analogy to use the expression "war on industry." There was no war on industry. This country wanted everything that other people could give, and the other people wanted everything we could send them, and if any nation fancied they could send things to other nations without receiving goods back, the sooner they went to school and learned economics the better. The author desired him to say, in conclusion, that he would reply in writing to the various remarks that had been made.

The resolution of thanks was then put and carried unanimously, and the meeting terminated.

Sir Robert A. Hadfield, F.R.S., writes:—"Although fearfully rushed with war work, added to by the recent air raid, I have found a short time to glance through your paper, with most of the conclusions in which I am in hearty

agreement. I am confident you are on the right track in objecting to the formation and organisation of research by a Government Board. In order to obtain the best results we want to get away as much as possible from past grooves, which have not been particularly successful. I could a tale unfold of what I have of late seen in this respect, and am sure such an arrangement would not be in the best interests of the country. We certainly want, so it seems to me, not to be under academic or bureaucratic influences. As you rightly point out, there are excellent means for dealing with the matter already in existence in the shape of our magnificent technical societies and institutions, which are able to diffuse knowledge in a manner I believe not equalled by any other country, except perhaps America, which, being Anglo-Saxon, runs on our lines. If money is to be spent, why not place it in their hands to do freely as they think best? I am confident that more value would be obtained for the money expended. At any rate, let us give the plan a trial before running to bureaucracy and red-tape methods. I have, too, been very much impressed with a recent letter to the *Telegraph*, in which the writer, in the name of 'Efficiency,' advocates the foundation of a Ministry of Science. I believe with a Minister of Science and a Minister of Commerce this country would benefit enormously. Science is not merely high and dry knowledge, but is just as much subject as business itself to advance and progress by duly prepared and organised methods. The valuable work by the late Dr. G. E. Gore, F.R.S., 'The Art of Scientific Discovery,' a book not half sufficiently known, and which I have constantly quoted, shows this in an unmistakably clear manner. It deserves reprinting and placing in the hands of our educational authorities for distribution amongst those concerned. If you would find £100, I would give the same sum to pay for copies of Gore's book to be circulated far and wide in the proper towns. Dr. Gore's writings and suggestions have always had a great influence on me, and I think the book should be in the hands of everyone who is now studying how and in what way the progress of science is to be helped on. I hope this idea of a Minister of Science, for the first time I believe promulgated in the *Telegraph*, will be taken up in earnest; it is a splendid suggestion. Why not make the President of the Royal Society, Sir J. J. Thomson, the first Minister? As a Fellow of this Society I have for a long time seen and watched his work, which is of the highest, whether in thoroughness or originality. The attempt now made to obtain scientific progress by means of the Minister for Education is, I think, a mistake. The present occupant of that post is my friend, the Right Hon. Arthur Henderson, a man made for the times and nobly doing his duty for the Empire. He, and also previous occupants, would be the last to claim that they could adequately deal with the problems of 'science' as apart from education. No; we want a man for the post who will devote himself specially to the suggestion made by 'Efficiency.' This nation would greatly benefit if it were carried to a practical issue. Science and education are not at all the same: in other words, plenty of men are highly educated and yet they may not be scientific. How, therefore, can the wants of the scientific man be met through the ordinary educational channels? The co-ordination and organisation afforded by a Ministry of Science would be, so it seems to me, of the greatest possible value to this country. I trust, therefore, that this suggestion will be pursued and eventually carried into effect. Again let me say that the opinions expressed by you, with your great experience of both the highly scientific and technical sides, are invaluable. It is with the greatest regret that I shall not be able to be present at the meeting. It seems to me that your scheme is admirable, but it wants a head, and that head should be, for example, to quote what I hope may represent the future policy of this country, a Minister for Science, the first of whom, as I have suggested, might well and properly be Sir J. J. Thomson. Make him our first Minister, and with the aid of his many colleagues in the Royal Society, and other scientific and technical societies, there would be a marvellous development and increase in appreciation of science itself and in the application of science to industrial uses, upon which you rightly lay such important stress. I am also very glad to see the well-deserved compliment you pay to the Duncan scheme in connection with the Mellon Institute and the University of Pittsburg. In this, too, I feel confident there are germs of important development to the application of science to industrial purposes."

Dr. J. A. Harker, F.R.S., writes:—"I hope that the author's suggestions will be carefully considered. I was specially struck with two points mentioned: firstly, the need for more organisation in the compilation of the programmes of our learned societies with a view to the stimulation of increased interest in their proceedings, and in particular of the meetings themselves. In absence of information whether an author would be present to communicate his paper, one often felt hesitation as to whether it was worth while attending a meeting where perhaps the only paper on the programme of definite interest might easily be taken as read. Speaking as a Member of Council of the Faraday Society, I am sure that the method of organising occasionally a discussion on a definite subject, on which written contributions by specialists were invited, is one which had thoroughly justified itself in practice. On the evening of the discussion authors were only expected to touch briefly on salient points, since all the papers had been previously printed and circulated and speakers came prepared with their contributions. As Professor Fleming pointed out, this method of procedure, though rare, is not unknown at the Royal Society. Everyone who was present will

remember the discussion on the internal architecture of the atom opened by Sir Ernest Rutherford. Such occasions justify a long journey in order to be present and furnish to workers incalculable stimulus and inspiration. The second point was the need for better machinery for placing available information, the results of recent research, at the disposal of those needing it. I have been much impressed lately by this, and I could give many instances. A week ago a Government Department rang up the National Physical Laboratory on the telephone regarding an important war problem for the solution of which the Department proposed to institute immediate experiments at their laboratories. The writer found that though the data required had probably never been tabulated in the desired form, yet a short search and a few minutes' arithmetic enabled an answer to be sent back at once, thus obviating needless expenditure of time and money on experiments."

MR. RICHARD B. PILCHER, Registrar and Secretary of the Institute of Chemistry, writes:—"Had time allowed, I should have been glad to contribute to the discussion on Professor Fleming's paper, and to thank him for his reference to the work of the Institute of Chemistry. Whether it be described as the pursuit of invention, or as research, the results obtained by the Glass Research Committee of the Institute are, to my mind, an object-lesson, the main point of which is that success in scientific investigation depends on the selection of the right men for the work. At the outbreak of war, the stocks of laboratory glassware, hitherto entirely supplied from abroad, were speedily exhausted. The Germans had produced this glassware for over forty years, had made a speciality of it, and had all the necessary material for its manufacture in their own country. The Institute received an appeal signed by the directors of twelve of the largest steel firms in the country to take up the question of ensuring the supply of beakers and flasks; the Home Office asked for a formula for miners' lamp-glasses, and the Army medical contractors were known to be in urgent need of glass suitable for X-ray tubes. Within a few months the committee were able, through the work of Professor Herbert Jackson and Mr. Thomas R. Merton, of King's College, London, to provide formulas for meeting all these requirements. These results could not have been obtained without continuous research, mainly of an academic character, carried out by Professor Jackson with the object of arriving at the principles, chemical and physical, underlying the conditions for producing the glasses. Only the urgency of actual production has up till now delayed the publication of these researches. Mention should also be made of the intricate analytical work carried out by Mr. Gilbert J. Alderton, under the supervision of Mr. Bertram Blount. In arriving at the formulas, it was necessary to find substitutes for certain constituents, of which supplies were becoming practically exhausted; yet the glass is fully equal to the best German laboratory glass, and in some respects superior. Moulds had to be made and other devices to be obtained to enable manufacturers to produce all ordinary forms of glass apparatus. Even accurately graduated vessels with stopcocks of various forms will shortly be produced in large quantity by the British manufacturers, with whom the Glass Research Committee have been in touch throughout the work. The prices at which the ordinary forms of apparatus can be produced compare favourably with pre-war German prices, and there is every prospect that the industry will be held in this country after the war. It is certain that the manufacturers will make a good stand. Those to whom I refer, moreover, are not only good business men, but men with modern scientific training, and who appreciate science. All users of such ware should be urged to support these British manufacturers, for the industry is one in which we must be independent. It is not only important to remember that the chemist has now established his indispensability, but the instruments of his profession must be readily obtainable. The expenses of the work of the Glass Research Committee up to the point I have indicated were borne partly by the Institute and partly by Professor Jackson himself. Altogether twenty-one distinct formulas for glass required for scientific purposes are now available. The work is steadily progressing with the aid of a grant from the Committee of the Privy Council on Scientific and Industrial Research, from whom also a further grant has been allotted for research directed to the provision of certain forms of optical glass. I would venture to repeat that the Institute had the advantage of knowing where to find the right men for the work, and I think that in all practical problems directly affecting industry the aim should be to secure the right men, whether they are attached to a college or institution, or in consulting practice. Work of such pressing necessity should be entrusted at all costs to men of experience who have accumulated knowledge, and can at once bring it to bear on the subject to be investigated. In this work, moreover, a definite line of procedure was agreed upon from the start by the committee, under the chairmanship of the late Professor Meldola, and intimate touch was maintained with the manufacturers during and after the investigation up to the point of successful production. In other industries of direct concern to the practice of chemistry—porcelain laboratory ware, filter paper, reagents, etc.—British chemists have enabled British manufacturers to overcome all difficulties and to produce the necessary supplies. The Institute has been the means whereby many chemists have taken a part in industrial work, and I know that the British manufacturers have learned more and more to appreciate the value of placing well-trained and competent chemists in positions of control, not only in laboratories but on

the works. I believe the British nation can find chemists as fully able as any German chemist to solve any problem in industry. Moreover, I submit that whatever may be the failings of our public schools, they have succeeded in maintaining the British standard of individuality which has proved our greatest asset in peace and war, and particularly in times of stress. With all our facilities for training chemists and with their increasing influence in industry, I cannot share the gloomy outlook with which we are so often threatened."

MR. WALTER F. REID writes:—"In the discussion on Professor Fleming's suggestive paper, one fact was specially referred to, namely, the want of recognition, by the politicians who are at present in authority over us, of those who have done good work in science and industry, and especially of the inventor. The present state of war shows us how absolutely dependent we are upon new inventions if we are to maintain our place in the forefront of civilised nations, in war as in peace. And yet those who invent and produce the appliances and materials which will ultimately enable right to prevail over might are not thought worthy of any recognition, while honours are showered upon combatants for deeds which the inventor has made possible, and which, in fact, have a very slight influence upon our chances of success. The want of recognition of scientific men by the State is little less than a public scandal, and it is not to be wondered at if the best brains in the country are not attracted into channels that appear so limited. At the present moment the safety of Great Britain depends largely upon the work of the chemist, without whose loyal co-operation we could scarcely hope to cope with a nation which holds chemists in high esteem. And yet our Government even goes out of its way to prevent English chemists receiving any notice at all. Some years ago the French Chemical Society celebrated their fifty years' jubilee, and the chemical societies of this country sent three well-known chemists to convey their greetings to their French colleagues. The French Government, with a courtesy that our own might envy, offered the Cross of the Legion of Honour to these delegates of one of our most important branches of science and industry. Our own Foreign Office would not allow our countrymen to accept the compliment, and thereby gave our French friends to understand either that we did not value the proffered gift or that those to whom it was offered were not worthy of receiving it. Not long afterwards a military gentleman took a letter to a foreign Court and was given a high decoration—for a service which our Post Office could have carried out more expeditiously for 2½*d*. Some time before war was declared it became apparent to scientific men in this country that our army and navy were in a dangerous state of dependency upon Germany for the supply of optical glass, which is so necessary for the waging of modern warfare. The Royal Society, in conjunction with the National Physical Laboratory, appointed a competent committee of chemists to study the subject and introduce the industry into this country. Manufacturers were found willing to help; but a small, a very small, sum was required for the cost of the preliminary work, and this was refused by the Government. Everyone knows that at the outbreak of war it was necessary to do in a hurry what the Government had been urged to do long before. It is quite useless to discuss details of research and kindred subjects until we have executive officials who themselves possess sufficient elementary knowledge of science to be able to appreciate its importance in every branch of modern civilised life. The administration of the Patent Laws shows how little our State esteems the services of inventors; they are looked upon mainly as a source of income, whereas the real interests of the country would best be served by a cordial recognition of all those who have inventive genius. If an inventor does not patent his invention he has not the slightest chance of recognition in this country. For instance, the inventor of the process by which all the powder used in the present war is made is an Englishman, yet the only public recognition he has received has come from France and—Germany. Until we get rid of incompetence in high places, and give the scientific and technical worker the status which is his due, we shall not occupy the position among the nations which might be ours."

A VISIT TO THE WESTERN BATTLE FRONT.*

Permission was given to proceed to Ypres, which we did in the motors by way of Vlamertynghe, and the cars were deposited in the shelter of a wall at the canal head of the Yser Canal.

We then proceeded on foot to the headquarters, located in the middle of the town, where we were furnished with a guide to show us round Ypres itself.

Of the Cloth Hall one pinnacle alone remains standing, and we were told that the Germans not only have a daily shot at this pinnacle, but at least once a week shell the place freely. Not that there is anything in the shape of a building worth shelling, everything from the cathedral down to the smallest pork-butcher's shop being absolutely riddled with shell and shot, but apparently the object of the enemy's intermittent fire is to catch, if possible, the many troops who from time to time pass through the town to and from the trenches.

As a matter of fact, I saw the German "good-night" shell explode, as it seemed to me, right in the middle of Ypres, the result being a cloud of dust, and nothing more.

* Extracted from an account by one of a party of seven civilians who were invited by the War Office to visit the Western Front.

Having seen all that there was to be seen of the town, which was simply desolation of desolations, we proceeded on foot eastward, with the object, unexpected in the morning, of getting actually into the trenches. On leaving the town we came to a point where two roads parted, one south-east to Menin, the other east by north to Zonnebeke.

We walked in single file, being assured that a party like ours walking *en masse* would be spotted to a certainty, and after a most deviating journey, through the town cemetery to begin with (where tombstones flat and shell holes numerous made locomotion none too easy), we got for a few yards on to the road, then off again into the fields. Here we were halted to see if any airplane was having a look at us, then back to the road, walking probably for a hundred yards or so up the ditch, and so on until we came to another headquarters at Potyze, where we were within 1,500 yards of the first line of German trenches.

Thanks to an officer at these headquarters I was provided with a pair of thigh gum boots, being told that the ordinary knee boots would make progression in the trenches quite impossible. We were each of us also provided with anti-gas helmets, which, however, were not likely to be required, as the wind was unfavourable for the enemy. Then we proceeded, again in single file, to the second line of the British trenches, which are named after fashionable West End streets, and in the official war maps they are so described. For example, we entered by a communication trench called Haymarket, which led up to other trenches named Piccadilly, Jermyn Street, Duke Street, and so forth.

This particular position had been shelled freely by the enemy from 3 p.m. till dark on the previous day, and not only were the effects of the German fire plainly visible (barbed wire entanglements blown to smithereens, etc.), but the appalling state of the weather—rain in torrents throughout the day we were there—had turned the trenches into a stream of sliding mud.

We got as far as mud would allow, and were then within 1,100 yards of the German first line.

From where we were we saw what was described in the British Headquarters despatch on the following day as follows :—

" We bombarded the German position east of Ypres."

In these laconic words the official despatch describes a marvellous artillery duel between the German guns, which were behind a place called Railway Wood, about 4,000 yards away, rather to our right as we faced the German lines, and the British guns, which were, God knows where, somewhere miles behind.

We could see the German " Jack Johnsons " belching forth for all they were worth, and could hear them too, very plainly, even at that distance.

We could not hear the firing of the British guns, but we saw their shells burst, sending up mud spouts, which seemed to be hundreds of feet in height. We were told when we got back to headquarters that the British guns had done particularly good work that day.

The order then was to clear out of the trenches as quickly as possible, and we lost sight of one of the most amazing artillery conflicts which one could possibly imagine, though we continued to hear the roar of the big guns until we got right back to Ypres and long afterwards. We returned from Potyze by another road and by a very tortuous route back to the canal head at Ypres.

ZACATON GRASS FOR PAPER STOCK.

Attention is called to the possibilities of zacaton grass in the manufacture of paper in a new professional paper of the United States Department of Agriculture, Bulletin No. 309. Zacaton grass extends from California and Texas southward to the Argentine Andes. It grows most profusely, however, in the mountain regions east and west of the City of Mexico, where it is harvested for the sake of its roots. These are made into brushes of various sorts, and for this reason the zacaton plant is frequently known by the common English names of broomroot grass, wire grass, and rice-root grass. At the present time the tops of the plants are allowed to go to waste. It is from these that there is reason to believe that a satisfactory paper-making material may be developed.

An acre of grass should yield at least three tons of tops. The plant is a perennial one, the growth being almost entirely from self-sown seed. Unless checked by fire, cultivation, or the harvesting of the roots, the grass will soon cover a field solidly, and it is not uncommon to find many square miles densely covered with the growth. The range can be profitably gone over for roots every third year.

Laboratory tests of this grass conducted by the United States Department of Agriculture show that it can be chemically reduced to paper stock by the soda process more easily and with less expense than is necessary to reduce poplar wood. The same processes and methods which are employed for the manufacture of pulp from poplar wood are quite suitable for the treatment of zacaton, but in place of the wood-sawing, chipping, and screening machinery a grass duster is necessary.

The paper manufactured from the stock has proved as satisfactory in physical tests as a first-grade, machine-finished printing paper. It has,

moreover, a very satisfactory appearance and feeling. For bleaching, however, the experiments showed that more bleaching powder was required than with poplar stock.

The percentage of air-dry fibre obtained from the zacaton grass appears to be somewhat less than that from poplar wood, but practically equal to that of esparto. Forty-three per cent. of air-dry fibre was obtained in the Government experiments from air-dried grass, while the fibre yield from poplar wood ranges from 46 to 48 per cent.

No estimate of the cost of manufacture is made in the Bulletin mentioned above. A rapid increase, however, in the demand for paper, and the increasing likelihood that the raw material that is necessary for its manufacture will not be sufficient to meet this demand, make the subject worthy of further investigation by the trade. It has been estimated that the growth of wood in the United States is being removed at the rate of 36 cubic feet per acre each year, while the natural increase is at the rate of 12 cubic feet per acre. In other words, wood is being used three times as fast as it grows. The consequence is, of course, a continual increase in the price of raw material, and the desirability of finding some substitute is obvious.

BRAZILIAN PIASSAVA.

Among the forest resources of Brazil one of considerable value and importance is the fibre piassava, a product of certain palm trees, which is used in the manufacture of brooms, brushes, ropes, baskets and hats. The trees also produce a very hard nut, called in Portuguese "coquilho" (coquilla), from which excellent buttons are manufactured. The leaves are employed in making fans and, in the country districts, for roofing adobe houses. For making brooms and brushes, especially, no other material is more extensively employed in Brazil, and large quantities are required annually for domestic consumption as well as for exportation to Europe. The quantity and value of the exports of the fibre from Brazil in 1912 were as follows:—

To	Metric Tons.	£
United Kingdom	1,007·8	29,000
Germany	336·6	9,700
Portugal	196·3	5,700
Argentina	26·2	800
France	8·4	220
Belgium	6·2	170
	1,581·5	45,590

All but 12·3 tons was shipped from the port of Bahia. Some small shipments have been made lately to the United States. In 1914 only 55 lb. were sent, but in the first five months of the current year 12·6 tons, valued at £500, or between 4½*d.* and 5*d.* per lb. f.o.b. Bahia, have gone thither. It is said that the United States does not buy more because of competition from a variety of the same fibre grown in Africa.

Piassava is gathered from two species of palms, scientifically classified as *Attalea funifera* (mart) and *Leopoldinia piassaba* (wall). The Leopoldinia yields fibre in greater abundance, but its stand, so far as is known, is much more limited than that of the Attalea. Of the two varieties, the piassava of the Leopoldinia palm is the more delicate as to strength and finer in texture, but harder and very resilient, which accounts for its more common use in the manufacture of clothes-brushes, horse-brushes, to some extent flesh-brushes, and for cords and ropes, especially for nautical purposes, where strength, combined with small size and marked resistance to the action of sea water, is desired. This variety is most abundant in the Amazon region, in the tributary valleys of the Negro and Padouiry Rivers; but it is also plentiful in Northern Bahia, where, however, it is confined to the River Preto and other small feeders of the São Francisco. Though not gathered in quantities like the Bahian piassava (the common name for the Attalea variety), the last-named location is the region of its most extensive exploitation.

The Attalea palm is plentiful over large areas in the southern part of the State of Bahia, and exists in Northern Espirito Santo, and to some extent in Upper Bahia and Alagoas.

According to a report by the United States Consul at Bahia, piassava is gathered when ripe by drawing the fibres out from folds wound spirally around the tree at the base of the leaves, which seem to grow as a protection to the palm. It is extracted by unwinding and drawing out, the bunches obtained measuring 8 ft. to 15 ft. in length. The palms are exceedingly prolific in their fibre production, as from both varieties piassava can be gathered twice annually, a single tree yielding 4 lb. to 7 lb. at each drawing. The yield can be increased 30 to 40 per cent. by cutting down the tree and stripping it of all fibre, and, unfortunately, this wasteful method is so common that, unless legislative action is soon taken, the extinction of the piassava palms in the central forest zone is merely a matter of time.

After gathering, the fibre is allowed to dry for a time under cover, when the fibres are drawn singly from the tangled bunches and assorted as to length and grade. The dark-coloured fibres (of a dark brown shade) are the more valuable, as are the thicker and longer strands. The thick fibres are used for brooms and rough brushes, and the long ones for ropes and cords. The product is prepared for market in sheaves weighing 90 lb. to 110 lb., and sells in Bahia for 300 reis to 500 reis per kilog., or approximately 2*d.* to 3*d.* per lb.

ARTS AND CRAFTS.

War Memorials.—The inauguration of the Civic Arts Association and the meeting in its support at the Mansion House have produced a good deal of talk, and some correspondence in the public press, on the subject of war memorials. We are told, and very rightly told, that when the war is over we are to have a care that our memorials are better than the erections which perpetuate (not always pleasantly) the memory of Queen Victoria's Jubilee. We are also informed, again with considerable truth, that private memorials could and should be much better than they are. Various suggestions are, of course, offered as to how this state of affairs has arisen and is to be remedied. It is said, on the one hand, that the great sinner is the artist, who will carry out what he wants to do, not what the public (who, since they know that they do not like the atrocities of earlier times, presumably know both what they like and also what is good) really ask of him. Again, it is urged that the trouble arises because, owing to our undue submissiveness to the artist (exactly how this comes about is not made clear), a race of tradesmen has sprung up who foist upon the general public what they do not want. It is insisted that what we need is simpler work carried out by good craftsmen. No one denies that there is some truth in all these statements, especially perhaps the last two; but to get to the root of the matter we have to consider the iniquities not only of artists, architects and the like, but of the general public. It has yet to be proved that, say, the mayor and other civic officers of a small Midland town, or of one of the less enlightened London boroughs, would do better if they prepared a scheme for a memorial and gave it to a local craftsman to carry out than they would by entrusting the whole thing to an artist of some standing. It is at any rate doubtful whether the craftsman himself would think so at the end of the proceedings. There have been instances, of course, where a wayward artist has insisted on doing the wrong thing, but as a rule the work has suffered (more, perhaps, when entrusted to an artist than to a tradesman) from the fact that the designer has not been given a free hand, and the memorial when finished is the result of a compromise between him and his clients which is satisfactory to neither party. The trouble, as a whole, has been the dual control which has almost inevitably led to bad results. Whether the control should be in the hands of the artist or of the public is a question which might be answered in different ways. To reply adequately would demand some knowledge of the particular artist and the particular public involved. To substitute craftsman for artist may or may not help to get over the difficulty. Some of the best craftsmen are quite as determined to have their own way as any more ambitious artist. At the Mansion House meeting a way out of the *impasse*, by the formation of an association ready to give advice to both parties, was suggested. This sounds attractive enough, but the public has to have some guarantee of the capacity of the proposed association before they are likely to trust it to any very great extent. The meeting in the City was well attended. The speakers included Mr. George Clausen, R.A., Professor Selwyn Image and Professor Lethaby, whilst Mr. John Lavery, A.R.A., Mr. Frank Dicksee, R.A., and Sir C. Harcourt Smith were present. In other words, both painting and professorship were quite well represented; but with the exception of stained glass, the arts most commonly needed in connection with war memorials—sculpture, architecture, decorative painting, mosaic work—do not seem to have been seriously considered. This is the more to be regretted, as it is artists and craftsmen connected with these branches of art who have the greatest experience of the practical difficulties connected with the erection of memorials of all kinds. Any society which hopes to do good work in connection with memorials will have to be strong in men who are acknowledged masters, not of art theory or of painting alone, but of the arts, crafts and materials most directly concerned.

Further, while it may be hoped that some wise national control may be exercised over the erection of public monuments, the ordinary Englishman likes to settle (or at any rate to think he settles) his own private memorials for himself. What he wants is not so much artistic direction over particular points as a deeper artistic sense (which the proposed closing of the national collections will hardly assist him to acquire) and some elementary knowledge of the technical difficulties. In how many memorial tablets, for instance, is the lettering cramped and the proportion of the whole spoiled because the donor has had the happy inspiration at the last moment of adding to the length of the inscription, and it has been impossible to convince him that the change would make any real difference? He pays for so many extra letters, he argues, and it is the artist's business to make them fit in as best he can. It never crosses his mind, when he does not like the result, that the fault may be largely his own.

Wallpapers.—The wallpaper trade, like all industries which are largely dependent on colours, has suffered through the war. It will probably suffer still more from the restrictions on the importation of wood pulp. Meanwhile, since people must have something on their walls, business to some extent goes on. Moreover, a fair number of new designs are appearing this year, most of them drawn or commissioned before the war, but still new to the public. We did not import much in the way of wallpapers from Germany, though some of the plain

papers bought from Holland may have had a German origin. On the other hand, a good many French papers were sent to this country, and we exported to a considerable extent to the Continent and America. This last market is still open to us, and its existence should be a reason for seeing that the trade is not allowed to languish too badly. We want to export to America now, as well as to keep our market open for the future. Contrary to what might have been expected, this year's papers, though sometimes on a black ground, are generally bright and fresh in colour, and though purples are well to the fore, there is no lack of gay tints of all kinds. The increase in the use of transparent colours may be due to motives of economy; but it has tended to improve rather than to injure the effect of the patterns produced by this method. Stripes, once so popular, seem to have suffered at any rate a temporary eclipse, and spots are somewhat less in evidence, whilst their place has been taken by small all-over patterns which, without pretending to be anything great in the way of design, do, when they are properly planned, give a very pleasing effect. Some ingenious panelling arrangements with corners and side pieces, carefully schemed. are still being produced. It is worth noting that in nearly all the more highly priced papers there is still some suggestion of texture other than paper. This varies from a slight roughness, not intended to simulate anything in particular, to a deliberate imitation of silk or some other fabric. There is nothing remarkable in the continued production of the cheaper kinds of goods, but it is much more surprising that even at the present time a number of block-printed papers are being brought out. These have a much longer lease of life than the machine-printed papers, and are not necessarily, even in war time, an extravagance. Messrs. Jeffery & Co., whose work of this type is so well known, have never allowed their machine work to overwhelm this side of their production, and again this year they are bringing out quite important patterns, some on the lines of old silks and printed fabrics, some more modern in type, and yet others Japanese in feeling. There has been plenty of talk about carrying-on during the war, some of it sensible, some rather futile; but if we are to be ready for trade expansion when the present crisis is over we must have kept the best of our designers going while it lasts. If we are to do that, those interested in art, who can by any means afford it, should see to it that when they have to buy either wallpapers or fabrics they get new as well as good designs.

The Design and Industries Association.—The Design and Industries Association held its first annual meeting towards the end of last month. The society has now a membership of over two hundred, including a number of well-known artists and craftworkers, and a very fair proportion of members interested in manufacture and distribution; it has held one quite successful exhibition, and is beginning to make itself felt. If its ideal of drawing together artists and producers is not quite so new as some of its promoters seem to imagine, it is at least one which in recent years, owing very largely to the influence of the artist-craftsmen, has been allowed to drop out of sight. It is a good sign that this most important question is being considered seriously and with good will by a group of younger artists connected with various branches of applied art. Co-operation of this kind ought to have a good effect, not only on our design and manufacture directly, but also on the knowledge and taste of those who sell commodities into which the question of art enters in any considerable degree, and on the training given in our trade schools. If artists and manufacturers were really working together the trade schools, already doing excellent work, should become the training ground of workers capable of assisting by their knowledge and intelligence the movement towards unity.

OBITUARY.

Frederick Louis Myers.—Information has been received of the death of Mr. Frederick Louis Myers, of Kingston, Jamaica, which took place while he was on a visit to New York on October 5th last.

Mr. Myers was born at Kingston sixty-three years ago. On completing his education he decided to enter on a business career, and he started as a wholesale merchant and commission agent in his native city. Under his management the firm prospered, and finally became one of the largest and most powerful business organisations, not only in Jamaica, but in the British West Indies, and owned a large part of the wharfage of Kingston.

In addition to his business interests, Mr. Myers was a director of the *Gleaner*, a Kingston newspaper, and a member of the committee of the Kingston Chamber of Commerce. He was recently appointed Chief Magistrate of Kingston. He was also one of the trustees of the Royal Jamaica Yacht Club, in the affairs of which he took a great interest. He was a generous supporter of many charitable institutions, and the Jamaica War Contingent Fund owed not a little to him.

Mr. Myers only became a Fellow of the Royal Society of Arts last year.

GENERAL NOTES.

Banks and the War.—Mr. Walter Leaf, deputy chairman, when presiding at the annual ordinary general meeting of the London County and Westminster Bank, said that one of the

most satisfactory features about the great War Loan in July last was the manner in which their customers provided the money themselves; the cases in which the bank was asked to assist in subscriptions by loans were quite trifling in comparison, and there was no doubt that the amount subscribed represented the actual savings of the country, not any artificial inflation of credit. The immediate effect of that loan was, of course, a considerable drop in their deposits, which had no doubt been abnormally increased in anticipation of it. But that drop had since been largely made up again, and they had the satisfaction of seeing their aggregate deposits nearly eight millions in excess of those which the bank showed a year ago—a far larger sum than had ever appeared on any of their annual statements. The balance-sheet showed the large scale on which their bank, in common with all the banks of the United Kingdom, subscribed to that loan. All of the shareholders had now the opportunity of subscribing to the needs of the war in another form, that of the 5 per cent. Exchequer Bonds, which were now "on tap." He would urge upon all the desirability of doing so to the very utmost of their power. Sir Edward H. Holden, Bt., presiding at the general meeting of the shareholders of the London City and Midland Bank, Ltd., said that Germany, by the Law of August 4th, 1914, released the Reichsbank from its obligation to pay its notes in gold, and further authorised the creation of all kinds of notes without any gold cover at all. Traffic in gold was restricted by a penal Statute, passed by the Bundesrat on November 23rd, 1914, the effect of which was to make the buying or selling of gold coin at a premium punishable by fine or imprisonment. As their gold was tied up, German traders could only pay for imports by exports and securities, or by borrowing, or if there was an excess of imports and sufficient additional securities were not forthcoming, the exchanges must fall. It was quite certain, judging from the excessive fall of the German mark, that the imports into Germany from the Scandinavian countries, and from Holland, were largely in excess of her export of commodities and securities to those countries. Although the German mark had fallen about 33 per cent. in Holland, and about 23 per cent. in Scandinavia, they must not be premature in drawing conclusions. While it might betoken an exhaustion of German securities, yet the situation might be rectified to some extent if the gold were permitted to be exported. Of the two evils a fall in the exchange, or a loss of gold, the German Finance Minister preferred the former, and kept his gold. He had some good reason for keeping the gold, and it might be that when peace was restored he would begin to import commodities as quickly as possible, and as he would not be able to pay for such imports either with a depreciated currency or with sufficient exports, he would pay with his gold and try to restore the exchanges until such time as he could prepare his imported commodities for export.

Timber for Sleepers.—Particulars are contained in the recently published report of the Imperial Forest Research Institute, Dehra Dun, of experiments in connection with various timbers for use as railway sleepers. Four hundred and sixty sleepers of *terminalia tomentosa* were treated with mixed oil by the open tank process and laid down on the Great Indian Peninsula Railway, while the behaviour of sleepers previously laid down of *terminalia tomentosa, pinus longifolia, pinus excelsa, dipterocarpus, tuberculatus*, and *alatus* was carefully watched. Various sleepers have been laid down during the last few years, those treated by the Powell process have been in the track the longest. All are reported free from white ant attack. The *dipterocarps* and pines show signs of rail cut, indicating the need of bearing plates, while the latter showed signs of cracking and splitting, especially *pinus longifolia*. Mr. Pearson, the economist, has spent a portion of his leave in England in studying the various pressure and seasoning processes and their cost. Experimental work as regards oil absorption was taken up in Assam in connection with the indigenous woods with varying results. Gurjan sleepers were sent to England for treatment under the full cell process with good results, while 8 B. G. sleepers of ten promising timbers are being tested in England by the Ruping process. The whole subject of sleeper treatment is full of interest, but must still be regarded as being in the experimental stage, so much depending on the mechanical life of the various timbers. Minor investigations were carried out in connection with the physical, mechanical and seasoning properties of various timbers, while endeavours have been made to find markets for certain species. Investigations were also made, as far as time permitted, into a large number of products, such as tannins, gums, resins, oleo resins (the Boswellia gum promises to yield important results), fibres (especially that of *helicteres isora*), oil, seeds, essential oils, timbers suitable for paving blocks, pencils, casks, bobbins (for which there is a large demand) and lance shafts, etc.

Encouragement of Olive Cultivation in Tripoli.—To encourage the cultivation of the olive tree in Tripoli, a decree has lately been issued by the governor-general of that colony, offering a premium of 40 centimes for each plant raised from seed or cutting. A free distribution of cuttings of the olive tree will be made by the "*Ufficio agrario*" at Tripoli to intending growers and colonists. The young plants must be healthy and well grown.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m. :—

February 16. — S. Charles Phillips, M.S.C.I., "Paper Supplies as affected by the War." Lord Burnham will preside.

February 23.—Miss H. B. Hanson, M.D., B.S., D.P.H., "Serbia as seen by a Red Cross Worker."

March 1.—Charles Delchevalerie, "Belgian Literature."

March 8.—Charles R. Darling, A.R.C.Sc.I., F.I.C., "Optical Appliances in Warfare."

March 15.—Edward Percy Stebbing, F.L.S., F.R.G.S., Head of the Department of Forestry, University of Edinburgh, "Forestry and the War."

March 22.—Rev. P. H. Ditchfield, "The England of Shakespeare."

Victor Horta, Directeur de l'Académie Royale des Beaux-Arts de la Ville de Bruxelles, "Belgian Architecture."

Professor T. G. Masaryk, "The Slavonic Peoples."

G. P. Baker, "Hindu Hand-painted Calicoes of the Seventeenth and Eighteenth Centuries, and their Influence on the Tinctorial Arts of Europe."

Arthur S. Jennings, "Painting by Dipping, Spraying, and other Mechanical Means."

Indian Section.

February 17.—C. A. Kincaid, C.V.O., Indian Civil Service (author of "Deccan Nursery Tales," "The Indian Heroes," "The Tale of a Tulsi Plant," etc.), "The Saints of Pandharpur: the Dawn of the Maratha Power." Lieut.-Colonel Sir David W. K. Barr, K.C.S.I., will preside.

March 16.—Professor Wyndham R. Dunstan, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India."

April 27.—James MacKenna, M.A., I.C.S. (Deputy Commissioner, Myaungmya, Burma, and designated Agricultural Adviser to the Government of India), "Scientific Agriculture in India."

May 18. — Sardar Daljit Singh, C.S.I., "The Sikhs."

Colonial Section.

February 28 (Monday, at 4.30 p.m.).—Percy Hurd, "Next Steps in Empire Partnership."

April 11 (Tuesday, at 4.30 p.m.).—Sir Daniel Morris, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland."

May 2 (Tuesday, at 4.30 p.m.).

Dates to be hereafter announced :—

R. W. Seton-Watson, D.Litt., "The Balkan Problem."

W. A. Craigie, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

Cantor Lectures.

Monday afternoons, at 4.30 p.m. :—

J. Erskine-Murray, D.Sc., F.R.S.E., M.I.E.E., "Vibrations, Waves, and Resonance." Four Lectures.

May 1, 8, 15, 22.

Fothergill Lectures.

Monday afternoons, at 4.30 p.m. :—

Rev. Dr. Herbert West, D.D., A.R.I.B.A. (author of "Gothic Architecture in England and France"), "National and Historic Buildings in the War Zone: their Beauty and their Ruin." Three Lectures.

Syllabus.

Lecture II.—February 14.—*Gothic Architecture, French and English.* The French Cathedral, a Great Hall, the centre of the city's life. The English Cathedral a Monastic Missionary settlement, independent of the city. The problem of Mediæval Architecture, to reproduce Roman vaulting—Solved by permanent stone centrings (diagonal ribs) under the intersections of a groined vault (Vezelay, Durham, St. Denis, Sens). Buttresses necessary (Chartres, Amiens, Beauvais). The walls become screens of glass. Inside—Columns replaced by vaulting ribs running down to the ground (Notre Dame—N. D. de l'Épine, Abbeville). Contrast of French and English plans (Notre Dame and Salisbury). In the English Cathedral, horizontal, not vertical perspective sought. Beauty of clustered columns. Purbeck causes deep mouldings. Multiplication of vaulting ribs. Lierne and fan vaulting—Flamboyant and perpendicular—English and French façades—The French Cathedral is the expression of the National ideal; the English, of the National history.

Lecture III.—February 21.—*French Mediæval Sculpture.* Christian art that of a new-born society rising amidst a dying civilisation—Provençal sculpture, Arles, etc., decadent—Burgundian, full of life and imagination; but Classical

influence traceable all through (Vezelay, Autun, Auxerre)—XIIth Century (Avallon, Bourges, N. and S. doors, Chartres, W. front). Elongation of statues, architectural not ignorant—Individual types, elaborate detail. The sculpture scheme of a XIIIth Century cathedral (Laon, Notre Dame, Amiens, Reims). The Judgment door (Autun, Notre Dame, Amiens, Rampillon, Reims, St. Maclou)—The Virgin's door—Local Saints and legends (St. John Baptist, Rouen; St. Stephen, St. Théophile, Paris; St. Thomas, Semur; St. Nicaise, Reims)—The Arts, Virtues and Vices—The Months and Daily Life (Paris, Amiens, Rouen)—Statuary (St. Stephen, Sens—The Virgin, Paris—Chartres, N. and S. porches)—Reims, W. portals—Figures of Christ (Chartres, Amiens, Reims, Troyes, Solesmes).

The lectures will be illustrated by lantern-slides.

EDWARD A. REEVES, F.R.A.S., Map Curator, Royal Geographical Society, "Surveying." Three Lectures.

March 27, April 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 14...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Fothergill Lecture.) Rev. G. H. West, "National and Historic Buildings in the War Zone: their Beauty and their Ruin." (Lecture II.)

Economics and Political Science, London School of, Clare-market, W.C., 5 p.m. Hon. W. P. Reeves, "The Balkan States." (Lecture II.)

Cold Storage and Ice Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 7.30 p.m.

Brewing, Institute of (London Section), Imperial Hotel, Russell-square, W.C., 8 p.m. Mr. H. C. Sweatman, "The Work in a Brewery Cooperage."

TUESDAY, FEBRUARY 15...Sociological Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.15 p.m. Mrs. St. Clair Stobart, "The Meaning of War from a Woman's Standpoint."

Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. W. H. Manfield, "Oil Shales, especially those of Dorsetshire."

Statistical Society, 9, Adelphi-terrace, W.C., 5.15 p.m. Major L. Darwin, "Statistical Enquiries needed after the War in connection with Eugenics."

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. S. Sherrington, "Nerve Tone and Posture." (Lecture V.)

Philosophical Institution, Edinburgh, 8 p.m. Mr. O. Bainbridge, "Turkey and the Turks."

Hampstead Antiquarian and Historical Society, Central Library, Finchley-road, N.W., 8.15 p.m. 1. Annual Meeting. 2. Address by the President (Dr. H. B. Wheatley), "Pepys' Work at the Navy Office and the Admiralty."

WEDNESDAY, FEBRUARY 16...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. S. C. Phillips, "Paper Supplies as affected by the War."

Meteorological Society, 70, Victoria-street, S.W., 7.30 p.m. 1. Mr. C. E. P. Brooks, "On the Rainfall of Nigeria and the Gold Coast." 2. Dr. J. R. Sutton, "South African Coast Temperatures."

University of London, King's College, Strand, W.C., 5.15 p.m. Mr. S. Low, "The War and the Problems of Empire." (Lecture III.)

Microscopical Society, 20, Hanover-square, W., 8 p.m. 1. Messrs. Heron-Allen, Earland and Rousselet, "The Progress and Development of Vision and Definition under the Microscope." 2. Mr. J. E. Barnard, "An Experiment with the Ultra-Microscope."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5.15 p.m. Professor Gerothwohl, "The Octopus of German Culture."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 5.30 p.m. Mr. C. F. Marsh, "Reinforced Concrete as applied to Waterworks Construction."

THURSDAY, FEBRUARY 17...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Mr. C. A. Kincaid, "The Saints of Pandharpur: the Dawn of the Maratha Power."

African Society, Hotel Cecil, Strand, W.C., 8 p.m. Major J. J. O'Sullevan, "The Campaign on the German East Africa-Rhodesian Border."

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Chemical Society, Burlington House, W., 8.30 p.m. 1. Mr. P. W. Robertson, "The simultaneous estimation of carbon and bromine by the chromic acid method." 2. Messrs. J. B. Cohen, D. Woodroffe, and L. Anderson, "The relation of position isomerism to optical activity. Part X.—The menthyl alkyl esters of 3- and 4-nitrophthalic acid, etc." 3. Mr. E. E. Turner, "A new reaction of semicarbazide hydrochloride." 4. Mr. A. G. Perkin, "Note on a product of natural indigo manufacture." 5. Mr. L. Aitchison, "The action of sulphuric acid upon alloy steels." 6. Mr. S. G. Sastry, "Additive compounds of s. trinitrobenzene with heterocyclic compounds containing nitrogen in the ring." 7. Mr. A. Bramley, (*a*) "The study of binary mixtures. Part II.—Densities and viscosities of mixtures containing substituted phenols; (*b*) Part III.—Freezing-point curves; (*c*) Part IV.—Heats of reaction and specific heats."

Royal Institution, Albemarle-street, W., 3 p.m. Sir Frank Dyson, "Measurement of the Brightness of Stars. Lecture II.—The Variable Stars."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. C. M. Thomas, "A Printing Process for Physical Development."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. (Kelvin Lecture.) Dr. C. Chree, "Terrestrial Magnetism."

Historical Society, 7, South-square, Gray's Inn, W.C., 5 p.m. Anniversary Meeting.

Numismatic Society, 22, Albemarle-street, W., 6 p.m. Mr. J. Mavrogordato, "The Coins of Chios. Part II.—478-334 B.C."

Geographical Society, Kensington-gore, W., 5 p.m. Dr. J. F. Unstead, "A Synthetic Method of Determining Geographical Regions."

FRIDAY, FEBRUARY 18...Royal Institution, Albemarle-street, W., 5.30 p.m. Professor E. G. Coker, "Polarised Light and its applications to Engineering."

Economics and Political Science, London School of, 5 p.m. Hon. B. R. Wise, "Industrial Organisation."

University of London, Bedford College, York Gate, Regent's Park, N.W., 5 p.m. Professor J. S. Mackenzie, "The Relation of Right and Might."

Mechanical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, Westminster, S.W., 6 p.m. Mr. H. Fowler, "Chisels."

SATURDAY, FEBRUARY 19...Royal Institution, Albemarle-street, W., 3 p.m. Hon. J. W. Fortescue, "Eminent Generals of the last Great War. Lecture I.—Sir Ralph Abercromby and Sir Charles Stuart."

Journal of the Royal Society of Arts.

No. 3,300. VOL. LXIV.

FRIDAY, FEBRUARY 18, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 21st, 4.30 p.m. (Fothergill Lecture.) REV. DR. HERBERT WEST, D.D., A.R.I.B.A. (author of "Gothic Architecture in England and France"), "National and Historic Buildings in the War Zone: their Beauty and their Ruin." (Lecture III.)

WEDNESDAY, FEBRUARY 23rd, 4.30 p.m. (Ordinary Meeting.) MISS H. B. HANSON, M.D., B.S., D.P.H., "Serbia as seen by a Red Cross Worker." SIR FRANCIS CHARLES GORE, K.C.B., Hon. Treasurer of the Serbian Relief Fund, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

FOTHERGILL LECTURE.

On Monday afternoon, February 14th, the REV. DR. HERBERT WEST, D.D., A.R.I.B.A., delivered the second lecture of his course on "National and Historic Buildings in the War Zone: their Beauty and their Ruin."

The lectures will be published in the *Journal* during the summer recess.

PROCEEDINGS OF THE SOCIETY.

TENTH ORDINARY MEETING.

Wednesday, February 16th, 1916; THE RIGHT HON. LORD BURNHAM in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Barneson, Captain John, 310, Sansome-street, San Francisco, California, U.S.A.

Parrish, Samuel L., Southampton, Long Island, New York, U.S.A.

Sadd, W. A., Chattanooga Savings Bank, Chattanooga, Tennessee, U.S.A.

Tabor, Joseph Matthew, Peninsular House, Monument-street, E.C.

The paper read was—

PAPER SUPPLIES AS AFFECTED BY THE WAR.

By S. CHARLES PHILLIPS, M.S.C.I.

INTRODUCTION.

I would like, with your permission, at the outset to say that this is a subject it is impossible to approach without a sense of difficulty, because it is outside the range of possibility at the moment to form even an approximate idea how the war may affect paper supplies, and in considering the material for this brief paper I have been compelled to realise how almost from day to day the situation alters and the element of uncertainty in regard to paper supplies, and incidentally, I may add, paper prices, are affected. I assume it is the wish of the Society, or at least I interpret their wish as a desire, that I shall present a few facts which concern particularly the British Empire. In saying this it must be borne in mind that the general interests of the paper trade, and of the raw materials upon which the paper trade depends, are international in extent, and it is desirable in considering how Great Britain and Ireland may be affected to glance briefly at what is happening in various parts of the world where we buy and sell paper. The importance and influence of this indispensable commodity are so great that in this twentieth century the world would without it, so to speak, come to a standstill. It is already a matter of history that this country was embroiled in the present terrific war through what Germany termed a "scrap of paper."

Two outstanding facts force themselves firstly upon our consideration, viz., that when war broke out in August, 1914, the considerable supplies we were receiving from Germany and Austria were cut off, and, of course, have not since been resumed. I do not propose at this stage to mention in detail the particular classes of paper in which Germany or Austria

admittedly specialise, but they exercised a great influence in our markets, and are very well known in the paper trade. It will be realised from the figures I am about to present that the mere fact of these supplies being stopped by force of circumstances affected paper consumers in this country at once, and the effect has been more acute as the war has progressed. Outside the countries with whom we are actually at war quite a number of other paper-producing nations have been directly affected. France, Belgium, and Italy, being deeply involved in the struggle, have been and are unable to supply this and other countries with the particular classes of paper to which they had devoted their attention with considerable success. Although the supplies from our Allies referred to have not been entirely cut off, they have been greatly hampered; in fact, within a recent period France has been in our market as an important buyer, particularly for "news" or, in other words, the class of paper used for the printing of newspapers.

The countries directly affected by the war are Great Britain, Ireland, Germany, Austria, France, Belgium, Italy, Russia (Finland), Japan, and, incidentally, America and Canada, as the extraordinary increase in freights, chemicals, coal, and other indispensable commodities has made the effect, generally speaking, world-wide. And, of course, Norway, Sweden, and Holland, with whom we do an enormous business, have also found that the effects of the war are of considerable importance in many directions. Finland, too, on whom this country depended largely for nature browns and a fair quantity of "news" and boards, has been almost cut out of our market, and only those directly associated with the paper trade can realise how the stoppage of these supplies and the general chaos resulting from the war has affected and will affect consumers and traders.

Many people are wise after the event, and some of the comments on what has happened in the paper trade have been made rather lightly and apparently without full consideration. In my opinion, the general conditions governing the situation could not possibly have been accurately predicted or the effects gauged when war broke out. The conditions so far as they concern the paper trade and many other trades were, of course, unprecedented, and it is not surprising that some of our best-informed business men formed erroneous ideas as to what would probably happen. In this consideration it is well to bear in mind the factors directly governing paper prices. First we will deal with the supplies of raw materials—wood pulps, esparto, rags, coal, chemicals, dyes, etc., and it must be borne in mind in this consideration that substantially all wood pulps are imported into this country. This applies also to esparto, and everyone, no doubt, is fully aware how largely we were dependent on Germany for the dyes necessary for the production of coloured papers.

Probably we may at no distant date learn something regarding the involved and embarrassing situations arising and likely to occur with regard to the interpretation of pre-war contracts and contracts made since the war broke out. Some of these involve great difficulties and hardships, but so far as I can learn the general inclination of traders in Great Britain appears to be to interpret their obligations in a reasonable spirit, although, in saying this, I am well aware that some interested people will not agree with me.

If time permitted I could deal at length with the unforeseen difficulties, not only in regard to the production of paper, but also in carrying out certain contracts, and in regard particularly to deliveries, and those intimately associated with the paper trade are pretty well aware how these difficulties and the recent methods of conditional quotations affect merchants, agents, and buyers. Probably when the war is over we shall realise the great and noble part our British Fleet has played in enabling wood pulp, esparto, etc., and paper to come to our shores so freely since the so-called blockade of this country was announced. Literally, although there have been some misfortunes and a number of ships have been sunk, there has been no insuperable difficulty in regard to the landing in Great Britain and Ireland of cargoes from Scandinavia or from Canada and America. In this matter our misguided neighbours across the North Sea—the Germans — have, I must admit, acted impartially, for they have sunk more neutral ships, Norwegian, Swedish, and Danish, carrying such cargoes than British ships—a kind of impartiality which has not been appreciated by the neutrals referred to. It is true that freights have made shipping virtually impossible from certain ports, but the dreaded blockade, as such, has not materialised; and I think you will agree with me when I say it will not do so. I propose to give you a few figures, and these will serve to correct certain erroneous ideas which, I believe, are widespread.

It will be noted that America comes first in importance as a paper-producing nation,

although the bulk of the paper produced in the United States is consumed at home. It has been stated more than once that Germany, as regards bulk, took a strong lead. This you will note is not the case, although Germany and Austria had come along at a great rate as exporters. It remains to be seen how these figures will be altered by the war and after the war. America, it will be observed, has not played a great part in relieving the situation here, and this has probably been due in the first instance to a want of knowledge of our requirements and the conditions under which business is done over here; also, of course, to the high freights which make the shipment of cheap grades of papers by European buyers very difficult — though with the high prices prevailing to-day the question of freight should not form a serious obstacle. The same remark applies to some extent to Canada, and personally I hold a very strong view as to the part Canada will play at no distant date in regard to the production of both pulp and paper; but it may be well to bear in mind that the United States of America is, geographically, the natural market for Canada, although in normal times Canada can ship to Great Britain at a cheaper rate than the material costs for transport to some of the important centres in the United States. While on this subject, I might state that during my many visits to Canada for the past thirty years, I have endeavoured to implant enthusiasm and interest among my pulp-making friends over there in the direction of developing their mills on a larger scale with the view of competing over here for a much larger portion of our pulp business which is awaiting them. In spite of the war, the Canadian wood-pulp business is being developed in a very gratifying manner, and after the war it will receive a much greater impetus. We cannot afford to put all our eggs into one basket.

Buyers were quite in the dark as to what might happen when war broke out, and panic prices and a rush to place orders practically at doubled figures, particularly for "news" and printing papers, occurred immediately war was declared. Then a reaction took place and an indifferent demand, coupled with over-production, resulted in very poor prices. Naturally the fact that most of our paper-makers were well covered for pulp requirements had much to do with this phase of the subject. As a matter of fact, contracts for paper could be placed at pre-war prices. The market experienced a period of great uncertainty, some mills working on very good contracts, some on very poor contracts, some mills being actually short of orders for a period, whilst further dislocation was caused by certain mills, usually turning out higher classes of paper, having accepted contracts for newspaper publishers' requirements.

It is well known that some of our most astute buyers made serious mistakes in regard to the market. Some contracts were cancelled for considerations, and one of our largest firms paid a substantial cheque to a paper firm to secure the cancellation of one big order.

I could say much if it were necessary as to why prices have increased, are increasing, and may probably continue to increase, and those who understand the position will realise that paper-mill managers in this country cannot reasonably be expected to commit themselves to contracts for long periods ahead.

It is gratifying to know, as I do know, that the British Paper Makers' Association is fully alive to the possibilities now opened to the British paper trade by securing a large amount of business hitherto in the hands of foreign firms, and this applies not only to the paper consumed here, but also to the export trade. It is also fairly well known that many paper-mills in Great Britain are now spiritedly making, with considerable success, classes of paper which have hitherto for some reason been classified as foreign papers. These include greaseproofs, flints, fancy box linings, imitation greaseproofs, krafts, gold and silver foils, very thin papers for special purposes, vegetable parchment, etc.

I have been frequently asked what may be the position of the British paper trade after the war. On this subject I am an optimist, and I believe that the war has had the effect of consolidating our paper-makers, removing to a large extent the mutual suspicions which seem to be part of the paper-makers' natural constitution, and also bringing the principals into closer touch, with very excellent results.

I am also well aware that in the last decade the great improvement in paper-making methods and equipment, also in technical and commercial education, have placed British paper-making firms in the front rank, considered from the international standpoint; and incidentally it is also gratifying to know, as a matter of fact, that in regard to paper-making machinery it is now fully recognised that our British engineers are in a better position to-day, providing they are not occupied on munitions, or other Government work, and labour is available, than ever before.

No doubt our paper-makers will take a leaf out of the Germans' book, throw over the old rule-of-thumb system and adopt more scientific methods in an industry which is acknowledged to be more susceptible of scientific treatment than most other industries of this country.

Had British paper-makers been more alert and less conservative in their ideas and actions years ago they would not have allowed the Germans to have monopolised many lines of paper and thus made us dependent on them for supplies. As in the case of other British industries, we have only to thank our insular ideas and proverbial prejudices for neglecting to foster business in our mills and factories which the Germans have exploited so profitably.

Paper Production of the World.

The most recent estimate of the paper and board production of the world which I have been able to turn to is that of Mr. G. R. Snellman, of Helsingfors, a well-known authority, who in 1912 gave it as 7,856,591 tons of paper and 1,576,289 tons of boards, which gives in round figures a total of about 9½ millions of tons. These figures, no doubt, are now considerably below the mark, but they will afford a fairly reliable basis for estimating the proportion of paper products of each of the belligerent countries. In passing, it may be interesting to observe that up to the outbreak of war about 37 per cent. of the paper manufactured throughout the world was produced in the United States of America, which are also to be credited with the production of about 60 per cent. of all the boards manufactured. Dealing with the belligerent countries, it appears that in respect of paper the percentages* of production are as follows: Germany, 17·1; England, 11·1; France, 7·6; Austria-Hungary, 4·4; Canada, 3·2; Italy, 2·9; Russia, 2·8; and Finland, 1·2. With regard to the manufacture of boards, Germany's production on the census I give is equivalent to 11·8 per cent.; that of France to 5·8; Canada, 3·2; Austria-Hungary, 2·2; Russia, 1·5; and England, 1 per cent. The fact that we are not a pulp-producing country accounts for the low percentage of boards produced by our mills.

Conditions in the British paper trade at the outbreak of war were of normal though moderate prosperity, one of the most significant features being the huge development in the output of news and printing papers in the Thames district. This had been planned on the most modern and enterprising lines for securing economical production, with the result that it is doubtful whether there is any place in the world able to turn out these two classes of paper at such a low cost. I have the authority of a well-known paper-maker in Lancashire for stating that new southern mills come nearer to a solution of the foreign importation problem than anything ever before attempted in Great Britain. I shall have something to say shortly with regard to our imports of paper and boards, but here it is convenient to remark that about one-half of our total consumption of paper is of foreign origin, and though that consumption has continued to increase, the growth has been very largely met and monopolised by German and Scandinavian manufacturers. Home products of paper normally average between 700,000 and 800,000 tons, while the total annual imports of paper during the last three years amounted, in 1913 to 394,080 tons; in 1914 to 359,000 tons; and in 1915 to 322,000 tons.

These imports consist of almost every kind of paper except finest writings, and in this connection it may be said that Germany and Austria sent us some papers of great artistic merit, evincing the highest skill in manufacture, in addition to papers of peculiar utility which are quite specialities. Among these may be mentioned filter papers, photographic papers, fancy greaseproofs, vegetable parchments, leather papers, ferro-prussiate papers, telegraphic tape papers, etc., most of which are expensive products, and mostly the result of patient and highly-skilled labour and enterprise.

Naturally the war has, to all intents and purposes, put an end to our import of these specialities, the absence of which has been keenly felt. It is therefore gratifying to be able to state that great efforts are being made, and will, no doubt, continue to be made, to produce them in our British mills. My own opinion is, and it is endorsed by more than one British paper manufacturer, that there is a reasonable prospect of success under the stimulus of very high prices resulting from scarcity, and that there seems every reason to believe that the encouragement of the efforts which are being made in this direction may ultimately render us independent of the foreign supplies. In that event British paper-makers will have achieved a fine conquest over an entirely new field, in which up to now German supremacy has been practically unchallenged. With this object in view I would plead for a sympathetic attitude amongst buyers towards our paper manufacturers in the early

* These, and other percentages, are approximate only.

stages of what is a new, and may become a very important, development.

In view of the fact that so large a proportion of our supplies of paper comes from enemy countries and countries at present under their control, it is not surprising that we in this country have experienced a gradually increasing scarcity in our markets. This arises not only from the stoppage of supplies from Germany and Austria, but, to a large extent, from the diversion of Scandinavian paper products to the South American and Far Eastern markets to replace papers previously supplied by Germany. As a result, for many sorts of paper something approaching famine conditions exist, and it will in my view undoubtedly become necessary to make some organised effort to check the immense waste of paper which goes on daily. There is no doubt that very great economies in the use of paper are possible, and to remedy this state of things Government, municipal, and other public bodies, as well as industrial and commercial concerns and private individuals, can do much by the exercise of rigid economy in the use of paper of all kinds.

Imports of Paper.

The main sources from which this country in pre-war times supplemented its own production of printing and writing papers of various kinds were Sweden, Norway, Newfoundland, Germany, Belgium, Finland, and the United States, France also contributing a small quantity. Packing and wrapping paper, especially sulphite papers, was chiefly derived from Sweden and Norway, of which countries Germany was a close competitor, while Belgium and Russia, with "other countries," sent us appreciable quantities. Imports of "news" paper were principally from Norway, Newfoundland, and Sweden, in the order indicated. These furnished between them in 1913 about 85 per cent. of our purchases of this class of paper, which totalled 131,443 tons. Germany's contribution was only 8,640 tons, or slightly over 1·3 per cent. Of printing and writing paper not on reels we imported in 1913, 50,109 tons, 34·7 per cent. coming from Norway, 30 per cent. from Germany, 14 per cent. from Sweden, and 9·5 per cent. from Belgium, the remainder coming from the United States and other countries. The imports of printing and writing papers (on reels and not on reels) from the various countries in 1913 were in the following proportions: Norway, 33·9 per cent.; Newfoundland (entirely "on reels"), 17·4 per cent.; Sweden, 16·2 per cent.; Germany, 13·5 per cent.; Belgium, 2·6 per cent.; United States, 2·3 per cent.; "other countries," including, presumably, Austria, Italy, and Canada, 8 per cent.

The foregoing are the figures for what may, for present purposes, be considered a normal pre-war year (1913), and it will be useful and interesting to compare with them the percentages of imports of the same kinds of paper in 1915, a full year of war. As was to be expected, there was a considerable shrinkage in imports of paper and boards last year compared with that of 1913, the total amounting to 586,322 tons, as against 644,087 tons. Paper on reels showed a decrease of nearly 29,750 tons, the total imported being 106,720 tons. Of these Newfoundland contributed 44·7 per cent., Norway 30·3 per cent., Sweden 11·2 per cent., the United States 4·6 per cent., and "other countries" 9 per cent. For the first time in the history of the paper trade Newfoundland took premier position as an exporter to this country of paper on reels, the total amount being 47,789 tons, 15,410 tons in excess of those from Norway.

"Paper not on reels" was imported to the extent of 32,450 tons, being but 65 per cent. of the imports of similar paper in 1913, the percentage of Norway being 44·2, Sweden 26·3, Belgium 5·1, the United States 4·7, and "other countries" 19·1. It will, therefore, be seen that of the combined imports of printing and writing papers 34·7 per cent. came from Newfoundland, 33·5 per cent. from Norway, 14·5 from Sweden, 4·7 from the United States, and 11·3 from "other countries," which included Holland, Italy, etc. A cursory comparison of the statistics indicates that while Germany has, of course, been a sealed book, so far as imports are concerned, this country has to a large extent maintained its supplies from Norway and Sweden to within slightly more than 26 per cent. of those of 1913. The United States contributed last year over 51 per cent. more than two years ago, Newfoundland 11 per cent. more, and "other countries" 7·5 per cent. Belgium, though under the iron heel of her oppressors, managed to send us rather more than 34 per cent. of her normal quantity as represented by the figures for 1913. But it is evident that we must not expect any more from Belgium until the termination of the war, seeing that Germany has now prohibited exports of paper from that country.

With regard to paperhangings, imports in 1913 amounted in the aggregate to 2,865 tons, Germany's contribution being approximately

66·4 per cent., Belgium's 26·2 per cent., and "other countries" 7 per cent. In 1915 imports totalled but 169½ tons, 44 cwts. coming from Germany, none from Belgium, and 167 tons from other countries. Compared with 1913, when of the total imports of "other printed or coated papers" 52·7 per cent. came from Germany and 33·3 per cent. from Belgium, the figures for 1915 show a decline of 56·4 per cent., the total being 2,317 tons, of which no less than 67·3 per cent. came from Belgium, the remainder being divided between France, the United States, and other countries.

Imports of "packing and wrapping papers" in 1913 reached 204,514 tons, of which 33·4 per cent. came from Sweden, about 26 per cent. from Norway, 21·5 per cent. from Germany, 6·8 per cent. from Belgium, 6·4 per cent. from Russia (Finland), and 5·1 per cent. from "other countries." Last year 180,460 tons were imported. A negligible quantity, 418 cwts., seems to have reached this country from Germany, while Belgium's share fell to 1·6 per cent., and Russia's to 0·44 per cent. To a large extent these defections were balanced by increased supplies from Sweden, Norway, and "other countries," the respective percentages being 45·4, 42·8, and 9·5.

Strawboard, mainly the product of Holland and partly of the United States, though hitherto Germany and Austria have also exported these goods to us, totalled 176,500 tons in 1913 and 191,100 tons in 1915, while imports of millboards and wood-pulp boards, from the Scandinavian countries mainly, which in 1913 reached 65,950 tons, amounted last year to nearly 60,650 tons. Unenumerated classes and articles of paper were imported to the extent of 12,400 tons, an increase of 40 per cent. upon the returns for 1913. Almost the whole of this business has undoubtedly been done under the nose of the enemy's great war fleet, checkmated so wonderfully and effectually by the constant watchfulness of our own incomparable fleet, every overseas' route being strongly guarded by those whose duty it is to direct the British Navy to keep open for ourselves and our friends the waterways of the world for the benefit of its commerce, inward and outward.

Exports.

The effect of the war upon Britain's export trade in paper, etc., cannot be said to have been at all disastrous. The total exports of paper, boards, etc., in 1914 were 3,124,306 cwts., and last year 2,759,299 cwts., as against 3,498,914 cwts. in 1913. This must be considered an exceedingly favourable comparison under the circumstances, indicating as it does that, notwithstanding the loss of the German and Austrian markets, the dislocation of trade generally, shipping difficulties, and the restriction of output following upon so large a number of workers having joined the Colours, British paper manufacturers have been able to maintain their export trade to within about 21 per cent. of normal. Exports of British writing papers, as a matter of fact, were of practically average volume, being less than 4 per cent. below the total of 1913, while those of printing papers were 22·4 per cent. below the level of two years ago. Of these two kinds of paper 65·7 per cent. went to various parts of the British Empire, our largest customers being Australia, British India, New Zealand, and South Africa, 7·6 per cent. going to France, and the remainder to the United States and other foreign countries.

Our exports of packing and wrapping papers last year amounted to 36,281 tons, compared with 45,272 tons in 1913, those of printed paper-hangings to 4,192 tons as against 6,393 tons two years ago, and other printed or coated papers to 1,033 tons compared with 1,400 tons in 1913. Exports of pasteboard, millboard, and cardboard declined in 1915 by 40 per cent., manufactures of pasteboard, millboard and cardboard by 19 per cent., envelopes by 20 per cent., and bags by 8 per cent., while those exports of paper coming under the designation "unenumerated" decreased by nearly 14 per cent., due entirely to the falling-off of exports to France, the United States, and other foreign countries, those to the British Dominions showing an advance of 8·5 per cent. It must be borne in mind that the fact of our paper-makers being called upon to meet a heavier home demand for their production has naturally caused a contraction of their export business.

Pre-War Trade with Germany and Austria.

The extent of this country's pre-war trade in paper with Germany and Austria-Hungary has been dealt with in detail by the Commercial Intelligence Branch of the Board of Trade, which, towards the end of 1914, issued a statement dealing with the exports of paper, pasteboard and cardboard from those countries to the United Kingdom in 1912 and 1913. This showed our imports of paper, cardboard, etc., from Germany in 1912 were of the value of £1,286,000, while those from Austria-Hungary in 1913 were valued at £43,300. British exports in the same years to Germany and Austria-

Hungary were valued at £81,600 and £7,100 respectively. In addition, Germany's exports of paper, etc., to the principal colonial and neutral markets reached £3,602,850, those of Austria-Hungary £770,055, and those of the United Kingdom to £2,488,357. In 1912 the total value of German exports of paper, etc., to the British Empire, including Egypt, was something like £1,525,600; and those of Austria-Hungary in 1913, £165,945. It will thus be seen that the Dominions over which the flag of England flies were a rich field for commercial enterprise on the part of the paper and board manufacturers of the Central Powers. In no other country was Germany presented with such a market for her manufactures.

The various descriptions of paper, pasteboard, and cardboard imported by the United Kingdom alone from Germany were numerous, and are classified under no fewer than eighteen groups. Packing paper, including tissues weighing more than 30 grammes per square metre, and yellow straw paper, heads the list, being of the value of £492,000, coloured papers coming next at £168,400. Printing papers followed to the value of £140,600, and other products and their values were: Wallpaper, £72,500; pasteboard (imitation leatherboard), strawboard, wrapper-board, peat-board, etc., £65,300; parchment paper, £53,700; tissue paper (not used for packing), £47,200; paper and cardboard, punched or stamped out, £43,800; crude photographic (not treated with baryta), felt paper, etc., £34,700; gelatine paper, tracing paper, blue paper, fly-paper, test and other chemical paper, £28,700; lacquered paper, paper coated with scales of mica, glass, or wool, etc., £19,600; pasteboard of all kinds coated with white or colours with paper pasted on, varnished, etc., painters' boards, etc., £18,600; glazed boards, etc., £8,600; paper and cardboard covered with spun material, etc., £6,400; pasteboard impregnated with asphalt, for roofing, etc., ship felt for caulking, £3,000; slate paper, smoothing and polishing paper, £2,100; and vulcanised fibre, £1,100.

Austro-Hungarian exports of paper, etc., to the United Kingdom in 1913 embraced the following: Cigarette papers (plain and ribbed), £15,670; copying paper, tissue paper, etc., £6,820; packing paper (dyed and not dyed), £6,860; pasteboard of wood pulp, £4,745; drawing paper, artists' boards, and copper-plate printing paper, £2,400; lace and other perforated paper, £1,670; printing paper, £1,130; parchment paper, £395; coloured paper, etc., £190; common pasteboard, £110; fine cardboards (cartons), £40; all other cardboards, £20; wallpaper, £20; and various other papers not specially mentioned, £3,230.

Raw Materials, Labour, etc.

Coming to the question of our supplies of paper-making materials—wood pulp, esparto and rags—for which we are mainly dependent upon outside sources, comparison with the returns for 1913 shows that this country's imports of rags, which are used in the manufacture of the best classes of paper, declined last year by over 62 per cent., while in esparto there was a fall of nearly 33 per cent. As a consequence the difficulties of manufacturers of the better classes of paper have been, and are, extremely serious. Rags have materially advanced in price, and the increasing paucity of the supply foreshadows probable further advances. At the moment it is impossible to quote with any degree of certainty for any grade for a period ahead. Foreign rags, I understand, are practically unobtainable, while the demand for rags, ropes, bagging, and waste-papers of all kinds is very strong.

With regard to esparto, of which in normal times something like 200,000 tons is annually imported, great inconvenience and anxiety have during the past year been experienced through lack of supplies. About 50 per cent. of these come from Algeria and about 20 per cent. from Spain. Last year there was a shortage of 60,000 tons, which was chiefly due to the totally inadequate supply of transport, though a contributing factor was the diminished production of esparto in the growing countries. According to Messrs. Ide & Christie, "all varieties have shared in the shortage, but not all in the same proportion, the greatest falling-off, relatively, having been in Tunisian." Generally speaking, the course of the market has been steadily and persistently towards a higher level of prices, and the question of transport becomes increasingly serious day by day. Freight rates have been quadrupled since August, 1914, while the lack of tonnage and delays in loading are paralysing in their effects.

The record of the last two years is much more satisfactory when we come to consider the supplies of chemical and mechanical pulp. These have practically been maintained at normal levels, the returns for 1914 being actually 12,500 tons in advance of those for 1913, and those for 1915 being only 23,700 tons less than two years ago. Britain's command

of the sea is nowhere more clearly demonstrated than in the fact that, the German fleet notwithstanding, our supplies of wood pulp from the Scandinavian countries were in 1914 nearly 2,000 tons in advance of those in 1913, while last year they were actually 16 per cent. more than two years ago. In pre-war times our purchases of unbleached chemical pulp from Germany averaged 33,000 tons annually, but British paper manufacturers have suffered little, if any, inconvenience from the cessation of supplies from the Fatherland. Prices of all kinds of wood-pulp have undoubtedly advanced, partly owing to the increased cost of insurance and freight and partly to the greater cost of production in the exporting countries. Roughly, sulphite pulps have risen by from 60 to 70 per cent., and the price of mechanical pulps is nearly double the figure attained before the war.

Then, in addition to the increased cost of what I may describe as the staple raw materials, other factors operating in the direction of forcing up prices of paper, etc., are to be found in the greatly increased cost of coal, labour, chemicals, dyes, felts, wires, machinery, etc. Some of these had already begun to make their influence felt before the outbreak of war, and in this connection it may be mentioned that under the ægis of the Paper Makers' Association of Great Britain and Ireland something was done through mutual action and co-operation between competing firms to remedy what was undoubtedly becoming an intolerable situation, the continuance of which would render the paper-making industry of this country no longer a sound commercial proposition. The increased cost of coal and labour particularly had already compelled British paper manufacturers in self-defence to seriously face the question of advancing the prices of their productions, when war brought other difficulties in the train of those which may have been considered mainly domestic. Quite a number of subsidiary substances used in the process of the manufacture of paper became difficult and expensive to procure. The dye problem, for instance, quickly became acute, so much so that heavily-coloured papers have been to a very large extent discarded, the manufacture of those of lighter tints being resorted to from reasons of economy. Aniline and other synthetic dyes had been imported almost exclusively, if not entirely, from the Continent, and the extent of the shortage which developed may be estimated from the fact that, while imports in 1913 amounted to 283,027 cwts., the quantity obtained by this country last year was only 5,431 cwts. Dyes which used to cost about 3*s.* per lb. rose to 20*s.* and 25*s.* per lb. Some colours, too, which in the first half of 1914 were quoted at 1*s.* 6*d.* to 1*s.* 9*d.* per lb., have been sold at 60*s.* and 65*s.* per lb. Efforts are being made, chiefly through the agency of British Dyes, Ltd., a great concern fostered by our Government, to manufacture these dyes in this country, but naturally some time must elapse before we can expect the home production to meet the requirements of the textile, paper-making, and other industries of the United Kingdom, though there seems little doubt that we are gradually attaining a position of independence in this respect. But here again is another unfortunate result of British conservatism and prejudice, remarkable, too, when it is borne in mind that an Englishman (Sir William Perkin) invented aniline dyes from coal tar in this country, though it was left for German scientists to develop the principle and establish an industrial monopoly upon which every manufacturing country in the world has become more or less dependent, incidentally producing in Germany many multi-millionaires.

Chemicals, such as sulphate of alumina, powdered bisulphate of soda, sulphate of barium, and anhydrous sulphite of alumina, formerly obtained from Germany, advanced greatly in price, and certain classes of glue and gelatine and other sizing materials, in which Germany had almost a monopoly, became hard to obtain. Bleaching powder has also been scarce, and quotations which reached about £5 10*s.* before the war rose to £7 10*s.*, and afterwards to £10 and £14 per ton. Indeed, buyers have been heard of offering as much as £25 per ton, without being able to obtain what they required. Government requirements and the stoppage of German and Belgian competition were undoubtedly the chief causes of these great advances. Alkali, for which this country has been famous, has had so many calls upon it through the absence of foreign competition that it has advanced materially in price, and manufacturers have for many months experienced much difficulty with regard to transport both by sea and rail. Freight room in coastwise steamers became unobtainable, and the supply of railway waggons has been nothing like equal to the demand, while even after loading enormous delays have occurred in transit.

In this connection I should like to pay a tribute to the loyal and patriotic manner in which such world-famous firms as the United Alkali Co., Brunner, Mond & Co., the Castner-

Kellner Co., and the Ammonia Soda Co., Ltd., have treated their customers. They have all systematically refused large and tempting offers of new business from various foreign countries, considering it to be their duty to keep all their paper-making customers well supplied. Indeed, I believe that in order to ensure stability of business in this country they offered all users of bleaching powder three years' contracts at normal prices, of which considerate offer the bulk of consumers naturally took advantage.

Prices of caustic soda also have gone up to a high figure. I am informed that nominally the advance since the outbreak of war is about £3 10*s.* per ton, but sales have been heard of which show advances of at least £15 per ton. There is no doubt that there is a shortage all round of caustic soda, and so long as this continues prices are bound to rule high, and naturally those paper-makers who are dependent upon caustic soda alone will suffer greatly.

Zinc plates, extensively used by paper-makers for glazing, were chiefly the production of Germany, and resort in some cases had to be made to the use of thin nickel-faced steel plates, which I was instrumental in advocating early last year. They are, of course, more expensive, but are certainly more durable.

Paper-machine wires also became scarce, and prices have for some time been much higher than in pre-war times. The Germans had captured the bulk of the paper-machine wire business, their price being about 8½*d.* per square foot for export, taking care to make their own paper-makers pay a good price for their wires. But worse than this, they had practically cornered the manufacture of the drawn wire used by the British and most other paper-machine wire makers.

A considerable and increasing business was done up to the declaration of war with Germany and Austria-Hungary in woollen felts for clothing paper-machines, the same *modus operandi* being employed as in the case of the paper-machine wire weavers.

With regard to China clay, difficulties have arisen, not so much as to production but as to railway transport, and prices generally have not advanced so much as might have been anticipated.

An important and steadily developing trade was being done by the German engineers with the paper-mills of the British Empire, notably in sheet, friction, and glazing calenders of all kinds used in the trade, a speciality in which the Germans excelled. The whole of the plants, I might say, used in British mills for coating paper and printing machinery to a large extent were supplied by German engineers as well as many other paper-mill equipment specialities made and supplied by German engineering concerns.

There is reason to hope, however, that British paper-mill engineers will in future command a more important share of orders for this machinery than in the past. During the last twenty years British engineers have played an increasingly prominent part in the equipment of paper-mills, and it is not too much to say that in skill, resourcefulness and workmanship they have proved themselves to be at least the equals of their Continental and American rivals. During the past year or more their plants have been chiefly engaged upon munitions work, but it is satisfactory to learn that the cessation of war's alarms is already being anticipated in numerous inquiries from neutral and allied European countries as well as China and Japan, the United States and Canada, and I have no doubt that a bright and prosperous future awaits the British paper-makers' engineer. This remark, by the way, should also apply to our electrical engineers, who have no reason to be ashamed of the work which they have carried out in the past in the installation of electrical plant in paper-mills.

Yet another important factor in the situation which has arisen has been the greatly increased cost of labour. I do not think it is overstating the case to say that wages in paper-mills have advanced by about 20 per cent. The shortage of skilled labour in paper-mills owing to our military requirements has also presented difficulties of a somewhat serious nature. In some mills output was temporarily reduced to a considerable degree, but this is steadily being remedied, and there seems no reason to doubt that British paper-mills are now so organised that these difficulties are rapidly disappearing, the skilled hands having been "starred"—that is to say, exempt from military or naval service.

Prices, etc.

The abnormal conditions of which I have endeavoured to give a brief outline have naturally tended in the direction of enormously increasing the cost of the production of paper. This, coupled with the growing demand and interference with supply, has necessarily involved an advance in prices. Stocks in this country were fairly large at the time of the outbreak of war, but almost immediately afterwards prices began to harden perceptibly. As a matter of fact, the general conditions governing

the situation could not be accurately predicted, for the position in many respects was without precedent. No one could estimate, for instance, how far and for how long supplies of raw materials and manufactured paper from abroad would be affected by the action of the German fleet, and our ideas as to what might happen were of the most crude and chaotic character. Panic, happily short-lived, actually began to seize many sections of the paper trade. "News," which had been sold at 1*d.* per lb., mounted to 2*d.*, and several other grades began to advance in price. Wiser counsels, however, soon prevailed, and the market quickly steadied itself. During the early months of the war prices went up only from 2 to 5 per cent., but as time went on further advances were made, and by the end of last year it might be said that the average advance in prices of the usual run of printing and writing papers was from 40 to 50 per cent. beyond those prevailing in pre-war times. White machine-glazed poster papers, which used to be obtained for about 18*s.* 6*d.* per cwt., rose to 30*s.*, but this may well have been due to the fact that the Government demand for this class of paper for recruiting purposes rendered it difficult for private consumers to obtain supplies. One may, therefore, incidentally suggest that with the advent of compulsion for the unmarried "shirkers" the necessity for recruiting posters disappears, and thus the situation with regard to machine-glazed printings is relieved. Cheap super-calendered printings, sold eighteen months ago at 1¼*d.*, are now being quoted at 2½*d.* and 3*d.* per lb., no guarantee being given as to exactness of shade; better-class super-calendered papers normally selling at 2½*d.* are being snapped up at 3½*d.* to 5*d.* per lb.; glazed tints at 3*d.* have displaced foreign productions at 1½*d.* "News" paper, obtainable at 1*d.* per lb. before the war, now costs 1¾*d.* and even 1⅞*d.* Even 2*d.* is being asked in some quarters. This is a serious matter for newspaper proprietors, whose expenses are increasing in every department. Printing costs are up from 10 per cent. to 15 per cent. alone, while the revenue from advertisements appears to be getting less and less.

Imitation art papers have risen during the last two or three months from 2¾*d.* to 4¼*d.* net, and art papers (coated) have advanced from 3¼*d.* to 6*d.* per lb., and practically all along the line prices are up. Manufacturers of brown papers are just now experiencing a phenomenally heavy demand, notwithstanding that quotations are nearly 100 per cent. higher than eighteen months ago. Wrapping and packing papers are, indeed, not unlikely to reach famine prices, seeing that manufacturers are quite unable to meet the huge requirements of the public within reasonable time. Speaking as a large consumer of paper and with a lifetime experience of the paper trade, I must say I view with alarm any undue tendency to raise prices. As it is, the present prices are bound to result in a greatly restricted consumption on the part of newspaper, magazine, and book publishers.

The scarcity of boards used by our paper-boxmakers and the consequent increase in the price of same is handicapping our boxmakers not a little; also the high price of girl labour, brought about by the tempting wages to be earned in the munition factories. The same trouble is also to be found in the expensive business of paper-bag making.

The Restriction of Imports of Pulp and Paper.

Since preparing the foregoing portions of this paper the paper trade of this country has reached a crisis of considerable gravity. This arises (1) from the action of the Swedish Government in prohibiting the exportation of chemical pulp, and (2) the decision of our own Government to restrict imports of wood pulp and other paper-making materials and manufactured paper in order to relieve the pressure upon this country's shipping facilities. It is not my intention to investigate the reasons for these important steps, but rather to estimate the effect upon the British paper-making industry and paper trade. As to the Swedish embargo on chemical pulp, I would, however, say that, without disputing Sweden's right to take any steps she may deem necessary in protecting her own interests, I share the views of many others in this country that her prohibition of exports of chemical pulp savours very much of bluff, and is not in the best interests of the Swedish people.

That, however, is a matter which must be left to the judgment of Sweden herself, and all that we are called upon to consider is the influence of the embargo upon our paper-making, paper-selling, and paper-consuming trades. Adopting that view, the Swedish prohibition is overshadowed by the larger policy upon which the British Government have entered in the restriction of imports of all paper-making materials and paper, the effect of which will undoubtedly be serious and extensive.

At this stage let me pay tribute to the patriotic

attitude adopted by the Paper Makers' Association of Great Britain and Ireland in asserting that if, in the opinion of his Majesty's advisers, it is necessary to curtail the import of raw material and the export of the manufactured article, in order to release shipping for our national needs, the trade which in a corporate capacity it represents will cheerfully acquiesce in the arrangement. Our hearty concurrence with that attitude, however, need not prevent us examining for a few moments the effect of the Government's policy upon the British paper-making industry and the allied trades.

In this connection it must not be forgotten that just as wood pulp, esparto and rags are the raw materials for the manufacture of paper, so paper is the raw material for the production of numerous commodities which enter largely into the daily life of the people. It has been somewhat of a revelation to me to realise the widespread ignorance which has hitherto prevailed as to the manifold uses of paper. To that important individual, the man in the street, paper was mainly associated with the production of newspapers, books, magazines, etc., writing and wrapping papers; but, as a matter of fact, there are many distinct industries upon which great hardship will be inflicted by the curtailment of their supplies of paper and boards. Among these may be mentioned those devoted to the manufacture of paper boxes and paper bags, sand paper, cop tubes, slippers, loom and Jacquard cards, cartridge cases, cigarettes, paper collars, greeting cards, gun wadding, insulators, photographic mounts, and many other articles, while the bookbinding industry must not be omitted. It will thus be seen that any interference with their supplies of paper and boards must seriously affect many important and useful trades.

Upon British paper-makers the restriction of imports of pulp and other raw materials must press heavily, particularly upon those who have laid down machinery and plant for the production of certain kinds and qualities of paper which, prior to the war, were not made in this country at all. Many of these, I believe, have been able to capture a great deal of what used to be German trade, and it is, therefore, regrettable that the necessity should have arisen for interfering with the development of what may be regarded as a new feature in British paper-manufacturing operations.

Broadly speaking, it is doubtful whether any action of a similar character which the Government could have taken would have exerted so paralysing an effect over such a wide field, and would have injured so many undertakings as in the case of the paper-making industry. There are already signs of confusion in almost every quarter where paper is used, and particularly where German specialities have not yet been replaced or supplanted by British products. The restriction of their supplies of necessary raw materials comes, too, at a time when British paper-mills, notwithstanding the reduction of their operative staffs, are working at practically their full capacity, and the reduction of their output by a considerable percentage must inevitably entail hardships of a serious nature.

The Government's action must, of course, lead to the necessity of the exercise of strict economy in the use of all kinds of paper. Stocks are now very large, but they are not inexhaustible, and the general public must resign itself to many sacrifices. Our newspapers will undoubtedly be reduced in size and embrace fewer editions; our business and personal correspondence may have to be curtailed; and in numerous other directions which I need not trouble to specify the watchword in all departments of public, commercial, and private life must be—economy!

At the time of writing, it is not known what the scope of the Government's action will be, but as an indication that some drastic step is contemplated, it is significant that inquiries are being made among printers and others in this country with a view to ascertaining the extent of their stocks of paper.

The Influence of Freights.

If time permitted it might be worth while to say something regarding the difficulties and the costliness of freights. This, as a matter of fact, is one of the most important influences affecting the paper trade of the world to-day. It is no secret, of course, that the real difficulty is in regard to "bottoms"—in other words, ships; and this, together with the equally serious problem of railway transit, is, as probably most of you are aware, receiving the serious attention of our Government at this moment. Whilst making every possible allowance for the imperative demands of the Government, a condition of things we must all loyally respect, an authority recently commented somewhat strongly on the avoidable delays, particularly in regard to shipping.

It seems to be admitted that there has been a good deal of muddling and misuse with regard

to our shipping—in other words, we have not put it to its best use; and surely there must be something wrong if, as is stated, roughly 25 per cent. of our ships' time is occupied in dock upon work incidental to discharging and loading.

No doubt labour difficulties and extraordinary demands on space and accommodation have much to do with this, but it is suggested by those who should know that we are by no means up to date, particularly in certain ports, in regard to labour-saving appliances and the application of the most modern haulage appliances. Misapplication of existing organisations, incompetency on the part of higher officials appointed by Government to supervise the mercantile marine of this country, coupled with lack of experience, is largely responsible for a great deal of "muddling."

It is difficult to appreciate fully how much we owe to the efficiency and activity of our Navy, and, bearing this in mind, it is unfortunate that the unquestionable advantages we owe to this all-important superiority should, in a sense, be wasted by delays which are apparently to some extent quite unnecessary and avoidable.

All traders also realise the terrible condition of things arising from the congestion of our railways. I have no desire to be unduly critical at a time when the demands of our fighting forces must take precedence. Still, I do feel that manufacturers, merchants, and consumers have just cause for complaint in regard to some of the extraordinary delays on our railways, delays which have caused and are causing tremendous inconvenience and enormous losses. It is not consoling to be told that matters may even become worse. If some of the tales I have heard regarding the time occupied in carrying urgent matter a comparatively short distance are correct, and I believe they are, in my opinion it is time that the question should be considered by a competent body, as the opinion seems to be general that, without interfering in any way with Government demands, a great improvement might be made in regard to this all-important matter, which has had a very serious effect on many paper-mills, and on those who rely on regular supplies of paper for carrying on their businesses.

In regard to shipping, it is rather refreshing to have the authority of Sir Walter Runciman "that the cost of freightage is not only scandalous, but a crime." This admission, coming from such an eminent shipping man, is, to say the least, significant.

THE BRITISH EMPIRE'S RESOURCES IN PAPER-MAKING MATERIALS.

Seldom has this country's dependence upon foreign sources for its supply of raw materials been more forcibly brought to mind than by Sweden's action in prohibiting the export of chemical pulp, and never has the nation been so vividly reminded of those vast resources which are to be found within the limits of the Empire which it has established. I need scarcely remind you that about nine months ago the Royal Society of Arts did me the honour of affording me the opportunity of submitting a paper on this subject, and perhaps you will pardon me for recalling that on that occasion I mentioned that our dependence upon the Scandinavian countries for supplies of chemical and mechanical pulp had not been without a certain amount of risk to the interests of the British paper-making industries. I then urged that we should endeavour to supplement our foreign sources of supply with those which are awaiting exploitation and development within our own world-wide Empire, and in the course of my paper I dealt at some length with the wonderful potentialities of the Dominion of Canada.

It is, however, unnecessary for me to traverse that ground again, except to state that the latest estimates of the Forestry Branch of the Department of the Interior show that the value of Canadian pulpwood in 1914 was placed at $60,500,000, an advance of $5,500,000 upon that of 1913. In the manufacture of pulp 1,224,376 cords of wood were used in 1914, and of this 68 per cent. was spruce, 25 per cent. balsam fir, 3 per cent. hemlock, and nearly 2 per cent. Jack pine, the balance being poplar. The production consisted of 644,924 tons of mechanical pulp, 217,550 tons of sulphite, 70,333 tons of sulphate, and 1,893 tons of soda pulp. These returns indicate that the production during 1914 of all kinds of pulp in Canada was nearly 20,000 tons below the quantity of wood pulp imported by the United Kingdom in 1915. It will, therefore, be seen that some time must elapse before Canada is in a position to furnish this country with even a moderate proportion of its supplies of either chemical or mechanical pulps, after satisfying its own requirements. And in this connection it must be borne in mind that Canada is steadily developing its own paper-making industry, and during the fiscal year ended March 31st, 1915, exported paper to the value of $15,478,338. During the same period the Dominion also exported more than 240,330 tons of chemical pulp, the great bulk

of which went to the United States, and nearly 223,000 tons of mechanical pulp, of which 64 per cent. was absorbed by the United States and 33 per cent. by the United Kingdom.

It would, no doubt, be possible for Canada to increase materially her exports of wood pulp to this country at the expense of those to the United States, but under present conditions, when ocean freight rates are so high, it is probable that the cost would be greatly in excess of that from the Scandinavian countries. At present Canada is not in a position to take the place of Sweden as one of the two main sources of our supply of wood pulp, and cannot be expected to do so until after the expenditure of a large amount of capital in the erection and equipment of new pulp-mills and in the acquisition of pulpwood areas. All this must necessarily be a matter of time. In the case of sulphite pulp, of which Great Britain imports so large a quantity from Sweden, it must not be overlooked that at present Canada has only three mills, I believe, manufacturing it solely for exportation, and these produce in the aggregate less than 400 tons a day. In addition, there are a number of paper mills making sulphite for their own consumption, which can afford to export surplus quantities to a small degree. However, the extraordinary attitude assumed by Sweden will, I am certain, act as an incentive to Canadians to attract British and other capital for the development of the wood-pulp business in the interest of the Mother country.

With respect to Canada and the possibilities of Canada in regard to the wood-pulp question, I may say that I recently had the pleasure of meeting Mr. J. E. A. Dubuc, who is admittedly the greatest authority as a wood-pulp manufacturer in Canada. Mr. Dubuc has been in this country within the last day or two, and he was good enough to speak quite freely on the subject to me. He said that, as far as the export business is concerned—I am now referring to chemical wood-pulp—the three mills producing chemical pulp have invariably a surplus over and above their own requirements for their own respective mills. I put several leading questions to Mr. Dubuc, and said: "Speaking with regard to chemical pulp, what do you consider are the possibilities with regard to increasing the production for export?" Mr. Dubuc replied, without any hesitation: "If the money could be put up to-morrow, I will guarantee that our production of 35,000 tons on the St. Lawrence, and the proposed production of the Ha-Ha Bay mill (another 35,000 tons), could, if necessary, easily be doubled."

I asked Mr. Dubuc how long it would take to achieve this, and he made the following interesting reply: "Well, I would undertake to furnish round about 200,000 tons of sulphite wood-pulp (including the present output) per annum in two years from now."

I mentioned the fact that certain paper-makers had expressed a fear that the supplies from present sources might possibly be interfered with by embargo or from other considerations after the war, and Mr. Dubuc said: "If the necessary capital were forthcoming, mills could be built on sites at present in my mind's eye, and the capabilities of these mills would, if necessary, be not less than half a million tons per annum, and this quantity could be drawn from just two sections of Canada, leaving out of consideration the enormous resources which, as you know, include illimitable timber reserves, stretching even beyond the pale of civilisation."

The general effect of Mr. Dubuc's replies were, without any qualification, that within a comparatively short time, providing the capital were available, Canada could unquestionably produce enough wood pulp for the paper-making requirements of the world.

Mr. F. E. R. Becker, of the firm of Becker & Co., another well-known authority on wood pulp, who was present when this conversation took place, endorsed the opinions Mr. Dubuc had expressed, and he observed that Chicoutimi, the great Canadian undertaking at present devoted to the production of mechanical wood, has 436 ft. fall, and has developed not more than 170 ft. of this enormous power. Mr. Becker added that Chicoutimi produces on this present development 350 tons dry mechanical pulp per day, and if the 436 ft. were developed Chicoutimi would turn out 1,000 tons dry per day, and 300 working days on this calculation would mean 300,000 tons dry mechanical pulp.

Mr. Becker added that this could be achieved in eighteen months, and it would mean more pulp of this class than the world uses in the open market.

It was also mentioned that, as regards the timber available, the Peribonca (Lake St. John district) alone contained 10,000 square miles of excellent timber, so that the timber problem need cause no concern.

I asked Mr. Dubuc how the shipping problem was to be solved, assuming these great developments were realised, and he said that if the British consumers were prepared to make ten-year contracts, as he had no doubt many of them would be prepared to do, the shipping

questions could readily be settled. He also said that the available country round the Saguenay and the Gaspé Rivers alone could provide all the pulp required by British mills.

I was interested to have this information on such high authority, for no persons have a more thorough knowledge of the subject than the two gentlemen I have mentioned.

What I have said with regard to Canada applies, in my judgment, with equal force to Newfoundland and Labrador, both of which are rich in pulpwood, and will eventually become enormous sources of supply.

Time does not permit of more than a passing allusion to those which are available in India, where vast quantities of bamboo, Savannah, and other grasses can be utilised in the production of paper; in Trinidad, British Africa, and the Federated Malay States. It is indisputable that within the borders of the British Empire there are enormous resources in paper-making materials, but their application to the requirements of British paper-mills cannot be effected in a day or a year. Many considerations enter into the question of their adaptability to the manufacture of paper in this country, and not the least important is that associated with the diverse mechanical methods with which wood pulp and pulp made from grasses, etc., are treated.

The question of utilising the Empire's resources in paper-making materials is, therefore, not quite so easy of settlement as some newspaper correspondents seem to imagine. That it will eventually be satisfactorily settled I have no doubt whatever, but only after the passage of some years and the expenditure of a large amount of capital.

If the Scandinavian wood-pulp producing countries show a disposition after the war to place embargoes on the export of wood pulp to this country, then, naturally, the problem of utilising the British Empire's resources in paper-making fibres will be solved much sooner.

In conclusion, I would add that the enormous virgin forests of Russia have yet to play a very important part in the manufacture and exportation of sulphite wood-pulp to this country. The Germans, by the erection of enormous plants in the Russian Baltic province of Courland, have produced for some years past, on a large scale, excellent cellulose from Russian pulpwood, the quality being fully equal to that of Scandinavian chemical pulp. I believe, however, these huge German mills have been destroyed by the Russians in the prosecution of the war.

It is probably within the knowledge of most people in this room that the *London Gazette* of yesterday evening contained a Proclamation prohibiting—

All materials for the manufacture of paper, including wood pulp, esparto, grass, and linen and cotton rags.

Paper and cardboard (including strawboard, pasteboard, millboard, and wood-pulp board), and manufactures of paper and cardboard.

All periodical publications exceeding sixteen pages in length imported otherwise than in single copies through the post.

With regard to the proposed restriction of imports, I hear, unofficially, it is probable the Commission will decide on a restriction of $33\frac{1}{3}$ per cent. If this is so, I think it may be considered a satisfactory compromise.

DISCUSSION.

THE CHAIRMAN (Lord Burnham) said the paper was an interesting and exhaustive one on a subject that had now become one of the burning questions of the day. A little while ago probably nobody in the country anticipated the steps that would be taken by the Government to restrict the importation of paper and paper-making materials. There was no more curious problem in psychology than the attitude of the public mind in this country to trade questions. Public ignorance was abysmal. It was not thought that trade questions ought to be considered by the general public, unless some political considerations were immediately involved. There was no disposition here, as in the United States, to hold constant conferences to consider matters of world trade in all their bearings, nor were the people instructed in the facts and figures as people had been for the last fifty years in the State-ridden Empire of Germany. Consequently, when a question like the restriction of the paper trade came into public prominence, there was absolutely no sort of appreciation on the part of the general public as to how matters stood or whither they would tend. The author had said that the public ignorance in regard to the paper trade astounded him, but he (the speaker) could not say that it astounded him; he verily believed that the general public imagined that the only trade in paper was that of the daily and weekly journals. Many people considered that it would not be a bad thing if a tax were placed on the shoulders of newspaper proprietors who were selling an unusual number of copies of their issues owing to war conditions. Of all the war fallacies he did not suppose there was a greater one. In the first place the war had spelt a huge loss, in some cases positive disaster, to the newspaper trade; but, apart from that, the newspaper trade was but a small part of the national industries which were concerned with the importation of paper and paper-making materials. The

paper industry was not only an essential trade in the country, it was practically a fundamental trade. Not only did it supply by means of books and papers the intelligence with which all other trades were carried on, fixing the price as it were of the intelligence department of British trade and industry, but paper was now used in so many trades that it ramified throughout the whole of the commercial and industrial organisations of the country and the Empire. He had been told only last week that owing to the sudden restriction placed upon the paper trade, the hosiery trade was suddenly arrested by the fact that it was impossible to obtain paper in which to wrap stockings. Many such examples could be given. It was an open secret that paper was used in making shells; the munitions trade of the country depended upon paper to a considerable extent, and thus paper was directly as well as indirectly the basis of a war industry. Without arguing the point as to whether restrictions ought or ought not to be made, he might say that it was very regrettable that the public—and he thought Parliament too—was not able to consider the question with a full knowledge of what it meant and whither it tended. It was well known that the necessity for restricting the importation of paper and paper-making materials had arisen from the want of bottoms in which to carry the general trade, and particularly the essential trade supplies, of the country, and not only of the country but of the whole of the nations which were included in our great alliance. It was not only a matter of our own shipping being taken for Government purposes; undoubtedly if neutral ships were released from part of their present burden of trade they would be available for other and perhaps more necessary purposes. The economic experiments in which the country was embarking under the stress of war were certain to lead to results which would be, if not damaging, at least disadvantageous to the country, and would have a serious, crippling effect upon many of its industries. It was a disadvantage, of course, that the export trade in paper and other kindred products was for the time put an end to, because, as was known on the highest authority, the greater our export trade the better for the balance of our trade all over the world, the better for our exchange, and the larger the resources available for war purposes. Therefore in itself, apart from the question of shipping, the prohibition of exports was a serious matter. In this country we produced no paper-making materials of first quality; the only thing that might be classed as paper-making material was the waste of the paper and other trades. That made the matter of price particularly difficult. Again, on the political side, nobody viewed with pleasure the curtailment of our trade with neutral countries, which was very largely to their advantage. As was well known, Sweden and Norway lived upon their timber, exported for various purposes in a raw state, and converted into wood pulp and paper as a finished article. Therefore, no one cared to see the present state of things, even though it was admitted that the first duty of the Government was to secure the greatest amount of shipping for the primary purposes of the war, both for our Allies and ourselves. Generally, the consequences of restriction were likely to be serious, but economy and thrift in the use of materials might do something to repair the damage, and if the information the author had was correct, the proposal to diminish the supplies by only one-third was a great improvement, from the point of view of those concerned in the paper trade, upon the first Government plan, which was said to be a diminution by 50 per cent. It would be much easier for the trade to readjust itself to the conditions if it had not to face so large a discrepancy. Looking to the future, there was no doubt that we ought to do our best to put our trade on an Imperial foundation. Roughly speaking, Norway and Sweden supplied nearly 75 per cent. of the raw material of paper, and although we did not wish to diminish trade with them we did wish, under the stimulus of war, that after the war our own dominions should have the lion's share. The proper meaning of economy was the "Law of the house." The Empire was a house of many mansions, and therefore it should be our aim to see that the Empire secured the greater part of the increase that was bound to come when we were supplying ourselves and the other parts of the Empire with the paper and paper products hitherto imported so largely from foreign countries. The whole question of Imperial trade was being looked at in a new light and from a different angle. We should not concern ourselves with the abstract merits of Free Trade and Protection, but should seek that security which could only be effected by making the Empire self-sufficient in all the main industries and the necessities of life. Paper was a necessity of life, a necessity in the larger sense; it was a necessity of communal life and of individual life; and those who were concerned with the paper industry must do their best to see that its foundations were so well and truly laid in the future that the industry could never be placed in the predicament it was now in, dependent, apart from the action of the Government, upon the will of foreign powers to limit or altogether to curtail the supply of the necessary material upon which the industry lived and thrived.

MR. CLAYTON BEADLE said the enormous development of the paper trade during recent years created a far greater problem during this time of war than it would have done in any previous period when the nation had been at war. One of the largest mills in this country produced more paper to-day than the whole of the United Kingdom produced a little more than one hundred years ago. During the Napoleonic wars all the Government of the time seemed to be able to do in the way of conserving the supply of rags was to prohibit the burial of the dead in linen shrouds.

The author had read his paper at the psychological moment; in fact, the moment was almost too opportune to enable the subject to be adequately discussed. He had heard of a case recently where, in order to secure a quick delivery, a penny a lb. was given, which amounted to about 30 per cent. advance on the price contracted for. During the last month he had been asked by cable from the colonies to ascertain whether certain papers were procurable in this country, and he was sorry to say that at the moment—although it was not true a month or two ago—the only answer was that they were not obtainable, and there was no possibility of finding out when the manufacturers here would be in a position to supply. The author had referred to several kinds of paper formerly manufactured in Germany, which had been already successfully produced in this country. One class of paper that had been exceedingly difficult to make, but the making of which had been completely mastered, was filter paper. Photographic and other special papers had also been produced by certain enterprising manufacturers who were producing other classes of paper before the war. There were still papers which came almost exclusively from Germany not yet manufactured in this country. The question of coloured papers was an extremely difficult one, and for certain purposes the use of coloured paper would have to be set aside until the termination of the war. Although the United States were making paper almost entirely for their own use, the cost of the manufacture of pulp and "news" in Canada was considerably less than the cost in the United States. That was largely due to the fact, he believed, that the supplies had not been depleted in Canada to anything like the same extent. The author's figure of 10,000,000 tons as the world's production of paper had been confirmed by another authority. The rate at which the consumption of paper had increased in different parts of the world was without precedent, and the increase was going on to an alarming extent, chiefly owing, he thought, to the enormous wastage from paper being so plentiful. He believed the exportation of rags had been prohibited as from March 1st. The Americans had been competitors in the rag market, and it had been very much to the detriment of buyers in this country that Americans had come over and bought large supplies and thus considerably inflated prices. It was therefore a good thing that the exportation was to be prohibited.

Mr. H. Whorlow (Secretary of the Newspaper Society) said he had been very much interested in the statement of the author as to the intention of the Government with regard to the proportion of imports to be restricted. The same information had reached him on the previous day from a very reliable source, and if it was true it would go a very long way towards relieving the great anxiety under which the newspapers of the country laboured at the present time in anticipation of the difficulties of a threatened famine. He had just issued a circular giving a general statement of the present position of affairs, and in that circular had mentioned the proportion of 50 per cent. If the reduction was to be to one-third, he believed it would be to a very large extent due to the efforts of Lord Burnham himself and the stand he took at an early stage of the matter. When the Paper Commission met they would have many difficult problems to face, one of which would be to devise some means whereby publications of all kinds would get a fair proportion of paper to meet their requirements. There had been some talk of a compulsory reduction in the size of newspapers, but it seemed to him it was very unlikely that the Commission would go to work in that way. When the war first broke out there was some panic, and many papers, especially weekly papers, reduced their size from sixteen to eight pages, and from eight pages to four pages, while others continued to publish the same size as before. In a town where, say, three newspapers were published, if one had cut down its size while its contemporaries continued to publish on the old lines, that fact ought to be taken into account when the allotment of supplies was made, if there was any intention compulsorily to limit size. An ordinary eight-page weekly paper could not do with four pages, as it would be impossible to publish advertisements. Newspapers which had anticipated economy should not be put on the same level in allotting supplies as those which had made no reduction in size at all. It was a satisfactory augury for the success of the Commission that everybody entertained the utmost confidence in the fairness and ability of its Chairman, Sir Thomas Whittaker.

Mr. Percival Marshall said that as one of the unfortunate paper-consuming public he naturally regarded the present situation as being very serious, and he had felt somewhat relieved when the author said that there was a possibility of the original restriction being relaxed. If only one-third of the paper supply was to be cut down then the economies which might be effected in many ways, by newspapers and other large users of paper and by the public generally, might go a long way towards making up the deficit. With regard to the point of the Swedish restriction being a piece of diplomatic bluff, it occurred to him that it might be a very good thing if the author's remarks upon the possibilities of Canadian production could be brought in a suitable way to the notice of the Swedish Government. No doubt they were quite aware of the possibilities of Canada in the way of producing paper-making materials, but the author had thrown some further light on the subject, and the conversations he had had with Canadian representatives as to the readiness of Canadian manufacturers to fill the gap might, if brought to the notice of the Swedish authorities, have some effect upon them. It might be possible for some of the editors of the

country to set an example to the public in economy by allowing their contributors to write on both sides of the paper.

THE CHAIRMAN said a difficulty would then arise with the compositors, who did not allow writing on both sides of the manuscript.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to the author.

MR. S. CHARLES PHILLIPS, in reply, thanked the audience for having borne so patiently with the length of the paper. He could assure them that the only trouble he had had was as to how much he could get through in the time. He thanked Lord Burnham for presiding. Everyone was delighted to see his lordship. Personally, he took it as an exceedingly delicate and kind compliment to himself, because Lord Burnham was the proprietor of the *Daily Telegraph*, one of the largest, most important, and most influential papers in the world, a paper of which the country was proud, and he was also a very large and important paper-maker, as the *Daily Telegraph* possessed its own mills at Dartford.

MR. PHILLIPS has since sent the following note on the question of rag supplies:—"A gentleman who is admittedly a leading authority on the subject of rags for paper-makers' requirements, and on other classes of paper stock, tells me that the collections of both rags and waste-papers have fallen off to a considerable extent, owing largely to the fact that a considerable number of small collectors have gone to the war. I also learn that the question of price for rags for paper-making has almost ceased to be a matter of consideration, and that 'send on the goods and charge whatever you think is reasonable' is quite a common instruction on the part of paper-makers nowadays. This condition of things is, of course, directly attributable to the war, and my informant observes that it would be a very pleasant thing for the dealers if they had the material to dispose of on these terms. I also learn on the same authority that it is questionable whether the proposed restriction on the export of linen and cotton rags and waste-papers will help matters to any appreciable extent. It is an interesting fact that shortly after the war started common waste-papers were a complete drug on the market—in fact, a large London dealer said he was prepared to give away barge-loads for nothing. Latterly, however, owing to the demand first from Holland, then from France, things have changed materially."

CORRESPONDENCE.

THE ORGANISATION OF SCIENTIFIC RESEARCH.

DR. J. A. FLEMING, F.R.S., writes in reply to the discussion on his paper read at the meeting of February 9th:—"I esteem myself fortunate in having been able to elicit from so many eminent scientific men expressions of opinion on this subject which they have deeply studied. It is also satisfactory to find that there are several points on which we are all in general agreement, even though differing on others. One of these is that it is essential to distinguish very carefully between the nature and aims of (1) pure scientific research, (2) technical or industrial research, and (3) practical or useful inventions. The public and the press only too frequently confuse them. As regards pure scientific research, from one point of view it is merely a delightful and interesting occupation or pursuit to those who have the necessary tastes and mental qualities, and if it had no other aspect there is no particular reason why the State should be called upon to assist it. But as a matter of fact it is the basis on which technical research and invention rest; and, moreover, the three, though broadly speaking distinct, shade into each other so finely that it is difficult to draw hard and sharp lines. Hence no nation can say it will only foster technology and invention, but leave pure science alone. The general principle has been accepted and acted upon that the State, that is the nation, should financially assist pure scientific research regardless of any immediate industrial applications as a matter of high public policy. The questions at issue are then—to what extent it should assist it, and by what means. My contention is that the State should do this only by putting funds for this purpose at the disposal of properly qualified scientific men or bodies and leave them to settle how they will employ it. The State should not meddle with details, and above all should not establish any bureaucratic control over pure scientific research. The very essence of scientific work is intellectual liberty, and science must not bargain away its freedom for any mess of State pottage. If a bureaucratic control of research is allowed to grow up, then it will not be long before those few who have the necessary gifts and powers of mind for making scientific discoveries or researches will find themselves bound hand and foot by bandages of red-tape, and their freedom crippled by a number of officials who might not have either the ability or the wisdom to do the right thing. Hence it is satisfactory to note that the opinion of most of those who have spoken in this discussion is decidedly against detailed control of research by Government committees or departments. The only safe way to assist it is by placing the necessary means in the hands of men who have already exhibited great capacity for doing scientific research. Personally I think that one good way of doing this is the creation and multiplication of such positions as the Research Professorships of the Royal Institution, in which opportunities for research are coupled with no other obligations than those of expounding at intervals to public audiences the results of investigations. Moreover, a life service to the nation in such a position should carry with it a right to a pension,

so that there should be no necessity for the occupants of these chairs to engage, as did Faraday and Tyndall, in outside teaching or consultative work to secure the means of independence in declining years. As regards younger men, I believe that a considerable extension of research scholarships, on the lines of the 1851 Exhibition Scholarships or Whitworth Scholarships, would prove a good national investment. It does not follow that such a scholar need seek to find his life-work in pure research, but he gets the opportunity of showing if he has abilities as an investigator; he also gets a training in research methods, and learns to run alone and get over difficulties by himself. In the last twenty years I have had seven or eight 1851 Exhibition research scholars working in my laboratory, and although their scholarship year or years has been occupied with pure research they have nearly all gone subsequently into positions in factories or works in which they had the opportunity of climbing up into good positions. These positions they would never have obtained but for the training they received in pure scientific research. Then, in the next place, as regards industrial or technical research, I agree with Mr. Swinburne and with Sir William Tilden and Professor Armstrong that it must be left to the technical manufacturers to settle. I therefore very much regret the unavoidable absence of Sir Robert Hadfield from the discussion, as in him we have one who speaks on this matter with authority, and if he had been able to be present he would no doubt have greatly extended the brief but interesting remarks he has made in his letter to me. With respect to the system of industrial fellowship inaugurated by Professor Robert Kennedy Duncan, to which I briefly alluded, I am not personally in favour of converting university laboratories into places for conducting too much commercial work; nevertheless, I have found it a great benefit to third-year students who have gone through the course work to take part in tests or researches made under commercial conditions. The chief business of the colleges should be to teach principles, but at the same time to give instruction or opportunities for learning how to apply them. As regards invention, I think we are also in agreement that the chief benefit the State can confer on scientific inventors is to let them alone. Beyond certain modifications in patent law which, as Mr. Swinburne says, speaking in the light of his great experience, should be settled largely by patentees and inventors, what is mainly required is that the politicians shall abstain from premature and unwise legislation. The manner in which certain scientific industries, such as electric lighting and traction and, as many think, telephony, have been handicapped, retarded, and injured by meddlesome and hasty legislation, is a story only too familiar to electrical engineers. But I hardly think that the time has yet arrived for the creation of a Ministry of Science. It would be a disaster of the first magnitude to have scientific research or its organisation in any way included in the atmosphere of party politics. It is difficult to see how any such post could be created and yet remain free and untouched by the struggles involved in political life. That very originality in scientific work which characterises our nation, which the Chairman has emphasized, is, I believe, a direct consequence of the intellectual and moral freedom we have enjoyed. Any bureaucratic control of science will imperil it. The German professor is in shackles to the State. Outside the limits of his own special work he has to do and say what the State tells him or he is a black-marked man. Hence I view with great trepidation proposals for the organisation of science which are based on the creation of Government control of details, and have urged here the organisation of science solely by scientific men. Professor Armstrong has said that my views do not appeal to him, though I am not quite sure what is the precise point on which he differs from me. At any rate I agree with him that the public school education must be reformed. In my opinion it is not merely a question of giving more time to science in schools and less to classics so much as elevating the whole tone of the teaching and quickening more an interest in intellectual things. The main absorbing interest in public schools hitherto has been the games. The intellectual life is relegated to a second place. After all the Government and the press merely reflect the thoughts of the people, and as long as the great mass of the nation think more of sport, games, fashion, amusement and politics than of the phenomena and structure of the world in which they live, science will be neglected by them. But, as Sir William Tilden said, we have received a horrible shaking up and are in a better frame of mind for it. One thing is perfectly certain: we have, as a nation, to set to work to make and manufacture scores or hundreds of things we have previously bought from Germany and Austria, and that will compel national attention to scientific matters hitherto ignored. Let me, in conclusion, thank the Chairman for his kind remarks, and the Secretary and Council for the privilege I have enjoyed of starting this interesting discussion."

It is to be hoped that Dr. Fleming's highly important subject will be widely considered and discussed, and I should like heartily to endorse his view that the organisation of scientific research is one of those matters that should be undertaken by scientific men themselves. In our country, unfortunately, the general public—including the average politician and Civil servant—are not much interested in science and have but little knowledge of it. It is altogether unsuitable, therefore, that the organisation of science should be left in their hands. If better attention were paid to scientific training at our public schools and universities this objection would be far less marked. One good result of the war will surely be to improve our defective training in science;

and I sincerely trust that the combined laboratory and workshop training will come into more general force for the preparation of young engineers, etc., more or less on the sandwich system that Dr. Fleming advocates. The present war being so largely one of science and invention, the future of the inventor is a matter of considerable importance. Up to the present time a large proportion of the things invented emanate from so-called professional inventors—the sort of man such as I once heard of as having the word "Inventor" written in large letters after his name on his visiting card, and even on his handbag! Unfortunately, it is found that the man whose sole purpose in life it is to invent—and to invent as speedily as possible—has very frequently had no practical experience or knowledge of the particular industry concerned in the invention; indeed, his inventions are far too general for that to be possible. Moreover, more often than not he has little knowledge of what has already been tried, and possibly patented, in the same field or with the same object in view. On the other hand, those possessing this knowledge, and through engagement in practical work being in the best position to invent, are liable to get too much into a groove as to the way of achieving desired objects. Unfortunately, too, it has to be added that our masters of industry do not, perhaps, encourage scientific and inventive research as much as they might well do or as much as they do in other countries more naturally interested up to the present time in scientific matters. The war should thereby have the effect of inducing within us a little more scientific enterprise, so that men of high scientific training and real inventive ability may be given the best opportunity of producing something really useful from our works for the benefit of those immediately concerned as well as for the nation as a whole. Meanwhile, the Scientific Intelligence and Information Bureau that Dr. Fleming speaks of would, I think, serve as a highly useful preliminary if brought into being with as little delay as possible; and I cannot help thinking that the Government would even now recognise the desirability of subsidising such an organisation if there was sufficient evidence of support from the right quarter. An institution of this kind ought further to render us independent of foreign-made goods both now and in the future.

CHARLES BRIGHT.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

FEBRUARY 23.—MISS H. B. HANSON, M.D., B.S., D.P.H., "Serbia as seen by a Red Cross Worker." SIR FRANCIS CHARLES GORE, K.C.B., Hon. Treasurer of the Serbian Relief Fund, will preside.

MARCH 1.—CHARLES DELCHEVALERIE, "Maeterlinck, Verhaeren et les Lettres belges."

MARCH 8.—CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Optical Appliances in Warfare." DR. R. T. GLAZEBROOK, C.B., F.R.S., Director of the National Physical Laboratory, will preside.

MARCH 15.—EDWARD PERCY STEBBING, F.L.S., F.R.G.S., Head of the Department of Forestry, University of Edinburgh, "Forestry and the War."

MARCH 22.—REV. P. H. DITCHFIELD, "The England of Shakespeare."

MARCH 29.—

APRIL 5.—ARTHUR S. JENNINGS, "Painting by Dipping, Spraying, and other Mechanical Means."

MAY 3.—PROFESSOR W. B. BOTTOMLEY, M.A., F.C.S., "Bacterised Peat."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

APRIL 6.—PROFESSOR WYNDHAM R. DUNSTAN, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India."

APRIL 27.—JAMES MACKENNA, M.A., I.C.S. (Deputy Commissioner, Myaungmya, Burma, and designated Agricultural Adviser to the Government of India), "Scientific Agriculture in India."

MAY 18.—SARDAR DALJIT SINGH, C.S.I., "The Sikhs."

COLONIAL SECTION.

FEBRUARY 28 (Monday, at 4.30 p.m.).—PERCY HURD, "Next Steps in Empire Partnership."

APRIL 11 (Tuesday, at 4.30 p.m.).—SIR DANIEL MORRIS, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland."

MAY 2 (Tuesday, at 4.30 p.m.).

Dates to be hereafter announced:—

R. W. SETON-WATSON, D.Litt., "The Balkan Problem."

W. A. CRAIGIE, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

VICTOR HORTA, Directeur de l'Académie Royale des Beaux-Arts de la Ville de Bruxelles, "Belgian Architecture."

PROFESSOR T. G. MASARYK, "The Slavonic Peoples."

G. P. BAKER, "Hindu Hand-painted Calicoes of the Seventeenth and Eighteenth Centuries, and their Influence on the Tinctorial Arts of Europe."

Cantor Lectures.

Monday afternoons, at 4.30 p.m. :—

J. Erskine - Murray, D.Sc., F.R.S.E., M.I.E.E., "Vibrations, Waves, and Resonance." Four Lectures.

May 1, 8, 15, 22.

Fothergill Lectures.

Monday afternoons, at 4.30 p.m. :—

Rev. Dr. Herbert West, D.D., A.R.I.B.A. (author of "Gothic Architecture in England and France"), "National and Historic Buildings in the War Zone: their Beauty and their Ruin." Three Lectures.

Syllabus.

Lecture III.—February 21.—*French Mediæval Sculpture.* Christian art that of a new-born society rising amidst a dying civilisation—Provençal sculpture, Arles, etc., decadent—Burgundian, full of life and imagination; but Classical influence traceable all through (Vezelay, Autun, Auxerre)—XIIth Century (Avallon, Bourges, N. and S. doors, Chartres, W. front). Elongation of statues, architectural not ignorant—Individual types, elaborate detail. The sculpture scheme of a XIIIth Century cathedral (Laon, Notre Dame, Amiens, Reims). The Judgment door (Autun, Notre Dame, Amiens, Rampillon, Reims, St. Maclou)—The Virgin's door—Local Saints and legends (St. John Baptist, Rouen; St. Stephen, St. Théophile, Paris; St. Thomas, Semur; St. Nicaise, Reims)—The Arts, Virtues and Vices—The Months and Daily Life (Paris, Amiens, Rouen)—Statuary (St. Stephen, Sens—The Virgin, Paris—Chartres, N. and S. porches)—Reims, W. portals—Figures of Christ (Chartres, Amiens, Reims, Troyes, Solesmes).

The lectures will be illustrated by lantern-slides.

Edward A. Reeves, F.R.A.S., Map Curator, Royal Geographical Society, "Surveying." Three Lectures.

March 27, April 3, 10.

MEETINGS FOR THE ENSUING WEEK.

Monday, February 21...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Fothergill Lecture.) Rev. G. H. West, "National and Historic Buildings in the War Zone: their Beauty and their Ruin." (Lecture III.)

Farmers' Club, at the Surveyors' Institution, 12, Great George-street, S.W., 4 p.m. Mr. C. Adeane, "Agriculture in the Devastated Districts of France and Belgium."

Economics and Political Science, London School of, Clare-market, W.C., 5 p.m. Hon. W. P. Reeves, "The Balkan States." (Lecture III.)

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m.

Geographical Society, Burlington-gardens, W., 8.30 p.m. Mr. A. P. Maudslay, "The Valley of Mexico."

Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Rev. A. H. T. Clarke, "The Fulfilment of Prophecy."

East India Association, Caxton Hall, Westminster, S.W., 4.15 p.m. Sir F. S. P. Lely, "A Forgotten Page in Indian History."

Tuesday, February 22...Illuminating Engineering Society, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Discussion on "Some Future Possibilities in the Design of Instruments for measuring Illumination (with special reference to Photometers depending on Physical and Chemical Methods)."

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. S. Sherrington, "Nerve Tone and Posture." (Lecture VI.)

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Mr. C. C. James, "The Main Drainage of Cairo."

Zoological Society, Regent's Park, N.W., 5.30 p.m. 1. Rev. H. N. Hutchinson, Exhibition of drawings of Extinct Animals. 2. Mr. R. I. Pocock, Exhibition to illustrate the structure of the Tympanic Bulla in Hyænas. 3. Mr. C. T. Regan, Lantern exhibition of the nest of a Fighting Fish and the climbing habits of a Catfish. 4. Mr. B. F. Cummings, "Studies on the Anoplura and Mallophaga, being a Report upon a Collection from the Society's Gardens." (Part I.) 5. Dr. P. Chalmers Mitchell, "Further Observations on the Intestinal Tract of Mammals."

Electrical Engineers, Institution of (Local Section), 17, Albert-square, Manchester, 7.30 p.m. Mr. E. V. Paunell, "Continuous Current Railway Motors."

Wednesday, February 23...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Miss H. B. Hanson, M.D., "Serbia as seen by a Red Cross Worker."

Geological Society, Burlington House, W., 8 p.m. Mr. H. Dewey, "On the Origin of some River-Gorges in Cornwall and Devon."

Electrical Engineers, Institution of (Local Section), The University, Birmingham, 7 p.m. Dr. C. Chree, "Terrestrial Magnetism."

Thursday, February 24...Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Child Study Society, at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W., 6 p.m. Mr. C. Burt, "Psychological Problems arising out of the War."

China and Japan Societies (Joint Meeting), Caxton Hall, Westminster, S.W., 3.30 p.m. Mr. Shinji Ishii, "The Island of Formosa and its Primitive Inhabitants."

Royal Institution, Albemarle-street, W., 3 p.m. Sir Frank Dyson, "Measurement of the Brightness of the Stars. Lecture III.—The Milky Way and the Magellanic Clouds."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m.

Friday, February 25...Royal Institution, Albemarle-street, W., 5.30 p.m. Professor Sir A. Quiller-Couch, "The Commerce of Thought."

Engineers and Shipbuilders, North-East Coast Institution of, Newcastle-on-Tyne, 7.30 p.m.

Economics and Political Science, London School of, Clare-market, W.C., 5 p.m. Professor W. G. S. Adams, "The Agricultural Resources of the Empire."

University of London, Bedford College, York Gate, Regent's Park, N.W., 5 p.m. Mr. A. D. Lindsay, "The International Crisis: the State and Society."

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

Saturday, February 26...Royal Institution, Albemarle-street, W., 3 p.m. Hon. J. W. Fortescue, "Eminent Generals of the last Great War. Lecture II.—Sir John Moore."

Journal of the Royal Society of Arts.

No. 3,301. VOL. LXIV.

FRIDAY, FEBRUARY 25, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, MARCH 1st, 4.30 p.m. (Ordinary Meeting.) CHARLES DELCHEVALERIE, "Maeterlinck, Verhaeren et les Lettres belges" (in French). GEORGE GRANVILLE LEVESON-GOWER will preside.

Further particulars of the Society's meetings will be found at the end of this number.

INDIAN SECTION.

Thursday afternoon, February 17th, at 4.30 p.m.; LIEUT.-COLONEL SIR DAVID W. K. BARR, K.C.S.I., in the chair. A paper on "The Saints of Pandharpur: the Dawn of the Maratha Power," was read by Mr. C. A. KINCAID, C.V.O., I.C.S., author of "Deccan Nursery Tales," "The Indian Heroes," etc..

The paper and discussion will be published in a subsequent number of the *Journal.*

FOTHERGILL LECTURE.

On Monday afternoon, February 21st, the REV. DR. HERBERT WEST, D.D., A.R.I.B.A., author of "Gothic Architecture in England and France," delivered the third and final lecture of his course on "National and Historic Buildings in the War Zone: their Beauty and their Ruin."

On the motion of the CHAIRMAN, a vote of thanks was accorded to the Rev. Dr. Herbert West for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

PROCEEDINGS OF THE SOCIETY.

ELEVENTH ORDINARY MEETING.

Wednesday, February 23rd, 1916; SIR FRANCIS CHARLES GORE, K.C.B., Hon. Treasurer to the Serbian Relief Fund, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Jeejeebhoy, Merwanjee D. M., 78, Apollo-street, Fort, Bombay, India.

Mukerji, B. K., Lashkar, Gwalior, India.

Oliphant, Professor Samuel Grant, A.M., Ph.D., Grove City College, Grove City, Pennsylvania, U.S.A.

The following candidates were balloted for and duly elected Fellows of the Society:—

Anderson, Frank Bartow, The Bank of California, San Francisco, California, U.S.A.

Dhari, Alakh, Oudh Commercial Bank, Limited, Fyzabad, India.

Farman, John, "Kirkholme," 16, St. James'-avenue, Beckenham, Kent.

Lall, P. C., Purnea City, Behar, India.

THE CHAIRMAN, in introducing the author, said that Miss Hanson was an assistant medical officer of the London County Council. At the beginning of the war she went with Mrs. Stobart to Antwerp, and was there during a great part of the siege. In March last she went out to Serbia, where she remained for five months in two hospitals in that country. She was then recalled by the London County Council to take up her duties in London. It was her experiences and adventures during her stay in Serbia that she gave in the paper.

The paper read was—

SERBIA AS SEEN BY A RED CROSS WORKER.

By MISS H. B. HANSON, M.D., B.S., D.P.H.

My time in Serbia unfortunately came to an end last August, owing to my being summoned home by the London County Council, so that I missed all the recent fighting and did not share in the adventurous trek which so many members of the various units took through Montenegro and Albania.

I had altogether six months in the country. From the beginning of the war I had worked with Mrs. Stobart's unit first in Antwerp, where we went through the bombardment, and then at Cherbourg. In February, 1915, as the number

of wounded in the latter town began getting fewer, Mrs. Stobart and many of the unit decided to come on to Serbia. They went across to England to collect stores while I came straight through *viâ* Italy and Greece, and, owing to delay in obtaining Government transport, they did not reach Serbia till the end of April, whereas I arrived in the beginning of March. I spent the two intervening months working in the Scotch Mission in Kragujevatz. This was the first of four units sent out by the Scotch federation of Women's Suffrage societies, which same body, having collected now some £80,000 besides numerous stores, has equipped also two women's hospitals for France. In every case the doctors of the unit were women, and so were nearly all the remainder of the staff. In Kragujevatz, for instance, the treasurer and a mechanic alone were men.

This unit had arrived in Kragujevatz at the beginning of the year, and had had a very uphill time. Fighting had not taken place since November, but during that month the Austrians had approached close to Kragujevatz, and the place had consequently been evacuated. For some time after their arrival, therefore, it was impossible to obtain any household utensils, and until their own stores were unpacked they had even some difficulty with food. They could not at once make their own feeding arrangements, as the stove they had brought out was so badly packed that it fell to pieces. Unpacking was done in the courtyard, and, as soon after their arrival heavy snow fell, the unit were engaged all one day grubbing for bits of stove in the snow. Even after being put together it always refused to cook a roast. So for the first few days they snatched a hasty breakfast of hot water and biscuit standing round a table, and for their midday meal they resorted to the one hotel in the place that had kept open. Unfortunately the hotel was not able to keep up to time in its arrangements, so that it sometimes occurred that the first batch of sisters who came off duty had to return to hospital to relieve the others before they had succeeded in getting any dinner at all themselves. There remained for some time shortage of various articles of food in the town, so that occasionally on buying cakes one found they had been made without sugar, and on one occasion, when a consignment of sugar had come up from Salonica, a crowd of some 300 persons gathered round the grocer's shop. At another time, too, salt ran out, and we were offered a keg of butter in exchange for a sixpenny bar of salt.

There was always a plentiful supply of meat, milk and eggs. At first there was only obtainable a rather coarse brown bread, and we were completely without butter for about two months, for Serbian butter we did not eat for fear of infection, and our own supplies had been mislaid at Malta. A similar disaster befell our tea. Sir Thomas Lipton, on one of his visits, kindly promised to supply this deficiency, and great disgust was felt when week after week went by and no tea arrived. At last, however, it was discovered that the precious chest had been by mistake taken by the orderlies into the matron's room to serve as a dressing-table. As regards meat there was more than enough, but there was a certain sameness about it. Pig formed our staple diet. From time to time it was varied by lamb, chickens, or turkeys, and it would, perhaps, have been varied more often had it not been for the fact that the animals for consumption generally came up alive, and after, for instance, a little kid had been made a plaything of for several days, or a woolly lamb had wandered round with blue ribbon and a bell, it went against our hearts to slay and eat them. It is, however, remarkable in how many ways pig can be cooked, and it was disguised all the more readily as the Serbians (and we employed a very good Serbian woman cook) do not joint their meat in an English manner. Pig stew, pig hash, pig joint, pig chop, and pig soup were served daily, and it was frequently the case that it was not till one was half through one's meal that a certain familiarity of flavour made one realise that one was once again consuming pork. At breakfast pig was also eaten under the courtesy title of bacon. One real drawback in the earlier part of the year was a lack of fresh vegetables. Still, there was an endless supply of prunes, and after eating these as a vegetable we quite contentedly ate them again with rice or custard as pudding. We had also, in default again of our own stores, nothing but eternal Serbian prune jam; altogether there was at times rather a sameness about the diet which led one of our numbers to comment on the brilliancy of our cook, who first, like any common or garden person, divided the week into seven days, and then carefully provided exactly the same menu for each day.

The house in which the Scotch unit was established was a very large roomy one that had at one time belonged to the Crown Prince. It was not, however, very suitable for a unit of forty-odd people, as it consisted of a number of big rooms which had to be used as dormitories for

eight or nine people each, nor was there any small room which we could portion off as a bathroom. Eventually we erected one with walls made of old bits of wood in the courtyard, and with an apple-tree bough for roof, the smaller branches of which acted as pegs, but in the earlier part of the year, with snow on the ground, this would have been useless.

On arriving in the town the Scotch unit had taken over a surgical hospital of some 200 beds, and at first their work was very arduous, as the Serbians had been unable to cope with the tremendous number of patients, and not only was the hospital (an old school), in common with all others, very overcrowded, but the wounds of the men were in a very septic condition. After a few weeks work, however, things began to arrange themselves satisfactorily. The convalescent patients had been drafted out, the hospital had been reduced to a state of order and comfort, so that, as one of the members of the Royal Army Medical Corps said, "You might as well be at home as be here," and a second commodious house had been assigned to the unit as a dwelling-place, when suddenly typhus, that had been left behind as a legacy by the retreating Austrian army, began spreading like wildfire over the country. Even at Salonica the moment one entered the train one realised that something unusual was afoot. The carriages were so strongly impregnated with formalin that one had to rush to the window and throw it up before one could breathe. Arrived on Serbian territory, we found the nature of the disinfectant changed, but it was even more in evidence. At the bigger stations in came a man with a keg of disinfectant on his back, which he proceeded to squirt impartially over one's compartment, one's baggage and oneself. At other stations, small boys would be found selling camphor or naphthaline, rather than food or papers, and indeed the people who came in and out of the carriage smelt strongly of these two things, and would drop pieces out of their pockets, skirts or bags as they moved. At that time, too, the Serbians could not afford oil to light their carriages, and a rather shabby appearance was consequently given to them by the splashes of grease that were strewn all over window, rack, cushions, and floor, from the candles that the passengers travelled with.

When we arrived in Kragujevatz itself, we found almost a plague-stricken city. The Serbians hang out a black flag from the house where a death has occurred, and thus in a very graphic manner the ravages of typhus were displayed. It was nothing to meet several funerals in a short walk, and since the Scotch dwelling-house was opposite the Cathedral, we used to hear the bells tolling nearly all day. No longer were funeral services allowed to be held in the Cathedral for fear of infection; but the bell tolled as the procession swept by.

If the large number of wounded had proved too great for the Serbians to handle, it can be imagined what the condition of affairs was like when the number of patients in the army was tripled by the incursions of typhus. Besides which it must be remembered that many medical men contracted the disease, while the activities of the ordinary population were crippled in a like manner. All the available buildings in Kragujevatz were laid under toll to provide room for the sick and wounded—schools, colleges, large houses, "gast-houses" (a sort of small restaurant), and even stables and cowsheds. One of these cowsheds, when cemented and properly fitted up by the "Wounded Allies," made a delightful hospital; and before its transformation its troughs had served for orderlies to sleep in. In their treatment of Austrian prisoners—the *fons et origo* of all the trouble—the Serbians never showed any less concern than for their own men. If the one suffered hardships owing to lack of space, attention and medical appliances, so did the other. I could never find any difference made between them; in fact, among our patients one was at first almost unaware which was Austrian and which was Serbian, but of the two the latter naturally succumbed more easily and a separate burying ground had soon to be set apart for them. Here it was impossible to dig separate graves; shallow pits were made, and the heavy rains of the spring and the heat of the summer made the cemetery at one time a very unpleasant place to visit. Despite this, a little wooden cross was erected with the name of the deceased, and after a few weeks a veritable forest of these covered the hillside. Just as they were unable to dig separate graves, so they were unable to provide separate coffins for the prisoners, and a number of bodies were placed together in a cart to be removed to the cemetery. The carts were hastily put together, and sometimes even between the crevices could be seen portions of human limbs.

Coming up from Salonica, one of the Scotch sisters, in spending a day at Nish, had been taken over a Serbian hospital. The director showed her all his arrangements, but displayed with especial pride and complacency a batch of

coffins in the corner. Of these he had been at first short; hence his delight at the large quantities now in stock; but it was not a reassuring spectacle for a new arrival in the country.

The shortness of space to place the patients in was rivalled by the shortness of the beds to lay them on. Many men slept on the floor. In some cases three shared two beds, or two one. The beds themselves were of the roughest make, and consisted generally of three planks on wooden trestles, with a straw mattress. These beds were particularly unsuitable for typhus patients, as during their delirium they frequently kicked the planks apart, and bed and patient together came clattering to the floor. There was also a great dearth of covering for the men. In one case, a patient had been two or three months in a Serbian hospital, and when he came into ours we found that he had lain so long curled up for warmth that for some days it was impossible for him to straighten out. Even means of transit were inadequate. On one occasion seven patients arrived at the hospital huddled together in an ox waggon, one of whom was already violently delirious. Other necessaries were lacking too; at one time, we ourselves, owing to a month's delay of baggage at Malta, were reduced for a few days to one thermometer for the whole hospital, and that the private property of one of the sisters. In Kragujevatz we were fortunate in having a fairly good supply of firing, though in exceptionally cold weather, when snow was on the ground, and when in consequence more than usual had been used during the day-time, we found sometimes at night that we had only enough wood for one fire, or at most a couple, in the whole hospital.

As regards food, there was a plentiful supply. The coarse brown bread was the staple food, and of this the men were very fond. They were allowed a certain ration every day, and in the surgical hospital sometimes sold what they did not want to visitors, outside the windows—in the early days after evacuation the people were glad to get it. Another frequent food was hard-boiled eggs, and these two articles lent themselves well to the men's custom of keeping their eatables under their pillows. Stews and soups, milk and rice pudding could not be satisfactorily disposed of thus, though on one occasion, after a feast day and a visit from friends, one patient was found with a whole roast sucking-pig under his pillow. This dainty he was to gnaw at intervals. On another occasion, in another hospital where I was working, we were surprised to find that one man always produced for cooking a fresh egg every day. This particular hospital was surrounded by a garden, and after a while we discovered that the man had enticed a hen into his bed.

In the earlier part of the year, when the patients consisted almost entirely of wounded men, and not of people suffering from typhus or other severe diseases, the attention they received from doctors and orderlies was not so strikingly inadequate; between English and Serbian medicine there is not much to choose. But of nursing as known in England there was, as in many other European countries, a complete absence; and since, as anyone with the most elementary knowledge of illness is aware, the nurse is always the better half of the doctor, the sufferings of the men when desperately ill and unable to help themselves can be more easily imagined than described.

Typhus is a disease that runs through fairly regular stages, and as—when the Scotch unit took over a second hospital—we cleared out gradually ward by ward of mixed diseases to put in typhus alone (sometimes as many as thirty-five patients a day, the full ward complement), we got a very good picture of the course it ran. The terrible mortality, in places 80 per cent., that occurred in February, owing to the hugeness of the epidemic and the consequent inability of the country to deal with it, fell with quite a moderate amount of nursing and care to about 10 per cent. For the first few days the patients for the most part did not seem acutely ill, but on about the fifth day the pulse would begin to cause anxiety, and while for some hours it would appear good, a chief characteristic was that suddenly it would almost vanish. At about the ninth or tenth day, in the large majority of cases, delirium set in, and the procession by night going round the bare ward, an orderly carrying one little lantern, was a very weird sight. On all sides men were tossing in their beds and gibbering and chattering like monkeys. Then, after a few days, the delirium got less, and suddenly one morning one would go in to find the men sitting up as one entered and clamouring for food. They could not wait till one got round, but, pointing to their mouths, called out from the other end of the ward, demanding soup and wine and a double portion of bread and chicken. Fortunately in this disease, unlike typhoid, one was able to accede to their requests. In a few cases, and these seldom recovered, the acute active delirium subsided, not into consciousness and recovery, but into an inert and passive

form in which the patient muttered and moved his fingers incessantly. It was the similarity of this stage of the disease to the delirium of enteric fever that gave the latter its designation "typhoid." In badly-nursed, ill-nourished cases, various complications such as gangrene and subacute inflammations arose; but in our hospital we saw little of these things. It was a consolation to find that the members of the Scotch unit who suffered from typhus, said that it was a comparatively painless disease, and those that had tried both, further volunteered that it compared very favourably with typhoid. As doubtless you all know, typhus is conveyed by the bite of a small animal, named "pediculus"—if one could keep free from bites one kept free from typhus. For safety, the Serbians relied a good deal on ordinary disinfectants, and also on garments that did not permit the entry of anything noxious. Each hospital in Serbia has a "director," who sees to various technical points, such as discharge, etc., and in our case the director took his midday meal in hospital, together with the dispenser and one or two clerks. They were kind enough to give us a general invitation to join, and as our house was some twenty minutes off we sometimes went. The meal began with a very interesting ceremony; methylated spirit was poured into each plate, set fire to, and then fork, knife, spoon and bread were passed through the flame. We relied chiefly on costume for protection. We intended wearing one-piece batiste garments fastened up the front and round the neck, but as the batiste did not arrive we had to take the bottom part of the pyjamas from our stores and wear that. Over this came an overall, of various sorts and shapes, some white, some grey, some fastened behind and some in front. Riding boots came nearly to our knees; these we bound round with muslin sprinkled with camphor oil or naphthaline. Our necks and sleeves were tied with the same sort of bandage, and our heads enveloped in muslin similarly scented. I may say that altogether it has never fallen to my lot in any time or place to see such an appalling collection of human beings. Years hence, legends will probably arise in Serbia of monsters, hideous in shape and form, who appeared at the time of the Great War, who scourged the already decimated Serbians with a virulent plague of typhus, and who still further tormented their victims with strange drugs, obnoxious food, copious ablutions and blasts of fresh air. It is impossible to give any reliable statistics of deaths; notification of the disease and of death were unknown. Even as regards the Army I never succeeded in getting any reliable figures. Only those dealing with the medical profession can I at all vouch for; here the number of people who succumbed rose steadily from units to tens, and tens till it got beyond a hundred. Altogether practically one-fourth of the Serbian doctors died. In our own unit we also had our victims; eight members had the disease and three died, amongst them an orderly, Miss Neil Fraser, the well-known golfer. Five sisters contracted it, two of whom died; while two doctors had it and recovered. No one could have been more kind than the Serbs when these calamities occurred, nor shown more genuine sorrow. I arrived in Kragujevatz the day the first funeral had taken place, and I sat up part of my second night with Miss Fraser. Two days later I attended her funeral. The service was in Serbian and conducted according to the rites of the Eastern Church and with full military honours. A representative of the Crown Prince was present, and the Serbians, amongst others, sent beautiful wreaths. The service took place outside the military barracks; the sky was grey and snow was on the ground, but the priests, with their brilliant velvet robes embroidered in gold and silver, the candles, and, above all, the music, rendered it a most impressive ceremony. The priests came up in ordinary garments, black robes and black felt hats, and proceeded to change in the open. During the whole service in their left hand they held a lighted yellow taper which they protected from the wind with their hats. One of those officiating carried a censor, and from time to time censed the coffin and the congregation; but it was the music that made the deepest impression. The service was almost entirely choral. Sometimes one priest alone, sometimes all together, intoned, and then the choir, unsurpliced, broke in suddenly with the responses in a sort of deep Gregorian chant, very wonderful and effective. The whole thing was poignant to a degree—plangent, appealing, and almost weird; incomparable with anything I have ever heard before in solemnity, beauty, pathos, and even tragedy. The service lasted some three-quarters of an hour, and after it was over a procession formed to walk the mile and a half to the cemetery. First came six boys in red-and-gold surplices, the first carrying a white cross engraved with the name of the deceased, the rest bearing aloft large gilt stars adorned with multitudinous rays. Then came the clergy, the military band (the Crown Prince's, the best in Serbia, in grey

uniform), then a gold cross, then the hearse, then the military attachés, the unit (in their grey uniform), and behind several well-known townspeople and various friends. The mud was inches deep, and plunging along, behind the swaying hearse, to the accompaniment of the magnificent funeral march, was an experience never to be forgotten. I walked with a relative of the aide-de-camp of the Crown Prince, a charming girl who spoke broken English. She was terribly distressed by the fact that two deaths should have occurred, and kept on saying, amidst tears, how noble was the work the unit was doing; it was brave enough to risk one's life for one's own country, but for someone else's country it was wonderful. Another short service took place outside the cemetery and yet another inside, while at the end the English military attaché read a few English prayers over the grave.

Yet another funeral took place later from the Scotch unit, and after Mrs. Stobart had been out some weeks an epidemic of typhoid ran riot amongst us. Seventeen of our members contracted it, while three died. Amongst these latter, an irreparable loss both to her personal friends and to the world at large, was Mrs. Percy Dearmer. This illness was not considered so infectious as typhus, and we were allowed the use of the Cathedral for the funeral. Most graciously we were permitted to use the English Service in one instance, and the fact that an Anglican Service was being held in an Eastern church made a very unpretentious service an historic event. In Mrs. Dearmer's case the service was Eastern conducted in Serbian, and as the coffin was borne down the Cathedral steps an English-speaking Serb made a funeral oration, addressing the deceased and saying how she had lived *sans peur et sans reproche*, and died as bravely as any soldier. Emphasis was laid on these words by the fact that the authorities had sent up for her a hearse usually reserved for officers, on the top of which shone the upper half of a suit of armour, and they had sent also to burn beside her all the previous day a candle in a beautiful huge silver candlestick. The procession that followed her to the grave must have been nearly a quarter of a mile long.

It was the intention of the Serbians to gather together the bodies of the various members of the English units who had died in Serbia and place them in a mausoleum, the designing of which had already been begun by a well-known Serbian artist when the autumn fighting broke out.

When first the Stobart unit reached Kragujevatz, the Scotch unit was much infected with typhus, so hardly any of our unit were permitted to go to visit them. Later, when we were infected with typhoid and they were well most of their unit were not allowed near us, and the only interchange of courtesies for some months, therefore, seemed to be attending each other's funerals.

Great anxiety was felt throughout the country during the illness of Lady Paget, and prayers were continually said for her in all the churches; an equally striking, though more humble tribute was the way in which an old man, who had been paid weekly by one Scotch sister to look after the grave of another, asked, when the first sister went home, if he might continue to attend to it without reward until the day of his own death.

Other units suffered greatly from disease; typhus and typhoid both attacked several. Amongst Lady Paget's staff at Uskub, amongst other missions there, and amongst one of the Scotch missions which settled later in the north, several deaths occurred. One mission alone, situated at Vrnjatchka Banja—where most of the English units in the country were massed when taken captive—has for a whole year shown an absolutely clean bill of health as regards any serious complaints. That is the unit under Mr. Berry, the well-known "Royal Free" surgeon. In every way his was the most favourably situated mission in Serbia. Vrnjatchka Banja is itself a modern health resort, placed high up amongst exquisite mountain scenery, and his main hospital, "Terapia," was originally a sanatorium and boasted electric light, a water-supply, and baths too numerous to count.

Furthermore, nearer the town was a large villa which was used as a receiving house for patients, where they were watched for some days before finally being distributed to the various hospitals, so that disease could declare itself without giving rise to widespread infection, and finally a sulphur swimming-bath close at hand was utilised to bathe all the patients who were well enough before they entered the hospital. Mr. Berry also built a typhus barraque—a wooden shanty with tiled roof. This edifice, the pride of the mission, was the last word in sanitariness, picturesqueness and comfort. It cost £100, was erected in fourteen days, and accommodated forty people. However, in one villa, the "Mercur," before the unit arrived out, an interned Austrian woman had for some time been doing the best she could for a number of convalescent patients. This villa was handed

over to the Berry unit as far as surgical attention went; but the old lady still continued in charge and swept round the wards in a trailing velvet skirt, a sight to make one shudder. For some time she remained immune, and she hugely amused us one day by wondering how it was members of the English units became ill. Did we, she inquired, have our windows sufficiently open, or wash our hands before meals? Not long after, however, she caught the disease herself, and had to be nursed up at the typhus barraque.

Next a word or two as to our orderlies. These were chiefly Austrian prisoners, who on being trained did their work exceedingly well. The freedom accorded them was remarkable, and compares with nothing in this country. It was accounted for largely by the fact that many of them were Slav in race and sympathy, coming from just across the Save and Danube. There had been in the earlier Austrian invasions some terrible instances of "frightfulness," but in the later ones these did not take place, and there were various stories of wholesale desertion from the Austrian army. At Vrnjatchka Banja a man who undertook housemaid's duties on the strength of having been married fifteen years, was asked by a Serbian lady how he came to fight against his own race. "Well," he replied, "we fought for one day, but we gave ourselves up in the evening." On another occasion two Serbs saw four Austrians approaching, and feeling themselves outnumbered prepared to surrender. "For God's sake don't do that," cried the Austrians, "we have come to surrender to you." The Serbian villagers were in many cases very kind to the prisoners, distributing food amongst them, and it often happened that an Austrian was put in authority over Serbian patients of a higher martial grade than himself. The friendliness of the Austrian for the Serb, too, may be shown by the fact that never, as far as I know, did he abuse his liberty, and on such occasions as the Serbs cried out with the pain of their dressings, the orderlies would admonish them gravely with "You are no Serb." On one occasion a somewhat humorous incident occurred. We had a sentinel at the typhus hospital, and this man one midnight going for his meal left his gun lying in the hall. An Austrian orderly coming downstairs, clad in evening attire of cotton pyjamas and night socks, immediately seized upon it and strutted up and down the corridor with great glee. He gave it up immediately on the return of the sentry, but at least for some minutes the only armed person in a hospital containing one English sister and 200 sick men, was one of the enemy. I must here emphasize the pluck of the nurses, one of whom night after night remained alone on duty in this hospital at the end of a lonely road and twenty minutes' walk away from any English help.

At Vrnjatchka Banja the orderlies were selected by the two English missions from a number of prisoners drawn up at the roadside. The scene was much like a slave market, the difference being that the men from hungry, unkempt, disease-stricken beings, became in a short time very healthy specimens of humanity, instead of the other way about. They were treated like patients in the matter of washing and shaving, and on one occasion at Vrnjatchka Banja a strange contretemps occurred. They were conducted to the sulphur baths and their clothes removed, but by some mistake no fresh ones were supplied. In the late afternoon their non-appearance at the hospital occasioned some comment, and on a search being made the party was found at the bath-house, having been impregnated with sulphur fumes for some seven hours.

On another occasion a hitch was caused with patients at the bath-house. One or two showed unusual reluctance to go into the water, and it was put down to obstreporousness. It was suddenly discovered, however, that the baths not having been used for several days a thin layer of poisonous gas had collected on the top, and it was this to which the men were objecting. Austrians were not only used as helpers in the wards, but they also did the housework and waited at table. At one time the waiters at the Scotch unit presented a rather variegated appearance, as they wore the upper halves of the pyjamas whose lower portions we made use of in the typhus hospital. There were men of all sorts and types among them. Some were simple, like the one who said to a friend of mind speaking of the war, "You know it is not a bit what you would think; you might be killed any moment." He had evidently expected a simple punitive expedition, fraught with no danger. There were several men from London restaurants, "Carlton," "Savoy," etc., who spoke English perfectly. One of these was a waiter at an English club in Nish, and another was chef at one of the Scotch missions. One of the waiters at Lady Paget's was a distinguished Viennese professor, the man who saw after the "Scotch" washing was a lawyer, and the man who blacked our boots in camp was reputed to be a millionaire.

Not long after the arrival of the Scotch unit in Kragujevatz, an English Army Medical Corps commission came out, thirty strong. Their first work was to see to the cleaning up of the country, and for that purpose they introduced a number of very simple disinfectors. These consisted of barrels through which steam was passed. Other places, other manners, and I shall never forget the curious entertainment provided one afternoon at the Scotch hospital when the *élite* of the military and civilian world were invited to come and watch a test experiment as regards the effectiveness of the sterilisation. After some difficulty in our now clean hospital, one or two garments, not free from pellicular life, had been secured, and these, having been submitted to the steam test, were solemnly handed round to the guests to investigate whether the deed had really been done, or whether in the case of the pediculus, as in that of Mark Twain, "the report of my death had been greatly exaggerated." Full powers had been given to the head of the commission by both Serbian and English Governments, and the speed with which legislation was enacted was a lesson to this country. A modest bill would be taken by special courier to Nish to be made in half an hour into an Act of Parliament. In this way notification of typhus was obtained; for a month also traffic was stopped, a very necessary measure, for the soldiers travelling back and forth on leave had been steadily infecting the outlying districts. After this typhus work was finished, the commission ran a sanitary train, fitted up with sleeping accommodation for thestaff, baths, disinfectors, consulting-rooms, etc., and went north to inoculate the army against cholera. A still more numerous French commission, which came out later, inoculated the civil population against the same disease, and also against diphtheria and small-pox, and it was doubtless owing to all this work that cholera—that worst scourge of all, compared with which typhus and plague are simple megrims—did not make its appearance in Serbia.

Besides these two, a strong American sanitary commission came out and worked rather further south. There were also several admirable American medical units, and in addition to the ten or twelve British, Danish and Dutch workers also arrived in the spring. Altogether when Mrs. Stobart reached Serbia at the end of April the country presented a very different appearance from earlier in the year. Typhus was no longer a pestilence that walked in darkness, and the vast majority of those soldiers who were still not quite recovered from their wounds were thoroughly convalescent. Mrs. Stobart offered the services of the unit for either typhus or surgical work, and the authorities chose the latter, giving us for a site a piece of high common ground out of the town, beyond the military barracks, from whence all round one could see an encircling belt of hills. We were entirely a field hospital, and our equipment of some sixty tents we erected and got ready for our patients within a week. We had accommodation for 130 men, but only a few days elapsed before we realised that our unit of forty-nine could not possibly occupy itself with only that number of patients, and while meditating on this point Mrs. Stobart had the brilliant inspiration of starting a number of wayside dispensaries between Kragujevatz (the military headquarters) and Belgrade. The civilian population was entirely without help. It was riddled with infectious diseases, and, apart from the sadness of its own plight, its condition was of grave military import as there were at that time continual rumours of advance, and the army was liable to get infected as it went north. Accordingly a small tent was put up on the road behind the camp, and more were to be erected as soon as further equipment could be got out from home. Meantime, two of the doctors, with a view of long quiet spells for learning the language, offered indefinitely to sit down there in state, beside attending to their own wards. The first day no patients arrived, and the languages proceeded admirably; the second day twelve came, rather a surprising number; the third day there were over thirty. This was disconcerting and the language was not touched; the fourth day there were over fifty, and soon after the week was out the number registered 150. By this time the work was hastily re-arranged, for 150 patients in a small tent, with an almost tropical sun, and when all the business has to be done through an interpreter, means a full day's work for two people. The patients came from distances of even forty miles, walking or riding in bullock carts and leaving home often at midnight. We found we were striking virgin soil; typhus came up that, thanks to the new legislation, we could notify and send forcibly into the town, typhoid, a good deal of scarlet fever, some small-pox and a great deal of diphtheria. This last was of a most virulent type, and it was amazing that children so badly infected could walk such miles to come and see us without succumbing to heart failure. In addition, there were many septic injuries, for the

prevailing ideas of how to dress wounds were primitive. Sometimes coffee grounds, sometimes tobacco leaves, would be plastered on a scald or burn, and on one occasion a curious appearance of very black gangrene turned out to be due to the painting on of ink. We found much indigestion, especially among men, a fact which did not bear out the contention of one optimistic old peasant lady, who said that: "Ah! you have beautiful food, and we eat only bread and a few onions, but we can fill our stomachs with green apples and be none the worse, whereas you would suffer much pain." We had various other complaints to treat, and at least one baby was born in camp and duly christened "Stobart." The patients were supposed to bring their own bottles, and a curious assortment came up; wine and beer bottles belonging to the country, of course, but also chloroform drop bottles, babies' bottles, and bottles of eau-de-cologne, though where they obtained these it would be difficult to say. Altogether, in the first three months we saw 5,000 patients, and when at the end of July six other dispensaries came into being, the number increased rapdily, and at the time fighting began again, 16,000 had passed through our hands. We had not been working long, however, before we found that to pretend to treat the patients without a civil hospital at our backs would be a farce. For the men we obtained permission to use the soldiers' wards, and for the women we erected another tent. Our first woman patient was a young girl of fourteen, who had to have her leg amputated for gangrene after typhus. She made a rapid recovery, and became the friend of all the camp, hobbling round on crutches. She was also invaluable in the ward, as she knew where anything and everything was kept, and our many changes of sister, consequent on the illness of the staff, made this trait a very valuable asset. Of military work in the Stobart camp there is not much of interest to record, as most of our cases were so convalescent. The men were very kind to each other, and took a great interest in each other's operations. They were very plucky, and frequently when they were being dressed would tell one it did not hurt, and urge one to be more vigorous. They appeared to have little dislike of operations, and occasionally even threatening to do them themselves when we disagreed with their desire for incisions; but they did dislike anæsthetics. They often begged for operations without chloroform, and though on some occasions their objections broke down when the actual operation was in progress, on other occasions they went right through. One man who underwent a small operation under a rather inadequate local anæsthetic, could not sufficiently compliment the doctor on having done it, while a really touching case occurred up at Vrnjatchka Banja. Mr. Berry had to remove several pieces of dead bone from the inside of a man's jaw, a very painful process, as he explained. Yet the man persisted in refusing chloroform, saying he had been through the last war, and thought he could stand the suffering involved. This was evidently very severe, as he flushed up and tears came into his eyes; but each time Mr. Berry removed a piece of bone the man, as soon as he recovered enough to speak, patted him affectionately on the shoulder, and said "Dobra doctor," *i.e.*, "Good doctor."

The number of wounded was reported to be under 3,000 by August, and as the work of the units was getting very light many felt it was unfair to stay on in the country, especially as the Serbs were most generous to their guests. However, the authorities were most anxious we should stay, as they said there was bound to be fighting eventually. Up till October we had only one or two experiences of "recently wounded." On June 9th at 5 a.m., just as we were rising (we breakfasted at the early hour of six o'clock), we heard what was to some of us the familiar sound of loud explosions, and looking out of our tents we saw two German aeroplanes overhead. Our camp was in the direct line between Belgrade and the town with its arsenal, and a few yards only from the wireless station. The aeroplanes made for the town and dropped bombs there, first aiming at the arsenal, the Crown Prince's house, the Cathedral, etc., and then as they passed back they dropped any remainder near us, to show us we were not forgotten. Whether they aimed at us or not it was impossible to say; but since our Red Cross flag clung coyly to our pole the whole while, there is no reason why they should not have imagined us a military camp. A few minutes after the two first aeroplanes disappeared a third arrived, and this deposited one bomb quite close to camp, sprinkling the outside of some of our tents. We were hurrying down to collect fragments (we succeeded in piecing together nearly the whole of one bomb, time-piece, handle, etc.), when we saw a woman lying on the ground. This proved to be a poor villager, whose husband had already been taken prisoner and whose two sons were at the war, who had been going into Kragujevatz from a distant hamlet to shop. She was very severely

wounded, her right humerus was broken in several places, and the soft tissues pulped. A piece of shell had also penetrated the lung. We got her into the theatre in a few minutes, and did what we could for her, and while we were operating the Serbian director of the hospital came up and remarked on how bad she looked. We inquired as to the extent of damage caused by the raid. He replied that five people had been killed and eighteen wounded, a few beasts were reported decapitated in the market place; but no building of any importance had been damaged. The report of the raid in the German papers that one afterwards saw, gave, however, a lurid account of a burning arsenal and a town in flames. Later in the day the director again came up, and we asked for further particulars of injuries. He gave us the total of six dead and seventeen injured. We asked him who it was that had succumbed since the morning, and he replied, "Oh! I am counting your woman." We laughed and said our woman was doing exceedingly well. For a day or two she had a little pain and temperature, but was soon up and about and able to go home, the piece of shell still inside her chest. No one perhaps was more surprised than ourselves at her remarkable progress. In Antwerp the men had at least lain some hours in the trenches, and had jolted over long rough roads before they reached us, while at Cherbourg they had had two days by land and sea, with practically only a first-aid dressing, before they could be got into hospital; so that in each case some sepsis was present. Moreover, the soil in France and Belgium is much more highly cultivated and infected with more dangerous germs than that of Serbia, so that the men had not had a fair chance. But given an opportunity of attending to the patient within a few minutes of the infliction of the wound, then one finds that Nature makes light of shrapnel and shell, and sets about repairing even terrible injuries with amazing resource and energy.

We had two more raids before we had to evacuate Kragujevatz. In one case one of the aeroplanes was hit and fell, a long sheet of flame behind it. In the other, one shell fell close to our linen tent but did not explode, and the other fell on some barracks near. These were new buildings, destined for our winter headquarters, and we had already had patients in them; but fortunately they were empty at the time but for the storage of tents and marmalade. This latter the cook had remorselessly hidden away as our stores were not arriving properly from home, and she did not wish to be left without any delicacies at Christmas. It was now scattered in a sticky tinny mess all over the field, and we mourned what we had lost. On the occasions of these raids we had no anxiety as regards the patients, as there was always long enough warning to evacuate camp before we ourselves were bombarded. Either we had news that an enemy raid was expected, or since the aeroplanes always devoted their first bombs to the town, we had the necessary quarter of an hour in which to get our patients a few minutes up the road into safety. Our cavalcade was a delight to the eye. Derry and Tom's had presented us, by request, with two carts, and these, after being adapted for bullock traction had been decorating the end of our camping ground for some weeks. We had also a fleet of five or six motors, amongst others, a fine car presented by the Harvard students, labelled American Red Cross Humanity and Neutrality. The motors, as their nature is, at first refused to move, and the carts with their loads of men in brightly coloured dressing-gowns and pyjamas were well up the road long before the lorries could be got to work. The patients seemed to like their joy-rides, and the subsequent picnics up in the wood; in fact, they seemed to regard their whole time in camp as a great jest. They were very much at home strolling about our grounds, and Mrs. Stobart they called "Mother." The alteration in their looks as they got better was marvellous. On one occasion I made several attempts to locate an old man who had come into the Scotch hospital with a very severe thigh wound, whom I had not seen for some weeks. I asked several times in which ward he was, and though always told the same number I could never identify him. Eventually I found that the six weeks had changed a decrepit old man of sixty into a handsome youth of twenty-five, and he was simply unrecognisable. We had one man in camp who had come because he refused to stay in a Serbian hospital. He had originally been with the Scotch unit, but as he repeatedly refused the very simple but necessary treatment they advised, he had been removed to military headquarters. After a few days, however, he found he could not get on without English sisters to nurse him, and so he demanded to be transferred to us.

Patients who had been a long while in the Scotch hospital sometimes came up to us to finish their cure in our more airy establishment, and great was their joy when they recognised

their old sisters and doctors amongst the visitors. The day begins early in Serbia, and it was by no means always five o'clock before peasants taking cattle into market were to be found *peering* into our tents. Mrs. Stobart was generally on the spot before this hour; but history relates that even on one occasion she was caught "napping." Sunday was our field day, when streams of townspeople came up to inspect us. The camp was certainly on a beautiful spot, and at no time of day or night, whether in sun or in rain, did the surroundings fail to be exquisite. Yet we were in by no means the prettiest part of Serbia. Sometimes the camp itself looked entrancing. Under a brilliant moon the dead-white tents with the little ruddy lights gleaming inside made a perfect picture. Serbia is certainly very beautiful. Approaching it from Greece one finds, first, bold desolate country with huge grey boulders and crags. The villages are desolate and dirty; an appearance which is produced, it is reported, by the fact that the Turks, whose dominion over the country ceased only in the latter half of last century, did not suffer the Christian population to whitewash their houses. But even in the wildest parts appeared early in March the delicate pink blossom of the almond tree. Beyond Nish, the country became well wooded and well cultivated, and a little later in the year the land was a sea of fruit blossom; the vivid pink of the peach blossom especially beautified everything with which it came in contact. Sometimes this was a mass of yellow waters, for the spring rains were torrential. Against the ruthlessness of the floods the Serbians have protected their hay by placing the stacks amidst the branches of trees, so that it is not uncommon to see, reaching out of the floods, a slim brown trunk on which rests a conical heap of grass, with young green branches projecting from top and sides, like the holly on a Christmas pudding. The rains indeed and the climate generally were such that one resolved never to complain of the English climate again. If our weather consists of travellers' samples, theirs consists of bargain sale remnants. A day or two of snow occurs at frequent intervals in the winter, while in between fires are sometimes hardly necessary. The latitude is about that of Marseilles, so that the sun is fairly powerful, and as the country is surrounded by huge masses of land the difference between night and day temperature is considerable. Under canvas in May the heat seemed almost tropical, and we wondered how we should fare later on; but it never became unbearable, for in June and July there were terrific storms, lasting sometimes a whole night. First the thunder would roll over camp, then it would be deflected to the distant hills, complete part of a circle there, and return over camp again. Then once more it would depart, and one could watch the distant lightning, sheets of fire, or violet pink and golden forks. Rain would simply be tipped out of the sky at the same time, and huge gales would blow down our tents and break our poles. The worst wind storm we had, however, was fortunately unaccompanied by rain, and it occurred mercifully in the daylight. At a few moments' notice a tornado swept through the camp, overthrowing seventeen tents; amongst them, two where members of our own unit were lying desperately ill with typhoid. Had this been a usual night storm, accompanied by rain, one or two must inevitably have died; as it was, no very serious harm ensued. But at night the camp took on the appearance of an ancient herding ground, where the ghostly forms of prehistoric monsters, white, brown and grey, were seen squatting on their haunches or lying motionlessly at their ease.

It was on this unique occasion when the mess tent and the stores tents were blown down, when the kitchen fires were extinguished, when we were reduced to an evening meal of doubtful quantity and quality, eaten almost in darkness, in a shelter formed by branches of trees, that several Serbian visitors came up to see how we had fared. It was always a point of honour in camp to offer hospitality to visitors, and they were asked, as a matter of course, to remain to dinner. On their refusing, Mrs. Stobart asked in pained surprise, "But you don't consider us disorganised, do you?"

This frequent rain and ensuing mud led our camp costume to be of a highly heterogeneous order. Some of the unit frankly wore riding breeches and leggings; others wore skirts shortened to the knee, even the orthodox nurses were reduced to Wellingtons and overalls belted up round the waist, or men's shirts treated in the same way. In the hotter weather, too, their immaculate collars and high dresses gave way to garments very open at the neck, caps turned into huge panamas or pith helmets, while at other times sunbonnets, waterproof hats, simple kerchiefs or the orthodox black silk hats of the unit were worn. We were a motley crew and must have served to deepen in the mind of the Serb the extraordinary impression of English women already created by the typhus unit. But the camp mud never quite equalled

what we had seen in connection with the typhus hospital. That building lay some way out of the town, and we had to go backwards and forwards a good deal in the dark. Riding boots hardly kept us clean, and at the hospital gate stood a man, not with anything so ordinary as a brush to remove the mud, but with a simple bucket of water to wash us down. One day going along, I discovered a man in mid-air, walking high and dry in the middle of the road. Wondering if the miracle would be repeated in my case, I tried the experiment also, whereupon I found a series of bricks had been laid down on which, if one could keep one's balance, one could walk as on stepping-stones. Even in the town at the time when the snow on the hills was melting, broad streams ran down each side of the cobbled street, and one often had to walk yards before one could find a narrow enough place to cross. We had one entertaining experience as regards mud in a motor-car. Mr. Berry, with whom I was then staying, had to come over to Kragujevatz to do an operation, and as it took over a day to compass the forty-four miles by train he decided to risk coming by car. The first fifteen miles was accomplished easily, then about three o'clock we stuck and had to be dragged out by some peasants; the second time we needed four oxen to assist us, and the third time six oxen took an hour to extricate us with the engine working as well. It was then getting dark and we were twelve miles from Kragujevatz, and as the houses were liable to be infected there was nothing for it but to spend the night in the open. Fortunately, Mr. and Mrs. Berry had sleeping bags, so, buying a little hay, they lay out in the driest place in the middle of the road. Unluckily I had no bag, so I was ignominiously relegated to the interior of the car, while the driver slept in front. There was frost in the night, and by eight next morning when we reached Kragujevatz we were decidedly cold and hungry. These roads had stood the Serbians in very good stead during the last invasion; the Austrians had been unable to drag their heavy guns along, and had left behind in their retreat large stores of equipment. Nothing more impressed on the mind the greatness of the Serbian victory in 1914 than a visit to the Kragujevatz arsenal, where numbers of huge sheds were completely filled by Austrian military apparatus. In the summer the mud was replaced by dust. As one motored along, no trace of road was visible behind, only at intervals just a head of a horse or cow could be seen coming out of the swirling clouds.

These were, however, minor matters. The flowers in the woods in the spring were exquisite. In the summer we trod daily under foot in the camp a variety of most dainty blossoms, while of all the summer wild flowers, perhaps the masses of yellow iris that grew in the fields were the most striking. The Serbians did not, however, leave us only wild flowers to admire; they erected in front of each dwelling-tent a little plot of raised ground wherein roses and other things grew. Mrs. Stobart had a similar little vegetable garden at the back of her tent; it gave an appearance of permanency in our nomadic life, as each garden looked uncommonly like a grave ready for the owner to tumble into should need arise. The Serbians also erected for us several huge shelters, formed of branches of trees, supported on a wooden framework. These remained delightfully cool when canvas was almost unbearable, and were invaluable in wind storms when our tents were demolished. They were put up, I believe, at the very kind suggestion of the Crown Prince.

We were, indeed, treated with the greatest kindness and consideration all through. Unlike either France or Belgium, the authorities made all the foreign units an allowance of 3 dinars (3 francs) a day for food. Moreover, there was at Nish a building where hospitality was given to members of units passing through as long as they liked to claim it. In addition, they kept us supplied with fuel, and as in the winter stoves were burning in nearly all the rooms this item was considerable. They made also very generous terms with some women doctors who came out to work under the Government, promising several hundred pounds to their relatives in the event of their death. Moreover, no other ally, as far as I am aware, has presented Red Cross decorations before the end of the war, and a large number of State Orders have even been given to members of the medical units. In one place, Mladnovatz, a fountain was erected last autumn in honour of Dr. Inglis and her Scotch missions, and one point struck us most forcibly, and that was that although some of our drastic changes in sanitation, disinfection, and above all in the nursing care of the patients, might have raised in lesser minds annoyance at the unavoidable criticism of their methods that they involved, we never saw anything but the most gracious and ungrudging readiness to comply with our demands. They were obviously intensely delighted, too, when any members of the unit recovered from serious illness—the director of one of the typhus hospitals, for

instance, on one occasion threatening a dance in honour of the event.

The peasants were equally pleasant to deal with. They are often very childlike, and there is a certain naivéte in some of their ways. For instance, to the Berry Mission was given a rather early-Victorian equipage, driven by a Serb. He was clothed and especially booted by the Mission to render him watertight, and invariably, after this ceremony was completed, the driver found some urgent necessity for departure, when a more needy and unkempt brother took his place. They have very pretty manners. Even youths, at what is in England the awkward age, were infected with them. I remember one boy of fifteen who came up to see his father in hospital, gracefully bowing over the doctor's hand and kissing it, while he thanked her for the care she had bestowed. Their language is exceedingly picturesque. One day when I was at Nish, near a cemetery, a young woman was wailing for her husband, who had been killed in the war. She would wail for a short while, and then begin intoning a lament, couched somewhat in these terms: "Other women's husbands return to them at nightfall and make them glad. Why do you not come back to me? Why is it that you are so still? I can only see you singing coming home in the evening, rejoicing in your strength. Is it true that Death holds you and will not set you free? Even then, why will you not let me come to you? Why do you refuse me entry? Unbar the door, unbar the door, I say, and I will come down." The woman would then continue her wail, and then once again utter the above refrain. I found coming home through Russia a very similar beauty of language. The English residents in Petrograd support a hospital for Russian soldiers, and the wife of the Ambassador interests herself in their wives and children, and sends them presents. I saw several letters of thanks, one of which, perhaps the most striking, ran somewhat on these lines. "Dear Lady of Bounty," it began, and it went on to describe the happiness that the reception of the gifts had caused, and to ask for a photograph of the donor as the children wished to place it beside their eikons. Then it continued: "But I am only a poor peasant woman, and I cannot express myself as I should, for truly as far as the eye sees and the ear hears, so far does your bounty extend."

The Serbian language itself closely resembles Russian. It reveals the Serb as a very contented creature, as the word one mostly hears in conversation is the word "dobra"—good. The word for bad one never hears; they simply say "not good." The fact that the Austrian orderlies spoke both German and Serbian made it rather a temptation to rub up one's ancient German rather than learn a new language. But it was remarkable what satisfactory conversations the least intelligent of us could hold. If one knew the one word "dobra," for instance, one proceeded thus: One entered the ward and addressed the patient in an inquiring and sympathetic tone, asking "dobra"? To this he would answer "dobra, doctor, dobra." One would then respond genially "dobra, dobra," and a conversation pleasing to all parties terminated, after which one addressed oneself to the Austrian orderly. But very often the reply to one's first "dobra," was given in a long rambling speech. This enabled one to shine far more, because one listened with care and then repeated it again in a sympathetic tone, which sounded as if one had understood the whole. The worst part of the language was the writing. Some of the letters were the same as those of the English alphabet, but half of these meant something different, and to make confusion more confounded they even varied in meaning where they could from the Greek letters.

The people are very democratic. The aristocracy, they say, was killed off by the Turks some six or seven centuries ago, so that they are now a race of sturdy peasant proprietors. Some of the best officers have been farmers, and a local grocer may, for instance, become aide-de-camp to a general, and on one occasion an M.P. came to our wayside dispensary at Kragujevatz.

In the few years since the Turkish yoke was thrown off, they have accomplished many things. They have started education, and we were much struck on visiting the site for the new Royal summer resort with the order in which they had proceeded with their public buildings. School and hospital had been first finished then a beautiful marble church erected, and finally the King's palace was about to be begun when the war broke out.

As regards poverty, we were most of us pleasantly surprised, for, with the exception of the refugees, such sordid poverty as one sees in our own slums we never came across. Living as they do on their own soil, they have the bare necessaries of existence, though, as there is a total absence of accumulated wealth in the country, they have absolutely nothing to draw

upon in times of disaster; and if Belgian refugees are pitiful and needy, Serbian ones are a thousand-fold more so. The women do the weaving, and since now they have been (very successfully) tilling the ground while their husbands are at the war, they have had to forego their usual occupations, and this gives the people a rather out-at-elbows appearance. But, ample though our stocks of misfits and second-hand clothes were, we seldom had the face to offer our ugly garments in place of their beautiful ones. Better, in the summer anyway, a few picturesque rags than ill-fitting British respectability. The Serbian love of colour was a continual joy; even in the typhus hospital it brightened up the dreary wards. During fever the Serbian wraps round head and body damp towels. These are striped with bright blue, red or green, and the same colour would be repeated in brilliant buttons on the night gear. The women's skirts hang in two full flounces. The design is a kind of Scotch plaid, but of such a sort never seen on sea or land, vivid pink and green in colouring, and oblong in pattern rather than square. The men wear a brilliant cummerbund, tightly wound round their waists, their figure as a consequence being very much slighter than that of the women. Reflecting on the aspersions cast on women's tight attire some years since, one wondered whether the men's digestive troubles were also a consequence. The socks are also radiant, the plainest having wreaths of brilliant roses worked round the top. But the *pièce de résistance* for both sexes is a leather jerkin, decorated in front with leather appliqué work, each petal of a huge flower being formed of a different colour, yellow, crimson, blue, etc. Leather pockets of still other shades, wools and even bits of mirror complete the design, and the whole is lined with lamb's-wool. We were surprised sometimes to see these jerkins worn up to the dispensary, with a temperature of 90 degrees in the shade; but we presumed that to appear in one's best clothes was meant as a compliment. The trying part was that it was often impossible to buy the garments or rugs, etc., that one desired, as they were just heirlooms made at home and there was no open market for them. At Vrnjatchka Banja, however, one thoughtful priest had taken his fees in things of this kind, and had sold them in the old days to Austrian, and now to English visitors. The cottages of the peasants were simple, but they had almost always a little verandah, quaint chimneys, and were kept very clean. The higher authorities also lived a simple life; the chief military authority in Vrnjatchka Banja, with his wife, having just one little room in a villa, and taking all his meals out.

The postal arrangements, too, during war time anyway were primitive. One would go down to the post office to find the supply of stamps had run out, the rarer sorts being indeed at all times only obtainable in the bigger cities. Telegrams also frequently took a day to go a short distance of under fifty miles.

The Serbians are a very musical people, and they sing beautifully; do not hesitate to do so, indeed, during the hours of darkness if they are occupied out of doors. This latter trait is imitated by the animal creation in the country; in camp one heard all night long a medley of frogs and nightingales, cuckoos and cocks, the latter having no idea of waiting for the dawn.

Although the Serbians' dislike to open windows is profound, they stand surprising degrees of cold with scanty garments in the open air.

One of the most picturesque scenes I saw in the early spring was the admission, at evening time, of patients to the Scotch hospital. They would come in about six o'clock. It was twilight, and the groups of men were standing about the courtyard. On one side, half sheltered by a bough of apple-blossom, sat a clerk at a little table with a lamp busy taking down particulars. Behind him was the bath-house, but the men undressed almost completely in the open before going in, and the darkness of their skins made the whole scene look very Eastern. Just outside the bath-house were two barbers shaving, and in the foreground, their toilet completed, stood a number of pyjamad figures waiting for shoes or a helping hand to take them across to the hospital dressing-room. One of the most surprising things about the people was the mixture of patience and pugnacity. The latter quality I need not stay to urge, but the former is less well realised. Now this was the condition of affairs which obtained in Serbia last winter. In the little tea-houses, forty or fifty of the more convalescent men would lie from day to day in the charge of one or two orderlies, some of whom were Austrians. The patients themselves were of some half-dozen different nationalities, *i.e.*, Serbs together with their enemies. Their day clothes were removed—it was reported they might dress and leave if they had them—so they could not get up, and the doctor only visited to do dressings every other day. They had no money for smokes, and the price of playing cards was prohibitive—it rose at one time in Kragujevatz

to over a sovereign. The meals were neither frequent nor exciting, and the inner parts of the "gast" houses were often dark and uninviting; there was therefore nothing to do, to look at, to read, to talk about, nor even to think of. Yet despite the Western proclivities of "idle hands," only twice in the whole of my six months did I hear of any quarrelling that needed an authoritative reprimand. I consider it marvellous. Now a word or two as to their customs. Several of these are very picturesque. Early in May a day is set apart for welcoming in the spring. Before four o'clock parties begin to leave the town, to go out on foot, by bullock carts or by carriage, to some place selected for an early morning picnic. The authorities kindly invited members of our units. They provided not only a substantial breakfast of lamb, wine, coffee, etc., but musicians and dancers and the whole company took part in the Kola, the Serbian national dance.

Easter, too, was quite a festive occasion. Both Serbians and Austrians declined to do any unnecessary work, and thought some of the English not a little mad for continuing their labours at mortuaries or drains. Exquisite flowers were sent us, and decorated eggs. Wherever we went we were offered cake, wine, etc., and the Serbs still hold to the old form of Easter greeting, "Christ is risen," with the response "He is risen indeed." Not the least interesting are some of the funeral customs. Food is brought to the funeral service, and again to memorial services which are held later at intervals of some weeks, months and years. The food is partaken of by the friends and distributed to the poor, and was even given in some recent cases to the prisoners. There were tables and chairs in the railed-off graves in the town cemeteries; but the country cemeteries with their vividly-painted, odd-shaped stone obelisks and their torn discoloured flags were the most striking. Along the roadside, too, similar painted and engraved stones were raised to soldiers who had died (not necessarily in the same spot), and sometimes a crude figure of the soldier himself had been carved on the stone and then coloured.

As regards the position of the women, although there are a few doctors and dentists it cannot on the whole be called advanced. Even on ceremonious occasions, as one Serb put it in broken English, "the women do not sit on the table." This we found to be the case. The military authorities always kindly gave us a farewell dinner at the club when any member of the unit was going home, but none of their own womenfolk were ever present.

A number of Serbian women helped in the hospitals, but it was not considered the business of any to desire a place in the limelight of the firing line. Naturally all the British units coveted that most of all, and the Serbians, with their usual gracious desire to please, I fear, involved themselves several deep in their promises of priority. They perhaps hardly took us seriously at first, for I remember, the day after the air raid, the head of the medical department—having been struck by the fact that it had improved the tone and vigour of camp rather than otherwise—said to me, "I see you do really want to go to the front." Dr. Inglis also, the head of the Scotch units, said that she had been amused at the change of front on the part of the Serbians in giving excuses for her not to go north whenever a skirmish had taken place on the Danube. At first it was "No; there are shells being fired up there. You would not like it." Latterly the excuse became, "There really is nothing doing there. You would find it dull." It was to Dr. Inglis also that one Serbian remarked, "We of the progressive party are almost more grateful to you for showing what women can do, than we are for the help you have rendered to the Serbians."

One incident that occurred in the typhus hospital is worth recording. We often argued with the director the position of women in his own country and ours, and he did not always come off victor. Now on one occasion it chanced that the night sister, going round a convalescent ward, discovered to her horror that amongst forty-odd men patients there was one woman. It had happened in this wise. We had been talking for some days of opening a woman's ward, and one doctor in the town, having heard of this, sent a patient up prematurely. Not only so, but he had labelled her as too ill to wait and see the admitting doctor, so she had been carried straight in to one of the few empty beds. But naturally we could not allow this kind of thing, so we went with some urgency to see the director the first thing in the morning. "Ah," he said, with a twinkle in his eye, "you see we make no silly distinctions of sex in Serbia," whereby he got some of his own back again. The Serbians amused us too by making "no silly distinctions of sex" in camp. The nurse in charge of a ward was, of course, called "sestro," the Serbian for sister, and after we had been working for some months a clergyman joined us as orderly, who, since he

had done a good deal of V.A.D. work at home, was soon made head of a convalescent ward. He also was immediately dubbed "sestro."

The Serbians are no more sensible than ourselves in the matter of forcing a man's nationality on his wife when he marries her. Just as the custom here immensely has increased our alien difficulties, so there also in the case of suspected spies they were unable to proceed against Austrian women without the most conclusive evidence. In the case of one woman who came up to camp, the authorities could do no more than warn us that they were practically certain that she was a spy, for the contents of some telegrams she had been handling had mysteriously leaked out. But they could do nothing against her as her husband was a Serb. I was not a little amused the other day to notice that the same difficulties were troubling another of our Allies, the French, so much so that indeed they were even contemplating making it illegal to marry enemy aliens. Forbidding marriage is a large order even for war time, and it would seem such a much simpler thing to some of us to let the woman retain her own nationality.

As regards many of the Serbian laws in such matters as disposal of refuse, registration of dogs and cattle, training of midwives, sale of poisons, etc., they were admirable; though with two of them we came unwittingly into conflict. After some months we rearranged the sanitary system of the Scotch hospital, and we then required two bullocks daily to remove refuse, etc. Two came, with long Serbian names, and one of the doctors immediately rechristened them to "Huz" and "Buz." We learnt afterwards that this had caused much trouble, as to change the name of a registered Government animal requires a complicated process at law. On another occasion, the fact of the town's being feet deep in mud having made us oblivious of the fact that there was never any untidy litter about the streets such as we often see at home, one of the sisters, thinking they would not be noticed, threw a few tea leaves from a hospital window on to the road. But, alas! next morning a note came round to the doctor in charge, saying would she kindly see that this did not occur again, for if it did they would have to convene a special meeting to consider how to deal with the offender.

The day after I arrived in Kragujevatz, I went to see the medical director of the army, and apparently even in those days we were not quite certain of what part Greece was going to play, for Dr. Soltan asked him jokingly what would happen if the Greeks turned against us and we could not go home by Salonica. "Oh," he replied jestingly, "you will go home by the Serbian Sea." Italy was not then an ally, and as Serbia hoped to conquer all the Austrian territory in the peninsula, it seemed only a sensible thing to rename the Adriatic. In the main the prophecy has come true; it is, as you know, through Montenegro and Albania and across the Adriatic that those members of the various English units who have reached home without having first been taken prisoners have come.

It is a matter for infinite regret that when Serbia had never before been so well supplied with medical and surgical personnel, appliances and stores (they had enough in the country to last two years), that all should have been rendered practically useless owing to the tragic rapidity of the invasion. In the three weeks after fighting began, and before they evacuated Kragujevatz, the Stobart unit alone attended to 1,000 patients, but all to little avail—they had to be left to be taken prisoners. Along the route the march was terrible enough for healthy men and women, short as they so often were of food, even healthy youths could not stand it; the boys approaching military age, who were coming out of Serbia, were in many cases unable to survive the rigours of the journey, and simply fell by the wayside.

As an Englishwoman, there is one fact that seems to me to sum up the tragedy, the hope deferred and the pathos of the whole thing more than any other, and it is this. For the first few months that I was out in Serbia it was our constant expectation that the English troops from the Dardanelles would be brought up to help in an offensive movement, as soon as Constantinople had fallen. True this was only to be talked of below one's breath, but sundry little vademecums, in Serb and English, full of military terms fell into our hands, and we were unable to believe that the authorities had chosen this particular moment to educate the mind of the British Tommy in the Slav languages without some useful purpose to subserve. Well, we know that Constantinople did not fall, but all the same there came a time when Serb and English both spoke openly of the help that was daily, nay hourly, expected from the advance of our men, and so great was their faith that a member of our unit, who came by a cattle truck on the last Serbian train to reach Salonica, told me that all the villages she passed through,

from Nish downwards, were decorated in honour of the advance of the Allies.

[The paper was illustrated by a number of lantern-slides.]

MRS. J. GORDON described the journey of herself and husband and party on their retreat from Serbia. Her husband was put in charge of some Englishmen of military age, and told to get them out of the country as best he could, as he knew something not only of the country but of the language, and had worked out on the map a new route. They left Vrnjatchka Banja about five o'clock, and waited for a train until nearly midnight, when the train came in quite full, and they were told by the stationmaster they must come again to-morrow. However, they managed to get on the top of the train with their clothing and blankets, and arrived at Kraliévo at two o'clock next morning, having spent most of the journey in obeying the stationmaster's instructions to "duck when you come to the railway bridges." On arrival at the town, in order to find accommodation they entered an open door where there was a light and found themselves in the telegraph office, and were told to try somewhere else. Around the corner a waiting-room was found absolutely crowded with people, and ultimately the party returned to the telegraph office, and, in spite of protest, lay down to sleep. The same difficulty in finding accommodation was experienced by some French doctors and an English girl from the Stobart unit. During the next few days they lived in a tent and gradually collected the men who were to go with the party. The guns seemed to be getting nearer every day. Dr. Churchill managed to get ten carriages which were like greengrocers' carts, and which were used to carry food obtained from a Red Cross train. The rice was so full of fleas that they had to boil and eat rice and fleas together, the other food consisting of margarine, biscuits, and bully beef. At the café, after a long wait, it was necessary to take part in a stampede in order to get coffee and meat. Bread was scarce, and only obtained with great difficulty. After a three days' halt the party started off, alternately walking and driving. They camped at night in muddy lanes, lying on mackintosh sheets in the rain. On reaching Rashka, they found everybody of importance had arrived there, and bread was ten francs a loaf, and hard to obtain at that. Austrian prisoners were given a loaf for four men for three days. The party managed to obtain leave to go on to Novibazar, although everyone declared there was no such road as Mr. Gordon had worked out on the map. At Novibazar, on inquiry of some Albanians, they were told it was quite possible to get across the mountains, and for thirteen hours they were climbing up through the mud. Everywhere the party, which numbered thirteen, had all to sleep on one floor. They were sixteen days at first without taking off their clothes and walking from dawn to dusk, living on rice and curry. In an Albanian house they found a room containing fourteen people, and an old woman offered to share her bed with the two ladies of the party, a bed which appeared to have been slept on for many years without having been once cleaned. The house was so small that two of the men had to sleep on a shelf. During the night someone unluckily struck a match and discovered that the whole place was streaming with bugs. The ventilation being bad, someone opened the street door, towards which all the savage dogs outside immediately rushed; if they had got into the room they would have made short work of the party. Miss Brindley was a cheerful travelling companion, never tired, and always ready to do anything for anybody. A boat had been arranged for to take the party to Scutari, but the captain would not sail as he said he was waiting for mattresses, and some hours later it was found that a mistake had been made on the telephone, the word "mattress" and "stranger" being almost the same in the Serbian language. At last a little French boat was obtained, and the party set sail. In the distance was an English cruiser, and a short distance away an Italian torpedo boat, while quite close could be seen the periscope of a submarine, so it was considered by the sailors that they were being well looked after, but on arrival in Brindisi they were told that the submarine was an Austrian one. The whole journey took five weeks, all walking.

On the proposition of the CHAIRMAN, a hearty vote of thanks was accorded to Miss Hanson for her paper, and the meeting then terminated.

THE CLOSING OF MUSEUMS.

Deputations from the Museums Association, the National Art Collections Fund, and the Imperial Arts League, with representatives of several other influential bodies, were received by the Prime Minister on Thursday, February 10th, and a summary of the proceedings appeared in the *Times* of February 11th. The deputations succeeded in obtaining the concessions that the zoological portion of the British Museum (Natural History) and the manuscript room at the British Museum should remain open, and elicited from Mr. Asquith confirmation of the statement that the Government had decided not to close either the Victoria and Albert Museum or the National Gallery.

But the Prime Minister stated with regard to provincial museums and art galleries that each community must decide for itself; the example of the Government need not necessarily be followed. The Museums Association suggest that in the event of a proposition being made to close any local museum it should be pointed out that the Retrenchment Committee's proposals have aroused a storm of public indignation, and that the Government has not considered it advisable to adopt by any means the whole of their recommendations. In provincial towns, too, there is

usually only one institution of the kind, and to close that one would mean an end to all the facilities a museum and art gallery affords. In London, however, there are many, and the closing of a few institutions, inadvisable as it seems, does not mean so complete a deprivation.

The opinion was authoritatively expressed after the interview, and has been emphasized since, that every effort should be made to carry the case of the British Museum to the House of Commons, and the Association suggests that each curator should at once organise an influentially signed letter to the member or members for his district, asking him to press for the exclusion of this great institution from the closing order.

IRON DEPOSITS OF BRAZIL.

Although geographically nearly as large as the United States and in many places highly mineralised, Brazil is almost unexploited as a mining proposition. The mining laws of the country have recently been remodelled in a manner that provides a decided step toward modernisation and practicable applicability; but this legislation will not overcome the lack of transportation facilities from the interior and the high cost of freights and of labour, which have hitherto been obstacles sufficient to keep the truly great mineral resources of the Republic almost untouched.

Of Brazil's iron ores, the hematites are in Minas Geraes, Matto Grosso, Goyaz, and Bahia; the magnetites (some titaniferous) in São Paulo, Parana, Santa Catharina, and Rio Grande do Sul. According to a report by the United States Consul-General at Rio de Janeiro, the most important deposits by far are those of the State of Minas Geraes. Through the central part of Minas Geraes extends the Serra de Espinhaço in a northerly-southerly direction. In this range of mountains are nearly all of the mineral deposits of the State. The great iron area seems really to be within a well-defined rectangle, fifty-six miles long by thirty-seven miles wide, with Burnier on the south side, Sabara on the north side, and Santa Barbara and Marianna on the east. In addition to the ores within this rectangle, scattered deposits extend northerly toward Diamentina, so that the high-grade iron-bearing formations probably occupy an area of some 2,200 square miles. If the lower-grade deposits are also considered, the area will be doubled in extent.

Three railways either tap or are projected to tap this district. The most important is the Government-owned line (the Central Railway), which enters the iron area near its south-western limit at Burnier, and extends northward to Sabara. It also has branches extending from Burnier to Marianna and from Sabara to Santa Barbara. From Rio de Janeiro, the nearest seaport, to Burnier is about 370 miles, and to this point the line is broad-gauge (5·25 ft.), while from Burnier to the other points the line is reduced in gauge to 3·28 ft. Another railway, the British-owned Leopoldina, does not enter this main rectangle, but is built to tap the deposits at Itabirra de Matto Dentro, north of the rectangle. Its seaport is also Rio de Janeiro, and the distance from Rio to Itabirra is about 390 miles. Still another railway, French-owned, is partially constructed to operate between the seaport Victoria and Itabirra de Matteo Dentro, a distance also of about 390 miles.

Classification of Ores—Probable Tonnage.

The ores may be classified as follows:—

(1) Bedded ores: (*a*) Very thick, bedded, massive hematite, including the dense, hard blue and the fine and coarse specular varieties and martite; beds are up to 300 ft. in width and a mile in length; (*b*) thin bedded laminated hematite, fine grained or crystalline, hard and soft; beds not so wide as (*a*), but of great length.

(2) Fragmental ores: (*a*) Canga, a conglomerate of hematite pebbles cemented together with limonite; (*b*) extensive beds of hematite "float" (rubble); (*c*) sand ore; "float" mixed with sands in river bottoms and elsewhere.

(3) Secondary ores, carbonates, etc.

The important ores commercially are the bedded hematites, both thick and thin, the Canga conglomerates, and the rubble ores.

In order to give some idea of the extent of the deposits, the Servico Geologico do Brazil selected nine of the largest and entirely exposed deposits and computed the cubic contents of each separately. These are of the bedded (highest grade) type, and are not assumed to have an extension below the surface of the surrounding country. On this basis they gave an estimated tonnage of 988,000,000. Dr. Orville Derby, the director of the Geological Service of Brazil, thinks this figure can conservatively be doubled, which tonnage about equals the total reserve of the Lake Superior ores to-day.

In addition to the above-estimated tonnage, which includes the highest grade ore only, there are known to exist millions of tons of the lower grade Canga and rubble ores. One deposit of rubble is estimated to contain 20,000,000 tons, while the Canga ores, running higher than 50 per cent. iron, would perhaps total 1,710,000,000 tons.

SUGAR-BEET GROWING IN EAST ANGLIA.

Sugar-beet growing is steadily on the increase in East Anglia, says the *Agricultural Gazette*. The sugar-beet factory at Cantley has this season received 20,000 tons of beet—a total which is 6,000 in excess of the previous year's consignments. These results are satisfactory in more ways than one, but more especially because they

tend to indicate that agriculturists, whose help is absolutely essential, are prepared to grow beet, without which it would be impossible to establish the sugar-beet industry in this country. Judging by the results just referred to, there is good ground for believing that it is only the beginning of a prosperous time for the manufacture of sugar in this country from home-grown beet. The officials of the factory, and more especially those who are constantly in touch with the farmers of the Eastern Counties, have sanguine hopes for the future. This is the fourth year of the factory, and in that time quite as good progress has been made as resulted on the ten years that were taken to establish the industry in Holland. The increase in the area of land put down to beet in Suffolk and Norfolk last year was highly encouraging; but if the acreage should increase in the next three years at the same ratio as it has done in the past three years, then the question will certainly arise of the necessity of erecting another factory, because then the capacity of the one at Cantley would not be equal to such a quantity of beet as would then be grown.

Twenty thousand tons of beet at the rate of 800 tons a day is now in the process of being converted into sugar at the Cantley factory; but this is only a third of the capacity of the factory, which, should occasion arise, will be able to deal with something like 60,000 tons in the season. Therefore, if the need should arise—and of this there are most hopeful signs—for putting up another factory, say, in Suffolk, it would probably be one capable of a larger output, with a capacity, as in the case with the biggest in Holland, up to 1,700 tons a day. There is one important factor which should contribute to the success of this new industry, and it is this—the sugar now being manufactured at Cantley is superior to anything made in Germany, from whence this country has derived such large supplies, amounting in value to as much as £13,000,000 annually in recent years.

THE FOREIGN TRADE OF ITALY IN 1914.

With the exception of beverages, spirits, and oils, all the classes into which the import trade of Italy is divided showed a marked decrease in 1914, especially as regards cereals, raw hides, raw silks, cocoons, coals, minerals, woollen goods, and raw cotton. The olive-oil crop of 1913 was a very poor one, and large consignments had to be purchased from Spain, Greece, and Tunis. The wine crop in 1913 was an abundant one against that of 1912. Exports consequently increased chiefly in connection with wine in casks sent to Switzerland, France, the United States, and Germany. Smaller consignments were forwarded to Brazil, the Argentine Republic, and Uruguay. The heavy fall in the exportation of vermouth is attributable to a decrease in the demand from the Argentine Republic and from Germany, two of Italy's good customers in respect of this article. Viewing the trade in colonial goods, there was a fall in the imports of all the items with the exception of manufactured tobacco, larger orders having been placed abroad for cigars and cigarettes. The decrease in the importation of sugar is due to the abundant home production, as the beetroot crop in 1913 was almost double that of the average yearly one. The 1914 crop has been, on the contrary, a very poor one, and that fact, together with the damage done to the sugar factories of Avezzano by an earthquake, called for a larger importation of sugar in 1915.

With regard to cotton, Italy had about 5,000,000 spindles in 1914. The previous year had been better than its predecessors as regards the exportation of cotton goods, but 1914 showed another and a most marked step backward. The importation of the raw material fell from 4,037,616 to 3,813,400 cwts. The United States and Turkey in Asia lost much ground, while the importation from British India increased, and that from Egypt remained almost unchanged.

The Italian silk industry, which is the most important in the country, suffered from the serious apprehension first of a fresh Balkan war and later on from the stringency of the monetary market. Finally the outbreak of the European war rendered the loss of silk factories heavier than could ever have been anticipated. Since the outbreak of war Italy has experienced the greatest difficulty in getting timber from Austria-Hungary, her chief supplier, and the importation of this commodity decreased very much. The Government has for some years past realised the necessity of encouraging reafforestation, with a view to rendering Italy independent of foreign countries for the supply of timber, the importation of which averages 1,250,000 tons per year. But for many years to come Italy will have to import large quantities of timber.

With regard to the details of importation of boots and shoes in the years 1912–14, in the latter year Germany sprang into the premier place previously occupied by England. Also in respect of machinery, Germany seems to have supplanted the United Kingdom's place for the supply of gas and air motors, while orders for spinning machinery continue to be shared by the two countries. A slight advance has been made by the United Kingdom in the exportation to Italy of agricultural machinery, but the United States and Germany continue to be the chief suppliers. The latter country has doubled the exportation of electric dynamos in Italy, while the United Kingdom and Austria-Hungary have lost much ground. The heavy fall in scientific instruments consigned to Italy was shared by Germany, the chief supplier, France, and, to a less extent, by the United Kingdom. The importation of coal into Italy has declined owing to the increased

rates of freight. An attempt was made to get coal from the United States, and the importation from the States was more than three times that of 1913. Nevertheless, the coal-supplying countries are headed by the United Kingdom, which occupies conspicuously the first place in the list. Nearly all the cereal crops in Italy in 1914 were smaller than in 1913, but the wheat yield was not only much below that of 1913, but was inferior to the average of the previous five years.

UTILISING SOUTHERN SCRUB PALMETTO IN THE UNITED STATES.

The scrub palmetto—of which there are several varieties, the most common being *Serenoa serrulata*—is a veritable pest in Florida, where vast areas are densely covered with the growth. Heretofore it has been put to little economic use; now, however, according to a report by a special agent of the United States Department of Commerce, a process has been perfected whereby mattings, binder twine, and the like are made from the fibre extracted from the leaves. This fibre takes dye readily, and its wearing qualities are said to surpass anything yet found in the way of floor coverings. Machines are set up in the palmetto fields and the leaves fed into them while green.

An aspect of the new industry that is of considerable value, apart from the manufacture of floor coverings, is that the twine made from the leaves is easily handled by grain binders, knots being tied without difficulty. For the manufacture of twine, however, the species known as the "cabbage" palm (*Sabal palmetto*) is employed, as it yields a fibre 3 to 5 ft. long.

The "cabbage" palm is native to the maritime parts of the United States from Florida to North Carolina. It attains a height of 40 to 50 ft., and has a crown of large palmate leaves, the blade 1 to 5 ft. in length and the footstalks long. The flowers are small, greenish, and in long racemes; the fruit black, about as long as a pea-pod, and inedible. The leaves are made into hats, mats, etc., and are also largely used for thatch. The terminal bud or "cabbage" is often eaten. The wood is extremely porous, but is preferred to every other kind of wood in North America for wharves, as it is very durable and not liable to be attacked by the teredo. The streets of Savannah and some other Southern cities are lined with these trees.

A second American species, the "saw" palmetto (*Serenoa serrulata*), occurs from South Carolina to Florida. It has a short stem and numerous clustered fan-shaped leaves, while its berries have certain medicinal properties. A still smaller species is the dwarf palmetto (*Sabal adamsonii*), a stemless plant which bears a cluster of leaves a foot or two long.

So far the scrub palmetto of Florida has been regarded as of little economic value. The leaves have been cut and shipped abroad (mainly to Germany), where they are turned into the "artificial palms" so extensively used for permanent decorative effects. Exports of palmetto leaves to Germany from the Florida customs district had an aggregate value of $11,650 (about £2,390) in the year ended June 30th, 1914. The shipments to other States of America, of course, are very much larger. The fibre has been used to some extent for mattress stuffing, and upon special order has been utilised in mixing plaster.

While the plant contains some tannic acid, the commercial production of tanning extract has so far not been attempted on a large scale because of the competition of other materials more easily and cheaply obtained. Bees evince a fondness for the flowers of the scrub palmetto, but the resulting honey is dark-coloured and has a peculiar taste.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

The Labour Supply.—For the time being the interest of producers and distributors of textile goods centres in the local tribunals, with whom it principally rests to settle the conditions under which business can be carried on. The decisions are eagerly canvassed as soon as they are made known, but the cumulative effect of the withdrawal of men from an already depleted labour supply remains to be seen from experience. The services of the pivot men are to an extent safeguarded, but no person has been engaged superfluously, and work can only become more difficult as time passes. The textile industries cannot escape the pinch exerted directly upon themselves, and upon all the surrounding industries upon whose services they rely. In the last resort all the difficulties of the hour, whether arising from fuel, dyestuff, transport or dear materials, are traceable to shortage of labour, and more shortening inevitably makes more trouble.

Trading with Germany.—In some quarters a vow to return to the use of German-made goods after the war is used as a threat to delinquent British manufacturers. The warning may be taken as the private equivalent to the adjurations coming from the public platform on the subject of education and enterprise. Both public and private discussions reveal a hearty repugnance against future dealings with the major enemy; but in public the tendency is to regard the matter simply as one of the purchase of German goods. The affair is one also of the sale of British goods, and those who have been accustomed to trade in the German market are still

at sea as to the prospect of recovering their debts and of finding their old customers solvent and disposed to trade. The attitude of the German Government is equally unknown, and in the circumstances it is not surprising to find these traders expecting little and looking rather to new markets than to the reopening of the old ones. The determination of a future trade policy is much under discussion and has taken a familiar controversial twist, but textile traders are as far off as ever from knowing how the exact situation will stand at some date hence.

Teaching the Foreigner.—Voices have been raised once more against the admission into English technical colleges of foreign students. Certainly in the day departments of some textile schools the number of foreigners has been disproportionate to that of the English-born. It may be doubted, however, whether it is in the schools that foreign students have acquired the information most directly to their purpose in imitating British goods. Manufacturers are wont to reckon mill training as the larger half of a technical education, and it is in the mill that technical science is applied to the purpose of producing saleable goods, whereas the schools are necessarily concerned more with the broad application of principles. At the instance usually of importunate customers foreign students have been admitted to mills and works, sometimes as premium-paying apprentices, and have made more or less good use of their time. It cannot be affirmed that any progress they have made has inured consistently to the disadvantage of British trade. English business is not all so insecurely held that it can be transferred promptly by the activities of observant youth, but doubtless the disposition to initiate strangers into our industrial ways has been decreased. The exchange arrangements by which young Continentals have been ushered into English works in return for a corresponding favour to an Englishman are not likely to grow more common than in the past.

The Heat-Value of Clothing.—Some experiments by Professors J. Joly and H. H. Dixon to determine the loss of heat from the body of an unclothed, as opposed to a clothed, swimmer prompt a reminder o similar experiments which might be made on and. There is no science of dress worth mention, and it may be remarkable that the facts about clothing have received as little exact study as would appear to be the case. There are points upon which precise knowledge would be welcome, even if no great results are to be apprehended. The writers upon hygiene contrive in general to exhibit a magnificent inappreciation of the differences between fabrics going by the same name, but differently constructed and manufactured from different qualities of raw material, so that many of their verdicts are crude ones. In connection with the loss of heat from the body there is room for experiments to demonstrate the comparative values of different sorts of wool. There are some empirical grounds for reckoning that clothes made of ultra-superfine wool are warmer in wear than clothing 25 per cent. heavier and made in a similar manner out of wool of the ordinary superfine quality. In turn, the latter are certainly more efficient containers of body-heat than the coarser varieties, and the scale of heat values would make at least an interesting complement to that of market values. The material employed for clothing is only one element in the larger question. As is seen in the cotton blanket, or in flannelette, a raw material not naturally favourable to the conservation of heat may be made to serve as a non-conductor by adapting the manner of its employment. The senses tell which clothing is the warmer, but there is scope for a more accurate measurement and for converting the data to practical use in textile work.

Odd Uses for Calico.—The *Journal of the Board of Agriculture* records the successful use of calico as an alternative to wood in making fowl-houses. A more useful calico than that of the ordinary drapery counter may be the heavily-sized grey sheetings and shirtings that are used for tenting in countries even as rainy as Abyssinia. Such goods are cheap in relation to their weight, and they are fairly waterproof. Lieut.-Colonel Falkner's calico poultry-houses may be likened to tents just as the shade cloths extensively used on tobacco plantations may be compared with curtains, and in any circumstances shades for plants are likely to call for more calico than tents for fowls. Light calicoes are used in some industrial premises as a ceiling to intercept the drip of condensed moisture. These odd employments for cotton fabrics have only their comparative strangeness in common with the use of cotton for shrouding refrigerated carcasses. Probably no use is unexampled, and certainly not that of cotton for shrouds, curtains and tents.

Potash from Wool.—In some other countries the carbonate of potash present in raw wool is recovered as a matter of course, the wool being steeped in plain water and the washings evaporated. In this country "de-suinting," as it is called, is done by few, and this for reasons connected with the kinds of wool principally in use. The content of potash salts varies with the soil of the pastures, and is on an average 5 per cent. in greasy Australian and Buenos Aires wools. In order to make the operation remunerative the liquor for evaporation must normally be of some such concentration as 7 per cent., and for want of encouraging returns the opportunity of recovery has been

disregarded. A process, however, has been worked out by a chemical engineer for securing the desired degree of concentration, avoiding heavy outlay in plant and dispensing with evaporators. Mr. E. V. Chambers provides for the washing of wool in the ordinary way in soap and alkali. The liquor from the machine passes into small settling tanks after flowing through a rotating disc screen for the interception of stray fibres. The liquid passes into a high-speed centrifugal separator, in which the sand and solids, the soapy water and the emulsified wool-grease are thrown into separate positions in the cage. The relatively clean soap solution is sent back to the washbowl until the requisite concentration has been reached and the potash can be recovered. The system presents economies over the older methods in any case, and the high prices of potash salts make any new source of supply exceptionally interesting at present.

Hand-made Goods.—A legal definition of the meaning attached to "homespun" may be expected shortly, and the evidence as to trade custom will presumably have final weight in determining what goods may be sold under this name without misdescription. The name conceivably implies slightly different things to different persons, denoting generally a roughly-made stuff. It need not be surprising to find the word homespun materially older than the factory era. Before there was any question of machine-spinning or power-loom, weaving yarn spun in one part of the country was sent to be woven in another, and in those times home-spun must have been read in its local rather than its purely domestic connotation. "Handspun" is more directly expressive of hand-spinning. "Handwoven" leaves the origin of the yarn open, and it is patent that some tweeds sold as hand-made or woven are, in fact, made with yarn spun by machine. The power-loom has no such advantage in output over the hand-loom as the mule has over the spinning-wheel. It can be added that the mechanism of weaving has no such impress either upon the individuality of the resultant cloth. Whether hand-made yarn is in any respect better than machine-made is a moot point; it is, in any event, very much more expensive to produce. The question of superiority is not so much one of the means as of the material employed, and the degree of twisting. The external characteristics of hand-made tweeds owe perhaps as much to the absence of finish as to all other causes. Indeed, it is not too sure that there have not been "hand-made" goods which were in fact machine-made articles sold in a rawer state than the one to which they are normally advanced. As the several names are used to justify fancy prices, or sometimes to misdescribe shoddy goods, there is reason enough for arriving at a sound understanding of what the names imply.

OBITUARY.

VISCOUNT RIDLEY.—Viscount Ridley died on the 14th inst. at Newcastle-on-Tyne. He was born in 1874, and was educated at Eton and Balliol. After leaving Oxford he became private secretary to his father, Sir Matthew White Ridley at the Home Office, and he subsequently acted as aide-de-camp to Lord Aberdeen when he was Governor-General of Canada. He became a member of the House of Commons in 1900, when he was elected for Staleybridge, and acted as private secretary to Mr. A. T. Ritchie and to Mr. Austen Chamberlain. He succeeded his father in 1904. He was an active advocate of Tariff Reform, and took a leading part in local politics. A man of many interests, he would doubtless, had his life not been prematurely cut short, have risen to an important position in the service of the State.

He became a member of the Society in 1902, and served as a Member of Council for a year in 1904–5. He took occasional part in some of the discussions, and presided at the meeting in February, 1905, when Mr. C. F. Just read a paper on "The Manufactures of the Dominion of Canada."

HON. SIR JOHN WINTHROP HACKETT, K.C.M.G., M.A., LL.D.—The death on the 19th inst. at Perth, West Australia, of the Hon. Sir John Winthrop Hackett is announced. He was born at Lordello, County Dublin, in 1848, and was educated at Trinity College, Dublin. In 1874 he was called to the Irish Bar, and after his emigration to Australia he joined the Bars of New South Wales, Western Australia, and Victoria. He was editor and proprietor of the *West Australian* and *Western Mail* newspapers. He took a very active part in political and other affairs in Australia, and occupied many important public positions in his own colony—amongst them he was the first Chancellor of Perth University. He was knighted in 1911, and became a K.C.M.G. in 1913.

He joined the Society in 1906, and in the following year he read a paper here on "Social and Economic Conditions in Australia," for which he was awarded the Society's silver medal.

GENERAL NOTES.

PASTELS BY JOHN RUSSELL, R.A.—A small collection of pastels by John Russell, R.A. (born 1745, died 1806), the most famous English painter in that medium, has been arranged in Room 81 at the Victoria and Albert Museum. It includes two family portraits lent by Mr. C. B. Pattrick, four works lent by a descendant of the artist, and eight examples belonging to the Museum. In his youth Russell obtained three premiums from the Society of Arts: in 1758, five guineas for a pen-and-ink sketch of "An Hussar, after Worledge," in the class of young persons under fourteen who "had

never been taught"; in 1759 four guineas, for a drawing "A Belisarius, after Strange," in the class under fourteen; and in 1760 three guineas in the class under sixteen, for a drawing the subject of which is not recorded.

Sulphate of Ammonia.—Lord Selborne, in a leaflet issued by the Board of Agriculture and Fisheries, calls the attention of farmers to the fact that the decision to suspend the issue of licences for the export of sulphate of ammonia was based on the assumption that the home demand for this fertiliser would be substantially increased. Unless therefore farmers at once increase their demand, the result will be that stocks will accumulate and the output will be curtailed. In view of the importance of using every effort to stimulate the production of maximum crops during the war, in the interests both of agriculture and of the nation generally, Lord Selborne appeals to farmers to avail themselves without delay of the present opportunity to procure supplies of sulphate of ammonia for spring use.

Potash from Feldspar and Distillery Waste.—Several new methods of increasing the supply of potash have recently been brought to the attention of the United States Bureau of Foreign and Domestic Commerce. One of the most promising of these efforts to find a substitute for German fertilisers is a patent lately taken out by a Canadian for a method of using the potash in ordinary feldspar. The process is a simple one, consisting of heating the feldspar with limestone and iron oxide at a temperature of about 2,200° F., which produces a partly-fused mass that is easily decomposed by a weak acid. From this product the potash salts can readily be extracted for further purification. The inventor has been in consultation with Dr. Norton, the expert who has been studying the potash and dyestuffs situations for the Bureau of Foreign and Domestic Commerce, and it seems very possible that a greatly simplified method of transforming feldspar into fertiliser will soon be available. A practical "try-out" for another method of obtaining potash fertiliser will take place at a New Orleans distillery where molasses are used in large quantities. It is a fact, says the Bureau, that 106 tons of potash are wasted daily by the twenty-five or more distilleries in the United States that subject molasses to processes of fermentation. The New Orleans company is planning to instal the process of saving the potash in distillery waste recently brought to the attention of the public by the Bureau of Commerce. It should be possible, adds the Bureau, to make fertiliser from this otherwise worthless material at a price that will meet competition even after the war is over.

Concrete as a Protection from Rust.—In connection with the enlargement of the Victoria terminus of the London, Brighton, and South Coast Railway, a covering of fine concrete to all the overbridges in the station has been adopted. The ironwork is thus protected from corrosion from the weather, and from the steam emitted by the locomotives passing under it. At the Cortland Street ferry end of the Pennsylvania and New York City Railway, according to Mr. Henry Adams, President of the Concrete Institute, the whole of the steelwork has been covered with a thin coating of sand and cement, sprayed on it by means of a "cement gun" after carefully cleaning the surfaces of the steelwork. A test piece successfully resisted the most severe trials. It was kept in moist salt air for three days, in salt water for three days, in a temperature of 5° below zero for forty-eight hours, and then allowed to thaw in a warm room; then it was placed on a boiler subjected to a heat of 110° for three days; then it was dropped 2 ft. on a wooden floor, again on a concrete one, and showed no signs of cracking.

Microstructural Changes in Annealed Bronze.—The properties of cast steel may be greatly improved as a result of refining the grain by proper annealing. The changes occurring in cast brasses and bronzes upon annealing are by many metalworkers regarded in the same light. A study has just been completed by the United States Bureau of Standards of the annealing of bronze, using the commercially important alloy zinc bronze (copper 88, tin 10, zinc 2) as a type. The results show that bronze is very different in its behaviour from steel, and shows no recrystallisation or grain refining, unless it has been previously cold worked as by rolling or hammering. Copies of this publication may be obtained upon application to the Bureau of Standards, Washington, D.C.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

March 1.—Charles Delchevalerie, "Maeterlinck, Verhaeren et les Lettres belges." George Granville Leveson-Gower will preside.

March 8.—Charles R. Darling, A.R.C.Sc.I., F.I.C., "Optical Appliances in Warfare." Dr. R. T. Glazebrook, C.B., F.R.S., Director of the National Physical Laboratory, will preside.

March 15.—Edward Percy Stebbing, F.L.S., F.R.G.S., Head of the Department of Forestry, University of Edinburgh, "Forestry and the War."

March 22.—Rev. P. H. Ditchfield, "The England of Shakespeare."

March 29.—R. W. Seton-Watson, D.Litt., "Pan-German Aspirations in the Near East."

April 5.—Arthur S. Jennings, "Painting by Dipping, Spraying, and other Mechanical Means."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m. :—

APRIL 6.—PROFESSOR WYNDHAM R. DUNSTAN, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India." THE RIGHT HON. LORD ISLINGTON, G.C.M.G., will preside.

APRIL 27.—JAMES MACKENNA, M.A., I.C.S. (Deputy Commissioner, Myaungmya, Burma, and designated Agricultural Adviser to the Government of India), "Scientific Agriculture in India."

MAY 18.—SARDAR DALJIT SINGH, C.S.I., "The Sikhs."

COLONIAL SECTION.

Tuesday afternoon, at 4.30 p.m. :—

APRIL 11.—SIR DANIEL MORRIS, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland."

Dates to be hereafter announced :—

W. A. CRAIGIE, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

VICTOR HORTA, Directeur de l'Académie Royale des Beaux-Arts de la Ville de Bruxelles, "Belgian Architecture."

PROFESSOR T. G. MASARYK, "The Slavonic Peoples."

G. P. BAKER, "Hindu Hand-painted Calicoes of the Seventeenth and Eighteenth Centuries, and their Influence on the Tinctorial Arts of Europe."

PERCY HURD, "Next Steps in Empire Partnership."

FOTHERGILL LECTURES.

Monday afternoons, at 4.30 p.m. :—

EDWARD A. REEVES, F.R.A.S., Map Curator, Royal Geographical Society, "Surveying." Three Lectures.

March 27, April 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 28...Economics and Political Science, London School of, Clare-market, W.C., 5 p.m. Hon. W. P. Reeves, "The Balkan States." (Lecture IV.)

Medicine, Royal Society of, 1, Wimpole-street, W., 5.30 p.m. Discussion on "War Injuries to the Jaws and Face."

Actuaries, Institute of, Staple Inn Hall, Holborn, W.C., 5 p.m.

TUESDAY, FEBRUARY 29...Royal Institution, Albemarle-street, W., 3 p.m. Dr. E. J. Russell, "The Plant and the Soil—Nature's Cycle." (Lecture I.)

WEDNESDAY, MARCH 1...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mons. C. Delchevalerie, "Maeterlinck, Verhaeren et les Lettres belges."

Civil Engineers of Ireland, Institution of, 35, Dawson-street, Dublin, 8 p.m.

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m. 1. Messrs. E. J. Bevan and W. Bacon, "The Manufacture of English Chemical Filter Paper." 2. Mr. A. W. Knapp, "Pink Colour on the Surface of Margarine." 3. Mr. S. B. Phillips, "A Rapid Method for the Estimation of Fat in Powders." 4. Mr. C. E. Stacy, "A New Colour Reaction for Aloes."

Sanitary Engineers, Institute of, Caxton Hall, Westminster, S.W., 7 p.m. Lieutenant B. R. Hebblethwaite, "Sanitary Work at the Front with the Expeditionary Force."

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Rev. A. du Bulay Hill, "A Saxon Church at East Bridgford, with Some Notes on Pre-Norman Remains in Nottinghamshire."

University of London, King's College, Strand, W.C., 5.15 p.m. Professor S. Askenazy, "The Spirit of Poland."

THURSDAY, MARCH 2...Royal Society, Burlington House, W., 4.30 p.m.

Linnean Society, Burlington House, W., 8 p.m. 1. Dr. Annie Porter, "Exhibit of *Giardia* (*Lamblia*) *intestinalis* from Cases of Diarrhœa in Soldiers, the Infections being Contracted in Flanders." 2. Dr. J. D. F. Gilchrist, "Larval and Post-Larval Stages of *Jasus lalandii*." 3. Mr. B. M. Griffiths, "The August Heleoplankton of some North Worcestershire Pools." 4. Dr. O. Stapf, "The Distribution of the Box-tree, *Buxus sempervirens*."

Child Study Society, at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W., 6 p.m. Mr. A. E. Hayes, "The Danish Child at School."

Chemical Society, Burlington House, W., 8.30 p.m. 1. Messrs. H. R. Procter and J. A. Wilson, "The Acid-gelatine Equilibrium." 2. Mr. W. Caldwell, "Chloro- and Bromotriethylphosphinoacetaldehyde."

Royal Institution, Albemarle-street, W., 5.30 p.m. Professor L. W. King, "Recent Excavations in Mesopotamia. Lecture I.—The Northern Capitals, Nineveh and Asshur."

Medicine, Royal Society of, 1, Wimpole-street, W., 5.30 p.m. Dr. Clippingdale, "The Thames Valley—Certain of its Natural and Medical Attributes."

FRIDAY, MARCH 3...Royal Institution, Albemarle-street, W., 5.30 p.m. Professor S. P. Thompson, "Corona and other Forms of Electric Discharge."

Geologists' Association, University College, W.C., 7.30 p.m.

University of London, Bedford College, York Gate, Regent's Park, N.W., 5 p.m. Canon Hastings Rashdall, "The International Crisis: the Theory of the State."

Medicine, Royal Society of, 1, Wimpole-street, W., 8.30 p.m. 1. Captain G. Marshall, "The Choice of Anæsthetics at a Casualty Clearing Station." 2. Dr. Harold Low, "An Apparatus for the Intratracheal Insufflation of Ether." 3. Dr. F. E. Shipway, "An Apparatus for the Administration of Warm Anæsthetic Vapours."

SATURDAY, MARCH 4...Royal Institution, Albemarle-street, W., 3 p.m. Hon. J. W. Fortescue, "Eminent Generals of the last Great War. Lecture III.—Wellington's Divisional Commanders."

Journal of the Royal Society of Arts.

No. 3,302. VOL. LXIV.

FRIDAY, MARCH 3, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

NEXT WEEK.

WEDNESDAY, MARCH 8th, 4.30 p.m. (Ordinary Meeting.) CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Optical Appliances in Warfare." RICHARD T. GLAZEBROOK, C.B., M.A., D.Sc., F.R.S., Director of the National Physical Laboratory, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, February 17th, 1916; LIEUT.-COLONEL SIR DAVID BARR, K.C.S.I., in the chair.

The paper read was—

THE SAINTS OF PANDHARPUR: THE DAWN OF THE MARATHA POWER.

By C. A. KINCAID, C.V.O., I.C.S.,
Author of "Deccan Nursery Tales," "The Indian Heroes," "The Tale of a Tulsi Plant," etc.

The subject of my paper is the early dawn of the Maratha power. I wish, however, to preface it by some explanatory remarks. In the course of it I have carefully abstained from laying down that any particular fact is legendary and not historical. The men whose names I shall mention are worshipped either as divine saints or as incarnations of various deities. To hazard publicly an opinion that any of their recorded miracles never occurred might possibly give great offence.

That you may better understand the subject of this paper, I would ask you for a moment to come back with me to the year A.D. 1192. At that time Delhi was the capital of Prithvi Raj, chief of the Chohan Rajputs; Kanauj was the capital of the Rathors. South of the Vindhya Mountains a new dynasty had just emerged. One Bhillama Yadhav, a Maratha chief of the same family as the rulers of Dhorasamudra in Mysore, had, after a series of battles, declared himself independent and had founded as his capital the town of Devgiri, now known as Daulatabad. In the Punjab a foreigner had established himself. Between the Afghan cities of Ghazni and Herat run the hills of Ghor. The wild tribes of that region had overpowered the successors of Mahmud the Ghaznivide, who more than sixty years before had raided India to sack Somnath; and, led by a great captain, Muizzadin, better known as Mahomed Ghori, they had consolidated into a powerful kingdom, Sind, the North-Western Punjab and Eastern Afghanistan. Mahomed Ghori had, in 1191, tried to push further eastwards into India; but he had been severely defeated by Prithvi Raj. The year A.D. 1192 was to see the Afghan's revenge. On the scene of his previous defeat he overthrew the Chohans, and on the banks of the Jumna he defeated the Rathors.

By these two victories Mahomed Ghori founded the Mussulman kingdom of Delhi, which was to last over 600 years, and in the course of his reign most of Northern India fell a prey to his arms. The country south of the Vindhyas was not immediately affected by the success of the Ghori Afghans. For 100 years afterwards the Yadhav dynasty not only endured but prospered. Thus when, in 1290, Jalaluddin Firoz Khilji became Emperor of Delhi, Ramdev Yadhav, the fifth in descent from Bhillama, had been ruling over Devgiri for nineteen years. For four years more he continued to rule without any mishap, when a palace squabble in Delhi struck down his prosperity. Jalaluddin's nephew Alauddin was married to the Emperor's daughter. The marriage was unhappy, and Alauddin feared that his wife would induce her father to kill or imprison her husband. He asked for and obtained leave to collect an army to attack

Chanderi. Then he passed beyond it into the Deccan, and without any warning raided Devgiri. The raid was a complete success. The Maratha chief offered hardly any resistance and gladly paid a huge ransom. With it and the prestige of victory Alauddin returned to Delhi, and not long afterwards murdered his uncle and became emperor in his stead. Once master of the Delhi throne, Alauddin reduced Devgiri to vassalage. His successor, Kutubuddin Mubarak, completely subdued it.

The extraordinary collapse of Devgiri was probably due to other causes than the superior physique or courage of the Mussulmans. The previous establishment of the Spaniards in the Caribbean Sea was of itself the main cause of the downfall of the Aztecs. The ferment in the mind of Montezuma more surely caused his ruin than the military skill of Cortez. In the same way the conquest of the great Rajput kingdoms of the North, and the intrusion of another religion—that of Islam—into India, upset all the previous conceptions of the Hindus. The Brahmans pronounced that the domination of the Mussulmans was foreordained to last for 30,000 years. And long before the Afghans came the Marathas had accepted them as their future conquerors. Nor did the conquest cease with the overthrow of the Yadhavs. For a moment it seemed likely that the whole Deccan would turn Mussulman. From this national calamity the Maratha race was saved by the Saints of Pandharpur.

The first of these saints was Dnyandev. Although it is impossible to fix exactly the dates of any of them, we may say with some certainty that Dnyandev was a contemporary of Alauddin and of Ramdev. The story of his birth, as told by Mahipati, is as follows. The sins of the world had so increased that Brahmadev and Shiva sought out Vishnu to consider the question. As a result of the interview Shiva took the form of Nivratti, Vishnu that of Dnyandev, and Brahmadev that of Sopana. Lastly Laxmi assumed human shape in their sister Muktabai. The method of the incarnation was as follows. The earthly father of the three brothers and their sister was one Vithoba, a Brahman from Apegaon. His wife was one Rakhmai, the daughter of a Brahman at Alandi, a small town on the Indryani, about twelve miles north of Poona. Vithoba and Rakhmai settled at Alandi, but the married pair, although happy, were childless. In a fit of melancholy, caused by the death of his parents, Vithoba went to Benares and became a *sanyasi*, or anchorite. This was a sin on his part, for no one who has a living wife and no children should take *sanyas*. Eventually his preceptor came to hear the true facts, which Vithoba had concealed, and made him return to Alandi and once again to live with his wife. This reunion led to the birth of Nivratti, Dnyandev, Sopana and Muktabai. The return, however, of Vithoba to the life of a householder, after he had taken a vow of asceticism, offended deeply the Brahmans of Alandi. They out-casted him. And when he wished to have his son Nivratti invested with the sacred thread they refused, unless he could get the Brahmans of Paithan, a holy place on the Godaveri, to give him a letter of purification. Nivratti with his two brothers and his sister went to Paithan, asked for the letter, and at first received a flat refusal. Then the Brahmans said that if Nivratti bowed to every cow, ass, hare or dog that he met, thinking the while of Brahmadev, they would relent in his favour. Lastly, hearing Dnyandev's name, they mocked him by transferring it to a buffalo that happened to pass. Dnyandev, however, was in no way disconcerted. He placed his hand on the buffalo's head. And to show that in the sight of God no earthly distinctions mattered, he made the buffalo recite the four Vedas without an error. This miracle was soon followed by another one. He called up the ancestors of his landlord to attend the *shradh* ceremony of the latter's father in place of the Brahmans who had refused his invitation owing to the presence of his four polluted lodgers. Convinced by these two miracles, the Paithan Brahmans gave the letter of purification to Nivratti, and he was duly invested with the sacred thread. To tell the miracles of Dnyandev and his brethren would take me many hours. I shall simply relate one more, which occurred at Alandi. A certain Changdev—really an incarnation of Indra—was a Brahman of extraordinary occult power and knowledge. The allotted term of his life was only 100 years. By an original device he managed to prolong it to 1,400 years. When his 100 years were on the point of closing he disengaged his soul from his body and hid it, leaving his corpse on the ground. When Yama, the god of death, came to take away Changdev's soul, he found only an empty corpse, and after a vain search for the soul had to leave on other business. Directly Yama left, Changdev's soul came out of its hiding, re-entered his body, and started on a fresh 100 years. When he had done this fourteen times he had acquired a vast amount of experience and wisdom, and

wished to try a fall with Dnyandev. Changdev did not declare open warfare. He affected to wish that Dnyandev should become his *guru*, or spiritual teacher. He wished to send him a letter to this effect, but as he could not bring himself to address Dnyandev as *tirtharup* (*i.e.*, father), he sent Dnyandev merely a blank sheet of paper. Nevertheless, Dnyandev grasped Changdev's meaning, and in reply sent him a letter of sixty-five verses. But the sense was too deep for Changdev. Unwilling to confess himself beaten, he mounted a tiger, took a snake in his hand for a whip and, followed by over one thousand pupils, he sailed through the sky until he met Dnyandev outside Alandi. Dnyandev, however, was in no way disturbed by the apparition. He mounted a wall and made it run alongside Changdev's tiger. Both man and beast were dumbfounded, and Changdev became a devout follower of Dnyandev. I may add that Changdev obtained no further extension of life. When his current one hundred years expired, Yama came again and this time carried off Changdev's soul in triumph.

The poet Namdev, to whom I shall again refer, has told in touching stanzas the death of Dnyandev. When he felt the approach of death, he asked that he might be buried at Pandharpur. But the god Krishna bade him choose Alandi as his burial place. There, amid a great company of gods and saints, Dnyandev entered alive a cave dug beneath an image of Nandi (Shiva's bull), and ordered it to be closed. A golden peepul tree grew out of his tomb. His bamboo staff took root and grew into a tree. And to-day Alandi is regarded by Marathas as only second in holiness to Pandharpur.

But let us return to our main theme. Why should Dnyandev be called a Saint of Pandharpur? Pandharpur is a very old shrine in the Sholapur district, on the banks of the Bhima. It appears to have once been a shrine of Shiva; but within historical times the worship of Shiva has been overshadowed by that of Vithal. According to Sir R. Bhandarkar, Vithal, or Vithu, is merely a Canarese corruption of Vishnu; and at Pandharpur Vithal is regarded as a synonym of Vishnu's incarnation Krishna. Now Dnyandev was a follower of Krishna; his books, the Dnyaneshwari and the Amritanubhav, glorify Krishna. By his talents and fame he made it the chief religious centre in the Deccan. Next, how did he save the Maratha race? To those who were drawn towards Islam he offered another and more warmly coloured faith. Instead of the austere prophet of Arabia, he bade men look to the wondrous child of Mathura; by holding out hopes of brighter things in a future life he enabled men better to bear their present troubles. At one time an out-caste himself, his renown as a saint proved to men of all castes that Krishna looked more to faith in him than to pure birth or sacrifice or ceremonial. Devotees of all, especially the lower, castes began to crowd to Pandharpur. One famous worshipper, Savata, was a *mali*, a gardener; Ranka was a *kumbhar*, or potter; Chokhamela was a *mhar*, one of the untouchable classes. Yet, according to Mahipati, he found such favour in the eyes of Vithal that one night, after the priests had mocked Chokhamela, Vithal's image descended from its shrine and, lifting Chokhamela from his bed, carried him inside the temple and placed him by its side. Nor did Pandharpur attract only Hindus. Kabir, a Mussulman weaver, was permitted to become one of Vithal's most ardent worshippers. Nor did her sex exclude Mirabai. Betrothed as a young girl in the usual Hindu way to a boy of her own caste and position, she fell in love with Krishna's image. And, resisting all and various persecutions, she became an ardent follower of the god, and eventually migrating to Dwarka composed there the first poems ever written in Guzarathi. But when caste ties are weakened, as Dnyandev's teaching weakened them, something else must take its place. Man, a gregarious animal, wishes to associate with other men on some common basis. The usual substitutes for caste are common religion and common language. And so it followed that all those who worshipped at Pandharpur, and could speak to each other in the language of Dnyandev, and could read his poetry, became drawn to each other. In this way the Maratha race became the Maratha nation.

I would now ask you once again to turn to political history. In 1347, about fifty years after Alauddin's first assault on Devgiri, Hasan Ganga revolted against the Delhi emperor, Mahomed Tughlak, and founded what is known as the Bahmani empire; and now for the first time since the conquest we hear of the Marathas. By the aid of the Maratha nobles the revolution succeeded. They were no longer the rough country bumpkins so easily routed by Alauddin. The poetry and metaphysics of Pandharpur had enlarged their minds; they had become capable of learning military science and of proving useful allies to a great soldier. This change in the Maratha nobles is reflected in the work of the Pandharpur poet Namdev. This famous

man deserves really a paper to himself; as it is, I can give him very little space. According to Mahipati, Namdev was an incarnation of Uddhav, the friend of Krishna. His parents, Damshet and Gonabai, were members of the Shimpi, or tailor caste, and lived at Pandharpur. They were childless, but in their old age Vithal took pity on them and granted them a son. He was not born in the usual way, but was found by Gonabai inside a shell that came floating down the Bhima River. Damshet and Gonabai accepted him gladly, and by means of another miracle Gonabai, although advanced in years and not his mother, was able to nurse him herself. Namdev always writes of himself as a contemporary of Dnyandev; but, as Sir R. Bhandarkar has pointed out, the difference between the Marathi of the two poets makes this impossible. According to Sir R. Bhandarkar, Namdev lived at the close of the fourteenth century. Taking this surmise as correct, Namdev lived some years after the Bahmani empire had been founded by the aid of the Maratha nobles. He neglected entirely his tailor's business to become an ardent psalmist of the god Vithal; but whereas Dnyandev bade his readers cast out from their minds all earthly affairs, a different tendency is to be found in Namdev's verses. He advises his followers not to make vows, fasts, or pilgrimages, or to practise austerities. They will find salvation in the remembrance of Hari (*i.e.*, Vithal). If they are so unfortunate as to have worldly duties, let them perform them; but they should, during the performance, remember god always. And here follows a delightful illustration. They should act exactly like an unfaithful wife. To the outside world she appears to be attending to her husband's comforts, but inwardly she never ceases to think of her absent lover.

At the close of the fifteenth century the Bahmani empire began to break up, and in its place arose the states of Bijapur, Ahmadnagar, Golconda, Berar and Bidar. These five states were always quarrelling; they were cut off from the Mussulman recruiting ground beyond the Himalayas. Thus the Marathas yearly obtained fresh opportunities of advancement, and by the sixteenth century we find Mores and Nimbalkars, Ghatges and Manes, Ghorpades and Daphles, holding high offices both in Ahmadnagar and Bijapur. Indeed, it is probable that within another 200 years the Mussulman Padshahs would automatically have disappeared in favour of Hindu kings had not certain events happened beyond the Vindhyas. In 1526 Babar, King of Ferghana, successfully invaded India, and founded what is known as the Moghul Empire. In 1556 his grandson Akbar became Emperor of Delhi; and he, his grandson Shah Jehan, and his great grandson Aurangzib, never ceased to covet the southern kingdoms as former provinces of the Delhi empire. The most accessible, and therefore the first victim, was Ahmadnagar, and by 1637 it had been completely annexed. It was clear that Bijapur would soon meet the same fate, and the Marathas, so far from realising their hopes of independence, seemed likely to become merely "a conscript appendage to a foreign power." Let us now see how this calamity affected the Saints of Pandharpur. In 1607 there was born at Dehu, a town fourteen miles to the north-east of Poona, one Tukaram More. He inherited a village shop, but he had no head for business. His thoughts, influenced by the sufferings of his country, turned to religion; he became bankrupt, and, leaving his wife to provide for their family as best she could, he turned for consolation to Vithoba. But the old Brahmanical opposition to saintship in inferior castes, crushed at Pandharpur, lingered at Dehu. Tukaram was forced to throw his poems into the Indryani, which passes by Dehu. Vithoba, however, befriended him, and the poems a few days later returned perfectly dry to the surface of the water. After this miracle Tukaram was hailed as a saint, and when he died at the age of forty-two or thereabouts, at Dehu, Vishnu sent his heavenly chariot to convey him to heaven. In Tukaram's works we find a distinct retreat from Namdev's position to that of the earliest saints. Nowhere have I seen any suggestion that man's duty lies in work. On the contrary, Tukaram repeats over and over again, "False is the world; Hari (*i.e.*, Vithoba) alone is real." At the same time he emphasizes the view that in the eyes of Vithoba caste has no meaning: "God does not feel ashamed to help anyone; he seeks to comfort people of all conditions."

But if the political situation made Tukaram despair, there were two men alive at this time who saw that out of it might arise freedom. The first was a Deshasth Brahman called Narayan; he was the son of a certain Suryajipant and his wife Rambai. From his earliest days the young Brahman devoted himself to the worship, not of Vithoba, but of Ramchandra the conqueror of Lanka, the seventh instead of the eighth incarnation of Vishnu. Nevertheless, Pandharpur can claim him as one of her saints,

for, according to his biographer, Narayan received a call to Pandharpur from Vithal himself. When he went there the god informed him that Rama and Vithal were one, and commanded him to visit Pandharpur at least once a year. This command Narayan did not fail to obey. The second was a lad of amazing talents, who was growing to manhood in Poona city. His father had been one of the foremost soldiers in the service of Ahmadnagar. He had tried in vain to save that kingdom, and after its fall had taken service with the king of Bijapur. The lad's mother was a descendant of the old Yadhav kings of Devgiri. His parents had quarrelled and the boy grew up under the care of his mother Jijabai and an old Brahman called Dadaji Kondev. No surroundings could have been more favourable to the growth of a daring man. The Brahman repeated to the boy the old Sanskrit tales of the Indian heroes, until the latter vowed that he would be as brave as Ramchandra and as knightly as Arjuna. At the same time Jijabai told her son legends of the glory of the old Hindu kings his ancestors, and urged him to restore at least some measure of their greatness. The boy grew into a man. He first seized the forts round Poona, and then successfully defied in turn the governments of Bijapur and Delhi. His name was Shivaji Bhosle, and he is immortal as the liberator of the Maratha nation. This, however, is not the place to write of Shivaji the conqueror. I wish to show his connection with the Saints of Pandharpur. From the first Shivaji was a deeply religious man. After his successful raid on Chandrarav More, Shivaji fortified Pratapgad. It was an anxious time, as Bijapur would certainly try to avenge their officer's death. Shivaji's thoughts turned to things spiritual. He sought a preceptor to instruct him more fully in religion. By this time the young Narayan had become a renowned saint. So fervently did he worship Ramchandra that men said that he was an incarnation of Maruti, the monkey god who helped the divine hero on his southern march. And Narayan himself took the name of *Ramdas*, or slave of Rama. Shivaji heard of him, and wished to make him his *guru* or spiritual teacher, and went to see him at Chaphal where he had built a temple to his favourite god. But Ramdas hid himself and Shivaji sought him everywhere in vain. At last Shivaji vowed that he would not touch food until he had seen the saint. Then Ramdas relented. He sent him a metrical letter exhorting him to restore the Hindu religion and to clear the country of its Mussulman oppressors. The next day Shivaji and Ramdas met. The king, delighted with the letter, was still more pleased with the saint. He would not, however, make Ramdas his *guru* without a test. He ordered him, so runs a story, to fetch a *ser* of tigress' milk. Such a task was nothing to Ramdas. He went at once into the forest, sought out a tigress with cubs, milked her, and brought back the milk to the king. From this time on Ramdas was the constant companion and spiritual guide of the king. His influence was wise and kindly. While he taught Shivaji the duties of kingship, and the divine task which lay before him of freeing his countrymen, he at the same time bade him not to be over stern, to speak no harsh words, not to cherish his anger, and not to act unjustly in any matter. And Shivaji's career shows this teaching. He gave no mercy to Afzul Khan the Bijapur general, but he treated his beaten army with the utmost consideration. Shivaji would have killed Aurangzib without scruple; but when Abaji Sondev captured, and sent as a present to the king, the beautiful daughter-in-law of Mulana Ahmad—the Mussulman governor of Kalyan—Shivaji sent her home again to her relations with all respect. In spite of his influence over Shivaji, Ramdas was wise enough not to seek to guide his campaigns. Unlike Peter the Hermit, Ramdas did not wish both to inspire and to lead a crusade. When Shivaji heard of the approach of Afzul Khan, he asked Ramdas' advice. The saint replied that he could not advise. Shivaji should pray for guidance to Bhavani, the goddess of Pratapgad. The saint knew that the king's fertile brain would, if left to itself, devise the proper measures. But when the king grew vain of his victories Ramdas did not hesitate to rebuke him. Once the king and the saint were watching the building of Samangad fort. Thousands of men were at work, all paid by the royal treasury. The king let fall some remark that showed his pride that he was the source of their livelihood. "That," replied Ramdas, "is but a small part of your great work." He then bade some workmen split open a boulder close by. In the centre was a cavity half filled with water, in the water was a frog. "O, king," said Ramdas, "who but you could have made a hole in the centre of the stone, placed a frog in it and provided it with water." The king was confused, asked the saint's forgiveness, and admitted that it was alike God who had kept alive the frog and God who cared for the needs of the workers at Samangad.

Now let us sum up the work of the Saints of Pandharpur. In the first place, they drew the thoughts of the Marathas away from Islam. Secondly, they created a centre at once literary and religious, and thus made of the race a nation. Thirdly, by their doctrines and writings they improved and enlarged the minds of the Maratha leaders, so that they became the indispensable servants of their conquerors. Fourthly, by belittling caste, they united the Maratha nation, and thus made the way smooth for the coming of a national hero. And lastly, when that hero came, great beyond human expectation—I had almost said human imagination—they made him better than great. They made him modest and just, pure minded and humane.

DISCUSSION.

THE CHAIRMAN (Lieut.-Colonel Sir David Barr, K.C.S.I.), in opening the discussion, said he thought that few of the audience when they came to the meeting had ever heard of the Saints of Pandharpur, but the author had said sufficient to prove that holy men did exist at the time and in the manner that had been related, and that they had great influence over the Maratha race. It was not until he carefully read a book on the rise of the Maratha power—written by the late Hon. Mr. Justice Ranade, a Judge of the High Court of Bombay—that he had any knowledge of the subject; and although the author had, very rightly, deprecated a discussion with regard to the religion of the Hindus, he could not refrain from reading a few sentences showing what were Mr. Justice Ranade's views on the subject. In a chapter devoted to the history of the saints and prophets of Maharashtra, he referred to their teaching as resulting in a religious and political upheaval, and continued: "The supremacy of one God, One without a Second, was the first article of the creed with every one of these saints, which they would not allow anybody to question or challenge . . . All their love has been freely poured upon the intense realisation of the everyday presence of the supreme God in the heart, in a way more convincing than eyes, or ears, or the sense of touch can realise. This constitutes the glory of the saints." Mr. Kincaid had stated that the results of the work of the Saints of Pandharpur were not only to turn the Maratha people from conversion to Islam, but to give them a greater respect for themselves, to learn that caste was not the most important thing, and that the love of God was really the sole motive which should prompt men in this life. He thought it might be said that the pure religion of the Hindus led the people to believe in the love of God, in Tennyson's words—

"That God, which ever lives and loves,
One God, one law, one element,
And one far-off divine event,
To which the whole creation moves."

He thought most people would recognise in that simple teaching the precepts of the religion in which all believed. With regard to the miracles that were performed, and the extraordinary events that happened during the lives of the saints, it must be borne in mind that our teaching from childhood was based upon myth, legend, and history as taught in the nursery, and from that was evolved the faith that grew up in us as we became older. The Hindus were perhaps more liable to these influences than we were. They were the most childlike people in the world; they were very credulous and believed almost anything they were told. They had that "faith like a little child" which the Bible says is the only means of knowing God. English children were brought up to believe in all sorts of stories; but where should we be but for nursery tales? And who would grudge the pleasure children took in peeps into fairyland? They firmly believed in the visit of Santa Claus at Christmas time, and parents devoted themselves at that period to practising a pious fraud upon their children, by seeing that Santa Claus arrived in due time, and that things were exactly as the children thought they would be. In 1887-1888, when he was Political Agent at Rewa, he became a great friend of the head priest, the Swami of Lachman Bagh, who was a very pious and good man, with whom he spent many hours sitting outside his temple, learning a great deal about the Hindu religion and the manner in which it was propagated, and being taught a few of the mantras from the Veda. Some years afterwards, when he was at Indore as Agent to the Governor-General, a great fair, which was held once in a period of so many years, and was attended by Hindus of various castes from all parts of India, was about to take place at Ujjain, a sacred city about forty miles from Indore. It so happened that at the time cholera, in a very virulent form, broke out at Ujjain, and he was asked to do everything in his power to stop the large gathering of 200,000, 300,000, or 400,000 pilgrims taking place, and so prevent the epidemic spreading. The pilgrims had already arrived in their thousands at Indore, and the Maharaja suggested that he (the Chairman) should enlist the assistance of some of the holy men. Accordingly he invited twenty or thirty of them to the Residency, and told them that the pilgrimage to Ujjain was likely to result in a serious outbreak of cholera, and he begged them not to go there, but he was not able to impress them at all. He ascertained that the Priest of the Temple of Juggernaut was the most important of these holy men, and he tried to persuade him, but at first unsuccessfully. He then repeated in a low voice the mantra he had learned years before from the Swami of Lachman Bagh. The Priest at once turned round and said: "Where did you learn that?" He told him, and the Priest asked him if he was the sahib who, when at Rewa, called himself the Chela of the Swami. On replying that he was, the Priest said: "I have heard of you; we will not go to Ujjain." And they did not. He

mentioned that as an instance of the advantage and importance of getting into touch with the people, and as showing how bread cast upon the waters in that way returned after many days.

Colonel J. M. Hunter, C.S.I. (late Political Agent in Kathiawar), thought the paper and the discussion upon it were not only of interest to the student but had a political and administrative value. The more this country knew of India and India knew of this country, the better it would be for both. There could be no doubt that a study of the language, the religion, and the customs of the people of India led to a more sympathetic administration of the country. Indian friends had often spoken to him with gratitude and appreciation of those European officers who, like the author, took the trouble to study the language and customs of the people, because they always seemed to feel that any disputes that might arise would be decided with greater justice and consideration for their feelings. He thought the Royal Society of Arts was doing a great and patriotic work by offering opportunities for the discussion of questions bearing upon the religion and manners of the people of India, because they tended to strengthen the bonds of union which already existed between the two countries. The paper gave rise to one or two very interesting reflections. In the first place, one could not fail to be struck with the shrewdness of the sages to whom reference had been made. The author had given the dignity of saints to many of them, and he supposed men who could perform such stupendous miracles as changing stone walls into chargers, tilting on the top of tigers and milking tigresses, were entitled to that dignity; in fact, the title of the paper might have been "The Sporting Saints of Pandharpur!" The so-called anchorites were really men of the world with a very shrewd knowledge of human nature, because they knew that the most successful way of rendering a cult popular was to attach it to some dominant personality such as some of the incarnations of the Hindu Triad. The next reflection that occurred to him was the extraordinary vitality and force of an ancient and popular cult like that of the Hindus. From the time of the defeat of the two leading Rajput tribes by Mahomed Ghori to the overthrow of the Mohammedan Empire by the Maratha Confederacy, a period of some 600 years elapsed, and, during that time, there was intimate social intercourse and intermarriage between the devotees of the two cults, the Mohammedan and the Hindu. Colonel Watson, in his book on the Mohammedan rule in Gujerat, said it was the custom of the Mohammedan conquerors as soon as they occupied a country to take all the young women into their zenanas, with the result that the offspring of these unions prided themselves upon being descended from the conquering race. There was no doubt that that gave the Mohammedans an extraordinary power and influence throughout the whole country. It was a remarkable thing that, although the people who held those two religions were both Orientals, and lived in the same houses under similar conditions, every distinction between the Hindus and the Mohammedans had not been obliterated. That, he thought, was explained by the fact that in spite of religious persecution the people maintained their love of their own cult. The old saying of the Pope, that "The blood of the martyrs is the seed of the Church," was no doubt illustrated in that wonderful vitality and force of an ancient and popular cult, and it was found, at the end of 600 years, that the religion was able to weld together all the different parts of the Maratha Confederacy and enable them to subvert the Mohammedan power which had lasted for that period. That gave rise to the question, What should be the attitude of a governing power towards a religion that was hostile at the beginning and no doubt dangerous for the future? It might be said that if it was not suppressed there would always be a risk of it causing rebellion; but he did not think that was so. If an ancient cult was associated with just laws, education, and prosperity, that cult became a pillar of the State instead of a danger; and he believed the Hindu religion was a pillar of the State at the present moment, because it had been treated with such perfect toleration. When St. Paul gave the injunction that the Jews were to be subject to the superior powers because they had been ordained of God, he was not founding a new doctrine; it was as old as the Vedas. That brought him to a comparison between the condition of India at the present time and the condition which existed when the Saints of Pandharpur were able to unite the Maratha nation and again restore their ancient religion and liberty. He believed there was no greater evidence of the justice of British rule than the fact that the natives of India were now fighting on our side in this great war. It was perhaps a long way to go to Bernhardi's book, but those who had read it had probably noticed that one of the reasons the author gave why the British Government had no right to its present place in the sun, nor to be the nucleus of such an immense Empire, was because the British Government had never imposed a State religion upon India. It was a good thing the Government had not done so, because if it had attempted to impose a foreign religion upon an unwilling people, would not our position have been much the same as the position of the Mohammedan Government at the time of Shivaji? One of the most remarkable and striking evidences of the contentment and attachment of the Native States to British rule came before him a few weeks ago, when he received a letter from the Maharanee of Bhavnagar, in which she said: "I hope you will accept the bound volume which I am sending you by post of a year's publications of my weekly newspaper, which I have been editing myself, the object of which is to refute all the abominable falsehoods which are being perpetrated and spread all over India by the Germans." It was impossible to have a more striking tribute than that; and in

spite of those who were detractors of British rule in India, he believed this country could look back upon the past history of the administration of India with pardonable feelings of pride, and look forward with confident hope to a greater and happier future for that interesting country as a member of our great Empire.

SIR H. EVAN M. JAMES, K.C.I.E., C.S.I., said he was afraid he could not follow the author in all the excellent results which he thought flowed from the existence of the poetical saints referred to in the paper. He did not quite understand whether the author meant to convey that the Marathas were made a strong nation and able to defend themselves against proselytising Mohammedans, or whether he merely meant that the saints made the Hindu religion more popular than Islam. If he meant the former, with great deference he disagreed with him, because the Mohammedans were never a great proselytising race in India. They were usually tender towards the conquered Hindus and even around the Mogul capitals the proportion of Mohammedans was quite small. They were inconoclasts, of course, like the Puritans in England. He also could not quite follow the author's statement that the poets made Pandharpur a literary centre. As a matter of fact, there was no Maratha literature in those days, and even the great Shivaji could not write his own name. It was possible that some of the poems might have influenced the language of literary people at a later period, in the same way as Chaucer was supposed to have affected the English language; but otherwise he could hardly see that Pandharpur was ever more than a religious centre, and a very popular place of pilgrimage.

MR. J. S. COTTON said, that though he had never been on pilgrimage to Pandharpur, nor could even claim to know the Marathi language, he might venture to contribute to the discussion from a fresh point of view. Among the MSS. collected by Colonel Colin Mackenzie a hundred years ago, most of which were now in the library of the India Office, there were at least three relating to Pandharpur. Two of them are Sthala Mahatmyas, or Legends of the Holy Place, one in Marathi and the other in Telugu. The latter was of special interest in connection with the temple of Vithoba at Vijayanagar, to which he would refer again, for Telugu was the vernacular of the Rayals (or Rajas) of that place, though not of the people. In addition, there was an English translation (Vol. XIV. No. 17) of a Marathi account of Pandharpur, its legends and its temples, in considerable detail, which had been taken down on the spot in 1807. There was, first, the story of the eponym of the place, Pandlik, here called Pandarika, a name with a Kanarese termination. He was a Brahman so famed for filial piety that the god Krishna came all the way from Dwarka to visit him. Instead of attending to the god, he was so absorbed in his duties to his parents that he only gave the god a brick to sit upon; and to this day the image of Vithoba stands on a brick, *ita* = "brick" in Marathi, from which his name is traditionally derived. Afterwards, Rukhmini, the consort of Krishna at Dwarka, in despair at the long absence of her husband, came in search of him, and there she now stood by his side. It was evident, therefore, that the incarnation of Vishnu worshipped at Pandharpur is not Rama, or even the Krishna of Muttra, but the Krishna of Dwarka. Another story here told was worthy of mention. Perhaps the only temple of Vithoba to be found in the South of India is a magnificent building still standing among the ruins of Vijayanagar, which had never been completely finished, and contained no image of the god. The story there told (*Bellary Gazetteer*, p. 276) is that Vithoba had been conveyed thither from Pandharpur by the Rayal, but that he had found the place too grand for him and preferred to return to his own humble home. At Pandharpur the same story is told somewhat differently. One of his devotees followed him all the way to Vijayanagar, where the god, in response to his fervent entreaties, transformed himself into his Dwarf incarnation as Vaman, so that he could conveniently be carried back. The speaker concluded with some arguments indicating that Vithoba, though not now worshipped in the Kanarese country, may originally have been a Kanarese deity. Bhagwanlal Indraji (*Sholapur Gazetteer*) agreed with Sir R. Bhandarkar that "Vithal" was a Kanarese corruption of "Vishnu." The same authority stated that the oldest inscription in the temple, dated in the thirteenth century, contained two place-names each with a Kanarese termination, one of which was Pandarika, mentioned above. He had since noticed that Sir G. Grierson, in his chapter on Vernacular Literature in the *Imperial Gazetteer* (II. 425), mentions a Krishna poet named Vithala-natha, who wrote in Kanarese. All this tended to show—what there were other grounds for believing—that the linguistic boundary between Kanarese and Marathi formerly extended some distance further north than at present up the course of the Bhima River.

SIR FREDERIC S. P. LELY, K.C.I.E., C.S.I., in proposing a hearty vote of thanks to the author of the paper, said his only regret was that he did not hear it fifty years ago, because then he would have been equipped with a great deal of useful information which he had not obtained until the present moment. Nothing gripped the heart of the ordinary native of India so much as the discovery that his companion knew something about his heroes and saints, names which were household words in the family. The Indians were a nation of mystics; they lived in a supernatural atmosphere, which was always present with them. The stories which the author had narrated possessed for English people a philosophical interest, but to the natives of India they were gospel stories. He desired to mention one instance which showed how intensely present the supernatural was to the natives, and that the age of miracles was not by

any means past in India. Some years ago he noticed, when passing through a village in India, a temple which, from the newness of the masonry, showed that it had only just recently been built. He inquired of the local official why the temple had been built, and was told that it was because of a miracle that had occurred in the village two months previously, when the village cattle were coming back from pasture one evening and the earth opened and swallowed one of them. A temple was built in honour of its memory, and an image of a cow was placed in it. Personally he had no doubt that the little rascal who had charge of the cattle knew more about it than that; probably he had lost the cow, and invented the story to account for its absence.

Sir Mancherjee M. Bhownaggree, K.C.I.E., in seconding the motion, said the paper would appeal very strongly to the mind of the people of India. A very widespread impression existed among many classes there that the English administrator did not so fully sympathise or enter into the lives and habits of the people as was desirable, and that he was always more or less of a stranger to them. The late Mr. Alexander Rogers, whose name was known to many present, and who, like Mr. Kincaid, belonged to the Civil Service in Bombay, after forty years' study of Persian and Oriental literature, rendered many of the works in those languages into English, and it was his (the speaker's) great pleasure a few years ago to co-operate with Mr. Rogers in publishing, for the benefit of the English-reading public both in this country and in India, some of those productions. He desired to emphasize the remark made by the Chairman and other speakers that such instances of the sympathetic study of the language and people of India on the part of European friends and officers carried the conviction to the minds of the people that both their history and mode of life appealed to their consideration and formed a serious subject of study.

The resolution was carried unanimously.

Mr. C. A. Kincaid, in reply, said that Sir Evan James had said he could not understand why he (the author) thought it was a good thing the Marathas did not become Mohammedans. That depended upon the way in which the subject was looked at. Personally, he approached the paper from the Maratha point of view, and he thought that if he was a Maratha he would prefer to remain so, as an Englishman preferred to be an Englishman rather than become the subject of any other government.

TWELFTH ORDINARY MEETING.

Wednesday, March 1st, 1916; George Granville Leveson-Gower in the chair.

The following candidates were balloted for and duly elected Fellows of the Society:—

Barneson, Captain John, 310, Sansome-street, San Francisco, California, U.S.A.

Parrish, Samuel L., Southampton, Long Island, New York, U.S.A.

Sadd, W. A., Chattanooga Savings Bank, Chattanooga, Tennessee, U.S.A.

Tabor, Joseph Matthew, Peninsular House, Monument-street, E.C.

The paper read was—

MAETERLINCK, VERHAEREN ET LES LETTRES BELGES.

By M. Charles Delchevalerie.

La petite nation belge, qui a grandi dans l'estime universelle, dès le début de la guerre, en s'illustrant par la défense de son honneur contre un adversaire dont elle n'ignorait pas la force, cette petite nation que l'Angleterre s'est si magnifiquement appliquée à secourir dans son immense infortune, avait déjà, avant la tourmente, conquis un noble rang, par le mérite et l'initiative de ses enfants, dans la famille européenne. Elle avait, vous le savez, produit des savants éminents, des hommes d'action, des hauts artistes. Et pourtant, au cours des âges, il y a dans ses annales plus de douleur encore que de gloire. Sa situation géographique a fait de son sol un perpétuel champ de bataille où les rivalités des princes et des peuples venaient vider leurs différends.

De Jules César à Charles le Téméraire, de Philippe le Bel de France à Philippe II d'Espagne, de Louis XIV à Napoléon, ce qui devait devenir la Belgique fut une mosaïque changeante de provinces morcelées, passant de siècle en siècle sous des dominations successives. Et cependant, les cruels bouleversements de l'histoire n'ont pas empêché les races jumelles attachées aux rives de l'Escaut et de la Meuse, la Flamande et la Wallonne, d'affirmer leur vigueur et leur volonté de progrès par la valeur et l'éclat des individualités auxquelles elles ont donné la vie.

Nous sommes ici dans la sereine Maison de l'Art. En ces jours, où le réveil de la barbarie agressive a déchaîné sur le vieux monde les aventures de la violence, il est réconfortant d'y pouvoir évoquer, pour l'honneur de cette petite nation qui reste la plus touchante victime du grand drame, la beauté du culte de l'idéal, la grandeur de ce qui ne peut mourir. Les Huns ont pu déchirer et mutiler la Belgique, ils ne lui enlèveront pas sa couronne. Ils n'ont pu que la faire briller d'une plus pure clarté en permettant qu'on y ajoutât les joyaux d'un nouvel héroïsme.

Ses gloires artistiques, dans le domaine de la peinture et de la sculpture, vous les connaissez

depuis longtemps, et l'an dernier, à cette même tribune, l'érudit critique d'art qu'est M. Paul Lambotte vous en a excellemment rappelé l'opulence et la diversité. Depuis quelque trente années, le patrimoine intellectuel de la Belgique s'est enrichi d'un autre trésor, et c'est de celui-là qu'à mon tour je voudrais, de mon mieux, signaler quelques unes des merveilles, à la faveur de ce bref entretien.

La récente floraison de la littérature de langue française en Belgique est un admirable et surprenant phénomène, qui mérite de retenir l'attention de tous les lettrés du dehors. Il a d'ailleurs, jusqu'en ces derniers mois, provoqué l'éclosion d'un grand nombre d'études critiques, et l'une des dernières, due à un savant professeur anglais, M. Jethro Bithell, est un modèle d'analyse consciencieuse, compréhensive et sympathique.

Avant 1880, on peut dire que la littérature originale était chez nous presque inexistante. Sans doute, en des temps lointains, les grands chroniqueurs Froissart et Comines naissent sur le sol belge; belge est aussi, par l'origine, ce grand Européen du dix-huitième siècle qui s'appelle le prince de Ligne. Ce sont là des prodiges isolés, des monstres indépendants du milieu où le hasard les fait surgir.

Au dix-neuvième siècle il faut à la Belgique cinquante ans de vie nationale indépendante pour que, dans les limbes où s'évertuent de ternes polygraphes, s'éveille une conscience littéraire enfin vigoureuse et personnelle. Aussi bien, dans un effroyable désert d'indifférence, quel héroïsme ne faut-il pas pour tenter le vain effort d'émouvoir l'improbable lecteur par la vertu des vers ou de la prose! Deux vrais écrivains se manifestent seuls avant 1880: un Wallon, Octave Pirmez, aristocratique rêveur qui distille dans la solitude ses pensées hautaines et mélancoliques, et le visionnaire opulent et pathétique de la "Légende d'Ulenspiegel," Charles de Coster, né à Munich de parents belges. Celui-ci, dans un livre épique et frémissant, retrace, autour d'une figure de héros populaire et familier, le douloureux tableau de l'histoire des Provinces Unies sous la sombre tyrannie religieuse des Espagnols au seizième siècle, et il y a dans son récit toute la ferveur d'un acte de foi patriotique.

Tout à coup, c'est une éclosion spontanée de talents et d'enthousiasmes, comme si la jeune nation, ravie de la prospérité de ses labeurs, voulait extérioriser son allégresse en s'assurant de nouveaux triomphes dans les hautes régions de l'esprit. Disons-le tout de suite, cette révélation d'une élite ne trouve nullement dans le public l'écho auquel elle pouvait s'attendre. Longtemps encore, poètes et prosateurs devront se contenter des suffrages d'un cercle restreint. Mais la confiance est née. Il y a quelque chose de changé. Les écrivains, pleins d'une ardeur juvénile, se sont groupés autour d'un aîné qui est déjà un maître, et qui est un magnifique professeur d'énergie, Camille Lemonnier. Ils ont fondé une revue qui s'appelle la *Jeune Belgique*—titre emblématique!—et d'où vont sortir ceux qui ont aujourd'hui conquis la gloire à l'étranger. C'est l'aurore qui se lève, radieuse, après la longue nuit sans espérance.

Cet éveil d'une cohorte qui va compter bientôt ses batailles et ses victoires mériterait d'être longuement évoqué, car il fut profondément intéressant, mais il faut savoir se borner. Faute de pouvoir dignement parler de tout le monde, nous envisagerons, si vous voulez, nos lettres belges de l'extérieur, en considérant spécialement leurs unités les plus notoires et les plus représentatives, celles dont la renommée a nettement franchi les frontières.

* * * * *

Dès lors, il est un nom qui s'impose avant tous les autres, c'est celui de Maurice Maeterlinck, célèbre à Moscou comme à Paris, à Rome comme à Londres, lauréat du prix Nobel, interprète éminent de la pensée européenne. C'est en 1885 que la revue la *Jeune Belgique* révèle pour la première fois son nom au public, dans un article du poète Georges Rodenbach, et qui signalait, en même temps que Maeterlinck, deux autres poètes, ses amis, tous deux Gantois comme lui, Charles Van Lerberghe et Grégoire le Roy. Unis dès le collège, ils fréquentaient à cette époque les cénacles parisiens, et Maeterlinck venait de s'y faire connaître en publiant un long poème en prose, "Le Massacre des Innocents," qui est la saisissante transposition d'un tableau de Breughel. Il avait aussi composé un recueil de vers étranges: "Serres Chaudes."

Son théâtre de la première manière, son théâtre de mystère, est en germe dans ce livre, où il note avec d'étonnantes images, subtiles et inattendues, qui attestent une sensibilité aussi fine qu'opulente, le malaise des discordances sentimentales. Ce symbolisme impressionné par l'étude des grands écrivains mystiques, ces conflits silencieux de l'âme et de la destinée, sont la matière de son livre d'essais, de cet admirable "Trésor des Humbles" que vous connaissez tous, et font l'argument de ces petits drames "pour marionnettes," comme il les appelait modestement, qui apportèrent sur les

planches l'émotion d'un "frisson nouveau." La première de ces pièces légendaires, la "Princesse Maleine," paraît vers 1889, imprimée à quelques exemplaires, pour les amis de l'auteur. Mais l'un d'eux veillait, c'était Octave Mirbeau, le grand romancier paroxyste. Dans un retentissant article du *Figaro*, il annonce au monde la naissance d'un nouveau Shakespeare. Éloge terrible, sous lequel un médiocre eut pu rester à jamais enseveli, mais Maeterlinck, dont l'humilité avait été soumise à une épreuve aussi imprévue, n'était heureusement pas un médiocre. Après la "Princesse Maleine," qui est l'un des plus rudimentaires de ses drames, il sut s'amplifier magnifiquement, se diversifier et s'approfondir en écrivant "L'Intruse," et "Intérieur," où le symbole de la mort surgit avec tant de simplicité dans la puissance, et ces poèmes merveilleux de tendresse et de terreur qui s'intitulent "Pelléas et Mélisande," "Aglavaine et Selysette," "La Mort de Tintagiles."

On y trouve des cris d'un lyrisme Shakespearien ; on y trouve surtout une philosophie nouvelle du monde, à la fois mystique et réaliste, et dans les aventures sommaires de ses héros instinctifs, dans leur plainte souvent monocorde, dans leurs tâtonnements guidés par la vacillante lueur du pressentiment, l'émoi provient de je ne sais quelles vérités éternelles dont on voit transparaître le visage.

Ce théâtre angoissant et sybillin, M. Remy de Gourmont le définissait jadis ainsi : "Il y a une île quelquepart dans les brouillards, et dans l'île il y a un château, et dans le château il y a une grande salle éclairée d'une petite lampe, et dans la grande salle il y a des gens qui attendent. Ils attendent quoi ? Ils ne savent pas. Ils attendent que l'on frappe à la porte, ils attendent que la lampe s'éteigne, ils attendent la Peur, ils attendent la Mort. Ils parlent ; oui, ils disent des mots qui troublent un instant le silence, puis ils écoutent encore, laissant leurs phrases inachevées et leurs gestes interrompus. Ils écoutent, ils attendent. Elle ne viendra peut-être pas ? Oh ! elle viendra. Elle vient toujours. Il est tard, elle ne viendra peut-être que demain. Et les gens assemblés dans la grande salle sous la petite lampe se mettent à sourire et ils vont espérer. On frappe. Et c'est tout : c'est toute une vie, et c'est toute la vie."

"On peut dire," ajoute autre part le même éminent critique, "que Maeterlinck a renouvelé la vie, notre façon de sentir la vie. Il y a découvert toutes sortes de petits ruisseaux dont est fait le grand fleuve, toutes sortes de richesses ignorées dont il nous a appris à jouir, avant qu'elles aillent se perdre dans le courant de l'inconscience. Il y a une manière de regarder une rose qui meurt ou de regarder une vieille femme qui prie à l'église, une manière de découvrir de la poésie dans les actes les plus humbles et les plus coutumiers, une manière d'interpréter la vie, toutes les manifestations de la vie, qui n'étaient pas possibles avant lui. Il a multiplié en nous les motifs d'émotion, il nous a appris à chercher la signification de tout, à communier avec tout ce qui a vie ou mouvement et, encore que cette méthode puisse conduire à la sensiblerie et à la préciosité sentimentale, il n'y est pas tombé."

Maeterlinck, en enrichissant notre sensibilité, a contribué de la façon la plus bienfaisante à éclairer la morale moderne, et c'est ce rôle d'éveilleur des consciences qui lui a valu sa légitime gloire universelle. Aussi bien, il a évolué bientôt. Le dramaturge et l'essayiste ont, dans l'observation de la vie, dans l'étude de la nature, dans la méditation, vu s'éclairer leur conception du monde. C'est sous une lumière croissante de confiance et d'optimisme que le lyrisme de Maeterlinck s'exalte dans les évangiles harmonieux qui se succèdent sous ces titres : "La Sagesse et la Destinée," "Le Double Jardin," "Le Temple Enseveli," dans les fables dramatiques de "Monna Vanna," de "Joyzelle" et de cette noble et pénétrante féerie de "L'Oiseau Bleu," qui fut prestigieusement représentée à Londres, et aussi dans les prodiges de compréhension attendrie et profonde que sont "La Vie des Abeilles" et "L'Intelligence des Fleurs." Que la plus claire sagesse soit d'avoir foi dans la grandeur humaine, dans la mystérieuse ascension vers un meilleur devenir, c'est la leçon de ces livres qui célèbrent la santé morale, la bonté et l'énergie. Ils sont, dans leur sérénité lumineuse, très distants de l'angoisse et du repliement du Maeterlinck des débuts, et l'on a critiqué parfois les solutions d'espérance que le penseur en ses pages récentes propose aux vieux problèmes. On a parlé d'optimisme facile, d'éthique adaptée aux besoins des gens du monde. Quoi qu'on veuille conclure de cette controverse, l'auteur de "Monna Vanna" n'en reste pas moins un des guides les plus clairvoyants de l'intellectualité contemporaine, un des plus miraculeux virtuoses de l'art d'écrire, un des hommes qui, sur le chaos des idées et sur le malaise des morales, ont projeté les rayons les plus sûrs et les plus consolants.

* * * * *

Un autre grand Belge a suivi une courbe correspondante, et il est, lui aussi, honoré désormais, partout où il y a des êtres qui pensent, de l'admiration de l'élite. C'est un poète, c'est le grand poète Émile Verhaeren. Plus âgé que Maeterlinck, il naît aux environs d'Anvers, et nous le trouvons au premier rang quand se lèvent les milices de la *Jeune Belgique;* c'est alors qu'il publie son premier recueil de poèmes, "Les Flamandes," livre enthousiaste, sensuel, débordant, où le patriotisme de la race éclate en couleurs violentes, avec toutes les exubérances d'un culte fanatique. Déjà, sous une forme volontiers brutale et rocailleuse, se marque la puissance du poète, son souffle épique, sa virile envolée, qui le classent dans la famille des grands lyriques. Après avoir chanté amoureusement les prestiges matériels de son pays, il a un retour vers le mysticisme. L'ascétisme et ses rudesses, les rigueurs de la discipline monastique, lui inspirent les poèmes des "Moines," où, quand, par exemple, apostrophant ses héros, il les appelle

Prêcheurs tenant levés vos bras à longues manches
Sur les remords ployés des peuples à genoux,

il aligne des images d'une largeur épique dont on ne trouve guère d'exemple que chez Victor Hugo. Et voici que la crise s'accentue. Trois livres se suivent: "Les Soirs," "Les Débâcles," "Les Flambeaux noirs," qui sont certes parmi les cantiques les plus farouchement désespérés qu'ait exhalés la détresse humaine. C'est la plainte d'une âme malade et qui doute, qui se replie et qui saigne. Une atmosphère de deuil et de néant plane sur ce chant solitaire, qui évoque l'horreur de l'être perdu dans les effrois de l'hiver et de la nuit, dans le silence des étendues indifférentes, dans l'hostilité glacée des ténèbres qui ne s'éclaireront pas. La folie est au bout d'un tel soliloque.

Heureusement la crise ne dure pas. Dans le ciel orageux, un rayon finit par luire, présage des hautes clartés futures, et cette promesse du retour à la lumière s'appelle les "Apparus dans mes Chemins." Cependant, le poète a cessé d'analyser sa maladie et sa douleur personnelles. Il s'est tourné vers le monde extérieur. Il y a trouvé, dans le drame social ambiant, des thèmes pathétiques nouveaux. L'exode des villageois vers les cités, la misère des bourgades de Flandre, les symboles éternels qu'un grand inspiré peut tirer du spectacle des images traditionnelles et familières, donnent naissance à ces recueils caractéristiques, que nul autre n'aurait pu écrire, et qu'emplit le souffle fraternel d'une charité véhémente: "Les Villes Tentaculaires," "Les Campagnes Hallucinées," "Les Villages Illusoires." Désormais, le spectacle du monde va, dans l'âme de ce grand visionnaire, se résoudre, comme chez Maeterlinck, en paraboles de confiance et d'énergie. Les puissances qui régissent l'effort humain, les Lois, les Vérités en devenir, l'Harmonie vers laquelle tend éperdument le labeur obstiné des générations, hantent sa pensée, animent ses poèmes démesurés. Ils sont pleins d'une ferveur enivrée. "Les Forces Tumultueuses," "Les Visages de la Vie," "La Multiple Splendeur," "Les Rythmes Souverains," voilà les titres de ces livres où s'exalte l'allégresse de penser et de croire, où l'univers de l'esprit et de la matière se meut selon le rythme du plus généreux espoir. Il semble que par instants, dans ces strophes palpitantes, on sente l'âme même de la vieille Europe se hausser vers les horizons radieux.

La vie est à monter, et non pas à descendre,

s'écrie-t-il, et ailleurs encore, en vingt vers comme celui-ci:

Vivre, c'est prendre et se donner avec liesse!

cet apôtre de la plus haute solidarité humaine formule le réconfortant crédo de son âme apaisée, et que chaque matin nouveau, semble-t-il, rend plus juvénile et plus résolument enthousiaste.

De tels hommes sont des bienfaiteurs parcequ'ils exaltent magnifiquement la beauté de l'existence et donnent au plus humble conscience de la noblesse de son obscurité. Comme Maeterlinck, Verhaeren devait trouver, pour flétrir les sauvages auteurs de la guerre actuelle, des accents d'une exceptionnelle éloquence, et les poèmes indignés dans lesquels il a célébré le deuil de la patrie innocente sont parmi les pages les plus émouvantes que l'affreuse tragédie ait inspirées.

Aussi bien, Verhaeren n'avait pas attendu la tourmente pour proclamer avec la ferveur touchante et têtue de sa race sa religion du sol natal. On l'a vu, son ouvrage de début est un cantique chaleureux à la gloire des Flandres. L'image de la petite patrie transparait dans presque tous ses livres. Et depuis quelques anneés, ce sentiment filial l'a hanté au point qu'il a commencé la publication d'une série de cahiers à la louange de la terre des ancêtres. Déjà plusieurs recueils de cette suite ont paru, sous ce titre général: "Toute la Flandre." Tous les prestiges du passé, héroïque ou familier, déroulent dans l'âme du grand poète une fresque somptueuse et pathétique. Comme les malheurs de la Belgique ont dû retentir profondément en lui, et comme il était qualifié pour s'agenouiller

devant la divine meurtrie quand, dans un de ses récents poèmes il la salue de ce vers poignant :

Tu te grandis si haut que tu es solitaire !

Écho frémissant des émois et des espoirs de l'époque, miroir plus intime de la terre des aïeux, le talent de Verhaeren a prouvé une autre maîtrise encore quand, dans les poèmes confidentiels de ses "Heures claires," il a célébré, dans l'effusion, dans la sérénité ravie, la secrète et lumineuse exaltation du bonheur domestique. Pour dire la joie loyale et durable d'aimer et d'être aimé, ce violent, cet impulsif a rimé les strophes les plus délicates, les plus gravement attendries, et ce recueil d'intimité est parmi les plus purs chefs-d'œuvre, les plus sobres et les plus noblement inspirés dont se soit enrichie la poésie du sentiment.

* * * * *

Un des critiques avertis de nos mœurs, M. Dumont-Wilden, a jadis appelé la Belgique le pays des marchands. Par esprit de réaction sans doute—et c'est chose curieuse à constater—la littérature de ce peuple positif est surtout abondante en poètes. Poètes, et grands poètes, les deux écrivains de génie reconnu dont je viens d'essayer d'esquisser la silhouette. Ces deux-là nous représentent devant l'universalité des lettrés ; vingt autres moins illustres, dont je voudrais cependant citer au moins les noms, dans une très brève revue, mériteraient de retenir longuement votre curiosité par la profonde et sincère originalité de leur inspiration. Rien de plus varié que le bouquet de leurs poèmes ; chacun colore son lyrisme des nuances de sa sensibilité. J'ai nommé tout à l'heure Georges Rodenbach. Singulière destinée que celle de ce chantre du regret qui, vivant dans le tumulte de Paris, y reste fidèle au souvenir des béguinages flamands, y demeure le nostalgique et tenace évocateur de Bruges la morte, de ses canaux léthargiques où les cygnes en silence voguent sur l'eau verdie, dans le miroitement du ciel paisible. Un doux lyrisme visionnaire, précieux et dolent, caractérise, dans ses nouvelles et ses vers, les symphonies atténuées, un peu monotones, où se complaît sa muse amoureuse de la solitude et du crépuscule. Ses livres ont au surplus des titres emblématiques, ils s'intitulent "Le Règne du Silence," "L'Art en exil," "Musée de Béguines," "Les Vies Encloses," "Le Rouet des Brumes," "Le Miroir du Ciel Natal." Avec un talent très personnel, en des chansons dont la musique amortie rappelle le ronron du rouet des vieilles fileuses, Grégoire le Roy s'apparente, comme Rodenbach, à la famille des grands nostalgiques. Georges Marlow est, lui aussi, un harmoniste de la même phalange, cependant qu'Albert Giraud, plus classique, en des strophes qui unissent la netteté des médailles antiques à la somptuosité de coloris des maîtres flamands, proclame d'une âme plus virile et plus hautaine son dédain du présent et son lancinant regret des grandes époques où pour lui "l'action était la sœur du rêve." A côté des virtuoses de la nuance, il représente un art de décor et de perfection plastique d'une rare noblesse, et dont l'émotion est si secrète qu'elle n'est pas souvent apparente.

Ces poètes, comme le délicieux enlumineur Max Elskamp, qui recrée dans ses poèmes la naïveté archaïque de l'imagerie et de la chanson populaires, se réfugient dans le mirage des temps disparus. Il en est d'autres, parmi les meilleurs, qui se sont créé un univers à eux, rayonnant, féerique, irréel, dans lequel les fantômes issus de leur pensée miment les épisodes du drame éternel. Leur humanité est à la fois légendaire et contemporaine. Au premier rang de ces magiciens on peut certes classer le regretté Charles Van Lerberghe, en qui Maeterlinck salua jadis le maître affectueux et sûr de son inspiration dans le domaine dramatique. Il n'est pas d'atmosphère plus fluide et plus suavement lumineuse que celle de ses poèmes. Dans ses "Entrevisions" et dans sa "Chanson d'Ève," il ressuscite en vérité la jeunesse de la terre en faisant surgir, dans la splendeur d'une aube surnaturelle, des visions dont la simple grâce et la pureté enfantine évoquent la beauté des chefs-d'œuvre florentins. Chacune des claires pages qu'on doit à ce roi d'un monde émerveillé donne au lecteur la joie de la perfection réalisée.

Le Wallon Fernand Severin nous la donne aussi, cette impression, dans les strophes fières et confidentielles, de forme toute racinienne, de ces recueils qui attestent son tempérament d'intimiste fervent : "Un Chant dans l'Ombre," "Le Don d'Enfance," "La Solitude Heureuse." Ce "Don d'Enfance" qu'il célèbre religieusement, c'est celui du poète, qui garde devant la beauté du monde la pureté d'un regard ingénu, d'une effusion toujours candide et généreuse. Pour dire l'accent profond de ses extases, il trouve des harmonies d'une ineffable délicatesse.

Tandis que la *Jeune Belgique* paraissait à Bruxelles, une autre revue qui fit également époque naissait à Liège, la *Wallonie*, sous l'impulsion d'Albert Mockel. Critique d'une pénétration rare, celui-ci est aussi parmi les plus nobles de nos poètes, et ses "Contes pour les Enfants d'Hier" revêtent d'une lumière enchantée des fables pleines de symboles héroïques et gracieux. Du poète Isi Collin on a représenté

l'an dernier à Londres une délicieuse parabole, "Sisyphe et le Juif Errant," qui a fait connaître aux lettrés anglais le talent de cet heureux évocateur de visions païennes. Ivan Gilkin composa jadis de vigoureux poèmes pessimistes dans la manière baudelairienne. Paul Gérardy montre dans ses "Roseaux" la verve d'un ingénieux trouvère, et Louis Delacre a noté de façon subtile et délicate les sensations de la vie provinciale. . . .

* * * * *

Mais on ne peut, hélas ! citer tout le monde. . . Ceux dont j'ai parlé sont surtout des rimeurs. Mais, répétons-le, en ce curieux pays, les prosateurs, romanciers et conteurs ont aussi, pour la plupart, des tempéraments de poètes.

Tel est certes le cas de celui qui fut leur maître à tous, au moins par l'énergie et la ferveur de l'exemple, Camille Lemonnier. L'un des premiers livres qui lui assurent la notoriété est un frémissant cahier d'impressions qu'il avait recueillies sur le champ de bataille de Sedan, "Les Charniers." C'est le moment, hélas, de rappeler que Maupassant salua cet ouvrage comme l'un des plus éloquents qui aient flétri les horreurs de la guerre. Mais comment passer sous silence l'effort d'un Lemonnier ? Quarante ans d'écriture, soixante volumes amassés, des batailles et des victoires, une vie vaillamment dépensée à combattre pour le beau et le vrai, au milieu de l'indifférence : cette vie même est une œuvre de constance et de loyauté. Actuels ou situés hors du temps, ses romans et ses contes sont des récits de poète merveilleusement descriptif plutôt que des travaux d'analyste. Lemonnier a le culte enthousiaste de la vie, elle le requiert sous tous ses aspects ; après avoir évoqué l'humanité rustique dans "Un Mâle" et "Le Mort," il écrira des évangiles légendaires comme "Adam et Ève" et "Au Cœur frais de la Forêt," ou il étudiera des psychologies plus complexes dans "L'Arche," dans "Le Possédé," dans "L'Hallali" ; il s'élèvera dans "Ceux de la Glèbe" et dans ses "Noëls Flamands" au rang des plus prestigieux conteurs. Tantôt l'intimité le tente, et tantôt la grande fresque sociale ; ses récits s'inspirent délicieusement de la poésie du milieu ; tantôt il nous place dans le décor discret de la petite ville flamande aux pignons dentelés, et tantôt dans la fraîcheur transparente des matins sur la Meuse, tandis que sur la colline le soleil montant dénoue les écharpes du brouillard.

Écrivain puissant, abondant, enthousiaste, il a dressé un monument à la beauté de la patrie en la décrivant dans les huit cents grandes pages de sa "Belgique" et il en a exalté les gloires artistiques en de nombreuses monographies qui attestent une exceptionnelle richesse de compréhension.

Autour de cet aîné si valeureux, qui mourut il y a peu d'années sans avoir jamais défailli dans l'épreuve, voici une légion de conteurs, qui ont entassé des livres parfumés de l'odeur du pays. De fait, il y a peu d'exemples chez nous d'écrivains indifférents au décor qui les entoure. Chacun se rattache à sa contrée. C'est dans la région flamande Georges Elkhoud qui, avec une force et une émotion fraternelle qui rappellent Gorki, se penche sur les irréguliers, sur les errants de la lande anversoise ; c'est Georges Virrès qui nous situe dans les villages de Campine, et Léopold Courouble dont l'humour retrace les mœurs de la petite bourgeoisie bruxelloise. En Wallonie, Maurice des Ombiaux et Louis Delattre se partagent leur Hainaut familier en des récits joyeux, où se reflète la santé morale d'un peuple honnête et laborieux ; c'est Edmond Glesener, vigoureux ironiste, le mieux doué peut-être pour l'envergure du roman ; c'est Hubert Krains, qui note avec la pointe dure d'un aquafortiste la pénible vie des paysans de Hesbaye, et Georges Garnir, sentimental et souriant. . . . Chacun est roi de son petit domaine ; chacun a si bien parlé de sa terre qu'il nous l'a fait aimer davantage ; chacun a sacrifié sans préméditation au meilleur patriotisme.

* * * * *

Veuillez excuser, mesdames et messieurs, toutes les lacunes de ce résumé, à la fois trop long et trop court, dans lequel, par simple souci de justice, j'eusse dû faire rentrer bien d'autres noms encore, et de considérables, comme ceux d'Eugéne Demolder, qui retrouve la saveur des peintres de Hollande pour en aviver l'attrait de ses nouvelles fleuries, et d'Edmond Picard, qui a donné tant de vie à ses scènes du monde judiciaire.

Mais tout ne peut se dire en une heure. J'ai voulu simplement signaler à ceux qui pourraient l'ignorer, combien depuis un quart de siècle notre Belgique s'est illustrée dans les hautes régions de la pensée et de la sensibilité par l'éclat de sa renaissance littéraire. Elle représente maintenant, dans les lettres françaises, une des provinces les plus riches et les plus fécondes. Et, vous me permettrez de le faire remarquer, ce qui distingue nos écrivains, c'est la sincérité désintéressée, le courage silencieux de leur effort. L'indifférence du public, orienté vers la production étrangère, a fait qu'en dehors

du journalisme on ne peut chez nous vivre des travaux de la plume, si bien que l'écrivain professionnel y représente une espèce humaine à peu près complètement inconnue. Les poètes et les prosateurs y sont cependant nombreux, tout comme s'ils étaient encouragés ; ils travaillent dans le loisir que leur laisse une autre profession plus lucrative, ils écrivent pour satisfaire un besoin de leur être pensant et sensible, ils écrivent parce qu'ils ont quelque chose à exprimer.

Ce fait qu'ils n'ont guère eu à espérer jusqu'ici que les suffrages d'une élite restreinte est pénible à constater, mais il faut reconnaître que de la volonté des écrivains, exempte de toute avilissante idée de commerce, de toute courtisanerie à l'égard de la foule, ne peuvent naître que des œuvres singulièrement honnêtes et nobles. L'effort gagne souvent en dignité ce qu'il perd en profit. Il est loyal et solitaire, il puise sa force en lui-même, et ne se presse pas pour produire des œuvres hâtives et mal méditées.

Chacun chantant pour sa propre joie intime, exalte ainsi les meilleurs dons de sa race. La fastueuse imagination flamande, l'ironique et tendre sensibilité wallonne, fleurissent miraculeusement et durablement dans les contes et les poèmes, après avoir triomphé dans les tableaux et dans les musiques. Il y a pour l'observateur sympathique une source d'émotion pénétrante dans le spectacle de la ferveur filiale avec laquelle nos littérateurs, à chaque page et presque inconsciemment, magnifient les prestiges de la petite patrie et la douceur de vivre sous son ciel. C'est un hommage permanent, un cantique perpétuel. C'est dans leurs pages la saine odeur du pays natal qu'on respire : il n'est pas un d'eux qui ne soit imprégné de cette piété jusque dans les fibres les plus secrètes de son être. Et de la sorte, en chantant leur pays avec tant d'amour, ils l'ont fait mieux connaître et mieux aimer encore. Ils ont, par le miracle de leur intuition attentive, exprimé les mille raisons que nous avons de chérir la terre des ancêtres. Ils l'ont glorifiée dans le temps et dans l'espace. Ils ont dit la clarté changeante de ses jours paisibles, la grâce de ses collines, la sérénité de ses plaines, le sourire de ses rivières, la bonhomie, la vaillance tranquille, la stoïque volonté d'indépendance de son vieux peuple loyal et infatigable. Ils ont puisé de la beauté profonde et durable à l'humble source des émotions familières. Ils ont ainsi, parce qu'ils ont eu raison de chanter, conquis des provinces idéales, à jamais inaccessibles aux ravages de l'agresseur. Ils ont rendu plus précis, plus gracieux et plus touchant le cher fantôme qui là-bas, sur la terre meurtrie, palpite dans les plis des drapeaux déchirés. Laissez-moi les saluer en terminant, leur dédier un peu de la gratitude du peuple dont ils ont enrichi le plus noble patrimoine. Grâce à eux, on sait comment chez nous, de quelle façon pieuse, enthousiaste et tenace, l'attachement au sol natal s'exprimait dans la sécurité joyeuse, avant d'être, par les surprises du malheur collectif, stimulé jusqu'aux plus beaux sursauts de l'héroïsme.

The Chairman (George Granville Leveson-Gower), in proposing a hearty vote of thanks to the author for his interesting paper, said he thought he was rightly interpreting the feelings of those present in saying how much they had appreciated the lucid, forcible, eloquent, and deeply touching manner in which the author had fulfilled his task that afternoon. He had touched upon one or two points which were extremely interesting, and would well repay further consideration and amplification. One striking point was the quality and character of the various writers whom the author had so eloquently described. Some of those writers were known to those present before, and they would probably study them all with increased interest after having heard the paper that afternoon, in which the author had touched on the wide and varied store of riches in Belgian literature of modern times. It occurred to him that possibly the deep love of country, the mixture of tender mysticism and ardent patriotism, and the wide view of human life and human thought manifested by the writers mentioned, might have arisen in the strange and touching vicissitudes which Belgium had undergone, not only recently but in the past also. Many of those present probably knew the deep quietude and charm, the broad meadows slightly veiled with mist, the old-world towns of grey stone with their wonderful architecture, which were characteristic of Belgium in normal times. That country had in the past been swept by storms of civic passions and commotions and by hostile invasion. Such contrasts would be likely to produce in the inhabitants strange reflections, at times vehement and at times thoughtful, which might express themselves in the form of wonderful poetry of various kinds. Those who remembered how Mr. Maeterlinck had come home, so to speak, to many English people, as well as to those in every civilised country of Europe, would concede that one of the reasons of his appeal was his deep serenity, his extraordinary sincerity and his monumental simplicity—three qualities which were essential to a great writer. He had personally been struck by those three qualities when he had the honour of meeting Mr. Maeterlinck over twenty years ago and showing him over the Houses of Parliament, of which he (the speaker) was then a

member. The more one looked at his work the more one saw the inner meaning which was guiding and illuminating the whole of it. He had not only the gift of presenting facts clearly but he had also the gift of making those facts, as it were, germinate and grow within one's mind. His talents and genius had been familiarised to English people by the many stage representations of his works that had been produced in recent years, and those who were unable to follow him in his own language must feel deeply indebted to the very admirable translations by Mr. Alfred Sutro, which he thought approached as near the ideal as it was possible to attain in that most difficult of all the arts. Verhaeren and the other writers to whom the author had alluded were perhaps less generally known in this country, but they were very widely known and appreciated in France. During the previous autumn he had come across a very charming little anthology of French poets, edited by a young French poet of the present day, in which a large number of Flemish, Walloon, and Belgian poets were included, and in which full homage was paid to their manifold and exceptional merits. It must, he thought, be very satisfactory to people of Belgian nationality to reflect that beyond the confines of their own country their literature had established itself in a firm and recognised position. Some might imagine that it was not fitting at the present time, when everyone was beset by the stress and anxiety of the world-wide cataclysm which came home to them individually and nationally, to seek relief in literature and poetry from the thoughts and anxieties that oppressed them. That was not his own view. He thought it was a good thing to seek such relief not merely in a healthy spirit of cheery optimism—like Drake, who finished his game of bowls and then went out to defeat the Armada—but because it was good to steep one's soul in things of the spirit, and to keep the flame of the ideal bright within one, and the writers that had been mentioned in the paper that afternoon were all deeply impressed with the importance of the ideal. By that means one was able to endure and best fit oneself to meet whatever calls the present time of stress and trial and anguish might bring upon one.

The resolution of thanks was carried unanimously, and the CHAIRMAN then addressed the following words to the author:—

Monsieur,—Nous avons été heureux de vous recevoir ici et nous tenons à vous dire combien nous avons goûté l'admirable conférence que vous venez de nous donner. Cette conférence démontre, si je puis m'exprimer ainsi, qu'il y a un poète belge présent ici sur cette plateforme, car il y a l'accent de la poésie dans ce que nous avons eu l'honneur d'entendre aujourd'hui. Il est à espérer qu'avant longtemps votre belle patrie sera libérée pour toujours des hordes barbares qui la polluent et l'écrasent en ce moment. Je désire moi-même exprimer l'espoir que lorsque les termes de paix seront enfin signés, les œuvres d'art se trouvant actuellement dans les musées de l'Allemagne et qui proviennent de la Belgique, de la France et de la Pologne, devront être restituées, en dehors de l'indemnité large qui devra vous être allouée en réparation de l'œuvre de destruction brutale organisée dans votre pays et au cours de laquelle on a livré aux flammes des œuvres d'art qui devraient à tout jamais être sacrées pour tout peuple qui s'appelle civilisé.

The meeting then terminated.

COTTON MACHINERY WANTED IN ARGENTINA.

The Province of Tucuman is practically a one-crop region, the cultivation of sugar-cane having outstripped any other agricultural industry. The land is, however, suitable for other things. Some tobacco has been grown there, and last year linseed was successfully cultivated, a recent sale in Rosario of 600 tons of linseed from Tucuman demonstrating this capability of the soil.

Much of the northern region of Argentina has been subject to sporadic efforts to grow cotton. That it is suitable for cotton is evidenced by the tradition that the name "Tucuman" signifies, in the language of the indigenous people, "cotton," and the museums at Tucuman and elsewhere have samples of cloth by the natives which was woven from cotton grown there before the Spanish occupation. The cotton plant is seen in several isolated fields, and serious studies have been made by agronomists to encourage its cultivation, because of the large consumption of cotton cloth in Argentina.

The present Government of the Province of Tucuman, supported by the National Government's Department of Agriculture, is desirous of introducing the cotton industry. To that end it invited the attention of a group of cotton-men to study the possibilities of the province. These gentlemen are promised a concession of 5,000 hectares (12,355 acres) of land from the province at a moderate price for the cultivation of cotton. The concessionaires are to receive sufficient irrigation from the public irrigation works already established or projected. On their side they agree to bring from Spain 1,500 workmen, who are to form the nucleus of a colony in these cotton fields; they are to erect a factory on the land, which will be equipped with the most modern machinery for utilising the agricultural product, and among the workmen are to be many who have been skilled in weaving cotton cloth by such modern machinery.

According to a recent report by the United States Commercial Attaché at Buenos Aires, the project is assuming practical shape, and the hope is warranted that within a short time the conces-

sionaires will be in the market for the purchase of the equipment for these modern cotton-mills. The Commercial Attaché, at the invitation of the Governor of the Province of Tucuman, was permitted to study the proposition at first hand, and was given the opportunity to visit not only the city of Tucuman but the adjacent region, which, in all probability, will be selected for this new industry.

ENGINEERING NOTES.

Electric Traction on Mountain Railways.—The first actual tests on the Chicago, Milwaukee and St. Paul Railway's newly electrified mountain divisions in Montana were made on December 8th by officials and directors of the system, accompanied by engineers of the General Electric Company. The completed sections of the electrified district were traversed in three special cars drawn by one of the new 260-ton 3,000-volt electric locomotives. Passenger-train tests were made at speeds up to 70 miles per hour, after which the same locomotives were used in tonnage tests of goods trains, pulling 2,500 tons at a uniform speed of 16 miles per hour. At the conclusion of the tests the president and other officials who witnessed them expressed gratification at their complete success. The regenerative braking device included in the equipment of the 3,000-volt locomotives proved under the actual tests to be entirely successful. It was seen that the use of the air-brakes had been practically done away with except for station stops and emergency uses, and that an enormous saving could be expected in the lessening of wear and tear on track and equipment. The constant grinding of brake shoes on wheels is nearly eliminated. It is expected that the all-steel transcontinental trains of the railway will soon be operated electrically over the Continental Divide.

Electric Lifts.—In a paper read before the Association of Supervising Electricians, Mr. H. Marryat discussed the construction and management of electric lifts. Dividing lifts into two broad classes, sheave-driven and drum-driven, with the gear placed at either the top or the bottom, he said that all work on the see-saw principle. Not only is the car and its attendant, if any, fully counterweighted, but also a proportion, usually 40 per cent., of the maximum load. In these conditions the lift descending empty takes almost as much power as when ascending fully loaded, and exactly the same power as when ascending with 80 per cent. of its full load. On the other hand, with an average load of 80 per cent. of full load, it takes practically no power either ascending or descending. This system of counterbalancing part of the load accounts for the extraordinary efficiency of electric lifts. Compared with hydraulic lifts, their first cost is much the same, though a completely automatic lift may cost a little more than an ordinary hydraulic lift; but the running costs are always less, and in the author's experience modern examples cost for electric current about one-tenth of the water bill for similar hydraulic examples. The hydraulic lift uses the same amount of water whether the car be quite empty or fully loaded. The energy required for starting and accelerating a carefully balanced electric lift exceeds that of the actual running, and therefore a skilled attendant will effect great economy over an unskilled one, who will sometimes make two or three shots before attaining floor level. In this respect a push-button lift gives maximum economy, because it makes only one start for each journey, and automatically finds its own floor level. In regard to maintenance costs, the balance is again in favour of electric lifts. The adjustment of counterweights is an important matter. The maker, not knowing what the average load is going to be, has only the maximum load to guide him, and he usually assumes an average load of 40 per cent., and balances accordingly. But this estimate may prove quite wrong. Actual economies of 50 per cent. and upwards have been realised by attention to adjusting the correct counterweighting of lifts to the average load.

Gas from Wood.—It may be mentioned that this material is in more or less constant use in many of the smaller Australian gasworks. Only certain classes of timber are suitable for the purpose, the best being those of the box and red-gum varieties, which are intermixed with coal to the extent of about 25 per cent. By introducing the wood it is claimed that the resulting product offers many advantages over ordinary neat coal gas, chiefly owing to the fact that napthalene troubles are almost eliminated, while there is some considerable reduction in the amount of scurf deposited on the retort walls. In Australia it is found that the average yield of gas amounts to about 12,000 cubic feet per ton of wood carbonised; but the great drawback to the method of working is the charcoal which remains behind after the completion of the distillation. It is usual to separate the charcoal from the coke and to make use of it for heating the retort furnaces. As employed for power purposes, wood gas is invariably manufactured from waste material such as sawdust and shavings, or even leaves, and, except for detarring and washing, is consumed in the crude form and unmixed with any other gas. Suction plants designed for using wood waste are capable of working with material of any description between dust and lumps six inches in diameter. In general, in addition to the generator, it is necessary to install a condenser, washer and tar-extractor, so that all the connecting-pipes to the engine may be kept perfectly clear. The moistness of the wood has an important effect on results, and in the event of the water content being greater than 60 per cent. preliminary drying should be resorted to, otherwise difficulties will be encountered with the fire. Wood gas as obtained by distillation in gasworks has a calorific value of about 400 B.Th.U. per cubic foot, whereas that generated by the suction plant is

approximately 160 B.Th.U. The latter figure it will be noticed is, if anything, somewhat higher than the corresponding value of the gas obtained with anthracite producers. A successful method of using wood waste is that employed in the Brooks dual scheme. The wood is primarily carbonised in retorts in the ordinary way, when a gas equivalent to about 13,000 cubic feet per ton and having a calorific value of from 375 to 390 B.Th.U. is obtained. The resultant charcoal, which amounts to one-fifth of the original weight of the wood, is then transferred to suction producers and the mixed gas is employed for power purposes. The above particulars are from the *Times* Engineering Supplement.

The Evolution of the War Aeroplane.—A leading article in the *Engineering Record* of New York on the above subject concludes as follows: "Powerful machine guns are now regularly mounted on war planes, together with suitable devices for dropping incendiary and high-explosive bombs; but the time seems now at hand when still further evolution in powers of offence and defence is at hand. The Russians are reported to have developed some giant flying machines with double fusilage and engines of much greater power than hitherto tried. The French are known to have similar equipment under way, and even in this country experiments along the same line have been actively carried out. If those prove as successful as there is reason to expect, the next year of war will see armoured aeroplanes capable of flying hundreds of miles at great speed while carrying half a ton or more of explosives. Even now some of the largest French planes are equipped with one-pounder rapid-firing guns, and these probably will be replaced with light cannon of still larger calibre ere long. Thus armed and armoured the heavier-than-air machine becomes formidable for offence against raiding air crafts of various sorts. England is also reputed to be building air craft of great power in large numbers. In view of all this, it seems reasonably certain that by the end of the war the aeroplane will be in a position to take its place as a rather reliable means of emergency transportation, perhaps even as an aerial vehicle capable of performing regular service at high speed. The change which the year has produced is of a very startling character, and another year will bring still further surprises. It is certainly the duty of engineers and aviators in our country to see to it that we are not behind in the race for command of the air."

The Mixed Australian Railway Gauge.—Recently, at Tocumwal, New South Wales, a successful demonstration of the third-rail system, together with the Brennan patent switch (of torpedo and mono-rail fame) and the Wilkin's common-rail switch, was carried out in the presence of a representative gathering. Included amongst those present were the Governors of four States and the Railway Commissioners and Engineers of the Commonwealth and the States. The object of the display was to illustrate the ease with which the break of gauge between the Victorian and New South Wales systems 5 ft. 3 in. and 4 ft. 8½ in. respectively, can be overcome, and, judging by the smoothness which marked the trials, the difficulty has been solved. The experiments were carried out on a specially laid track outside the local station. The points and switches were designed by Mr. Wilkin, Interlocking Engineer, while the line was laid under the supervision of Mr. Henry Deane, M.Inst.C.E., late Engineer in Chief of the Commonwealth Railways. The object of the Government was to test the Brennan patent switches under service conditions, and for the purpose a series of switches, points, and other apparatus was laid down on a plan that would be met with under working conditions where a break of gauge was to be overcome.

Mr. Wilkin also installed a switch of his own design for a change of common rail which enables engines of both gauges to be turned on the one turntable. The first test was the passing of a New South Wales engine and train over a mixed gauge cross-over, which connects together two parallel lines of different gauges. Then a Victorian train did likewise. A feature of this cross-over was that it was worked by one lever only. Moving farther up the line, the visitors were then shown a Victorian train running on a three-line track turning into a Victorian gauge siding. Tests were then made with the Brennan patent switches, which formed a junction, and which were completely signalled and interlocked. Trains of both States flew over the switches at close on forty miles an hour. Tests were then made with the Wilkin's change of common-rail device, by which means a New South Wales train was brought the same distance from a platform as the Victorian train. The experiments were concluded with the trial of the Wilkin's turntable, on which engines of both gauges can be turned. The New South Wales engineers were highly satisfied with the practicability of the inventions. The representatives of other States will report to their Governments. The upshot and moral of the whole is that our politicians—for it was their fault altering the gauge, not the engineers, who protested—will thereby probably incur several millions of useless expenditure, whatever the means adopted to enable uniformity to be attained.

GENERAL NOTES.

Potassium in Alsace.—In an article in the *Revue Générale des Sciences*, M. Henri Blin describes the deposits of potassium salts in Alsace. They were discovered in 1904, and cover an area of some 50,000 acres. They are bounded on the east by Mulhouse, on the north by Radersheim, on the south by Keiningen, and on the west by Cernay, and are worked at Wittelsheim, to the north of

Mulhouse. Should Alsace again become French, they will form an inexhaustible supply of chemical fertilisers for French agriculture. It is estimated that the beds contain some 3,000,000 tons of pure potash, which at present rates of consumption would supply the world demand for potash for nearly five centuries. The most important constituent of the Alsatian deposits is sylvinite—a mineral in which the chloride of potassium predominates—which can be used as a fertiliser directly after pulverisation.

PORTLAND CEMENT.—Owing to the shortage of German and Belgian supplies of Portland cement, a good deal of attention is being given to the manufacture of this material abroad, in places where limestone, shale, or clay and coal can be obtained of suitable quality and in sufficient quantities to make the manufacture likely to be successful and remunerative. The Queensland Cement and Lime Company has now arranged to establish a works at Darra, near Brisbane. The plant is designed to produce about 40,000 tons of cement per annum. The complete contract for the supply and erection of the plant, which will be of entirely British manufacture, has been placed with Messrs. Noyes Brothers, Sydney. Grinding mills of the combination ball and tube mill type, and a kiln 140 ft. long and 8 ft. in diameter, will be erected; and these, together with all the subsidiary plant, will be electrically driven, direct-coupled wherever possible. The motors are for 3-phase, 50 cycles, 440 volts, and will be supplied with power from generating plant in the works, which will be direct-coupled to vertical high-speed engines. The general lay-out of the plant has been made with the expectation that the works will soon be duplicated and even further increased.

COFFEE CROP OF SALVADOR.—According to a report by the United States Vice-Consul at San Salvador, preparations are now being made to harvest the 1915–16 coffee crop of Salvador, which it is believed will reach a total of 75,000,000 lb.; 60,000,000 lb. will probably be exported. This is considered to be a very good crop and compares favourably with the crop of the preceding year, which was 77,007,000 lb., produced in the following Departments:—Santa Ana, 12,888,000 lb.; Ahuachapán, 8,137,400 lb.; Sonsonate, 5,573,400 lb.; La Libertad, 14,174,400 lb.; San Salvador, 2,480,100 lb.; Chalatenango, 88,700 lb.; Cuscatlan, 489,000 lb.; La Paz, 8,788,600 lb.; San Vicente, 753,000 lb.; Cabañas, 286,300 lb.; San Miguel, 4,861,700 lb.; Usulutan, 18,071,000 lb.; Morazan, 404,700 lb.; and La Union, 11,000 lb. There are approximately 211,000 acres planted in coffee trees in Salvador.

SPANISH HORSE-BEAN CROP.—One of the crops that is largely raised in Andalusia, and is appearing more frequently among the exports, is the horse-bean, or "haba" (*Faba vulgaris*). According to a report by the U.S. Consul at Seville, statistics have been issued recently by the Director-General of Agriculture, showing that the production of "habas" in Spain amounts to 146,975 metric tons (metric ton = 2,204·6 lb.). The area devoted to the cultivation of this legume is 206,910 acres, viz., 87,586 acres in irrigated districts, producing 50,190 metric tons, and 119,324 acres cultivated by dry-farming methods, producing 96,785 metric tons. The districts of Spain in which the crops are the largest are Eastern Andalusia (32,020 tons), Western Andalusia (27,830 tons), and Navarra and the Basque Provinces (12,860 tons).

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

MARCH 8.—CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Optical Appliances in Warfare." DR. R. T. GLAZEBROOK, C.B., F.R.S., Director of the National Physical Laboratory, will preside.

MARCH 15.—EDWARD PERCY STEBBING, F.L.S., F.R.G.S., Head of the Department of Forestry, University of Edinburgh, "Forestry and the War."

MARCH 22.—REV. P. H. DITCHFIELD, M.A., "The England of Shakespeare."

MARCH 29.—R. W. SETON-WATSON, D.Litt., "Pan-German Aspirations in the Near East."

APRIL 5.—ARTHUR S. JENNINGS, "Painting by Dipping, Spraying, and other Mechanical Means."

MAY 3.—PROFESSOR W. B. BOTTOMLEY, M.A., F.C.S., F.L.S., "Bacterised Peat."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

APRIL 6.—PROFESSOR WYNDHAM R. DUNSTAN, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India." THE RIGHT HON. LORD ISLINGTON, G.C.M.G., will preside.

APRIL 27.—JAMES MACKENNA, M.A., I.C.S. (Deputy Commissioner, Myaungmya, Burma, and designated Agricultural Adviser to the Government of India), "Scientific Agriculture in India."

MAY 18.—SARDAR DALJIT SINGH, C.S.I., "The Sikhs."

Colonial Section.

Tuesday afternoons, at 4.30 p.m. :—

March 28.—Percy Hurd, "Next Steps in Empire Partnership."

April 11.—Sir Daniel Morris, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland."

Dates to be hereafter announced :—

W. A. Craigie, M.A., LL.D., Joint Editor of the Oxford English Dictionary, "The Lexicography of the Arts and Sciences."

Victor Horta, Directeur de l'Académie Royale des Beaux-Arts de la Ville de Bruxelles, "Belgian Architecture."

Professor T. G. Masaryk, "The Slavonic Peoples."

G. P. Baker, "Hindu Hand-painted Calicoes of the Seventeenth and Eighteenth Centuries, and their Influence on the Tinctorial Arts of Europe."

Cantor Lectures.

Monday afternoons, at 4.30 p.m. :—

J. Erskine-Murray, D.Sc., F.R.S.E., M.I.E.E., "Vibrations, Waves, and Resonance." Four Lectures.

May 1, 8, 15, 22.

Fothergill Lectures.

Monday afternoons, at 4.30 p.m. :—

Edward A. Reeves, F.R.A.S., Map Curator, Royal Geographical Society, "Surveying." Three Lectures.

March 27, April 3, 10.

MEETINGS FOR THE ENSUING WEEK.

Monday, March 6...Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Rev. H. J. R. Marston, "The Psychology of St. Paul."

Economics and Political Science, London School of, Clare-market, W.C., 5 p.m. Hon. W. P. Reeves, "The Balkan States." (Lecture V.)

Engineers, Society of, Caxton Hall, Westminster, S.W., 5.30 p.m. Mr. R. Brown, "Sewage and its Precipitation: Facts and Fallacies from Laboratory and Practical Tests."

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m.

Surveyors' Institution, 12, Great George-street, S.W., 5 p.m. Mr. G. Turville Brown, "Management of Estates in Mineral Districts and Mineral Valuations."

Geographical Society Burlington-gardens, W., 8.30 p.m. Mr. C. M. Woodford, "Some Little-known Polynesian Settlements near the Solomon Islands."

Medicine, Royal Society of, 1, Wimpole-street, W., 5.30 p.m. Debate on "War Injuries of the Jaws and Face."

Tuesday, March 7...Royal Institution, Albemarle-street, W., 3 p.m. Dr. E. J. Russell, "The Plant and the Soil." (Lecture II.)

Alpine Club, 23, Savile-row, W., 8.30 p.m. Rev. W. Weston, "Annals of Fuji San."

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Mr. H. Cox, "Industrial Development."

Zoological Society, Regent's Park, N.W., 5 p.m. Cinematographic Exhibition of African Animals by Mr. H. K. Eustace.

Röntgen Society, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8.15 p.m. 1. Discussion on "The Injurious Effects Produced by X-Rays." 2. Mr. A. C. Gunstone, "The Use of Inverse Current."

Wednesday, March 8...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. C. R. Darling, "Optical Appliances in Warfare."

Automobile Engineers, Institution of, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Mr. J. L. Hodgson, "The Fan Dynamometer."

Biblical Archæology, Society of, 37, Great Russell-street, W.C., 4.30 p.m. Mr. S. Langdon, "New Fragments of the Babylonian Book of Wisdom."

Geological Society, Burlington House, W., 8 p.m.

Electrical Engineers, Institution of (Yorkshire Section), Philosophical Hall, Leeds, 7 p.m. Mr. H. Joseph, "Hire and Maintenance of Continuous Current Motors."

University of London, King's College, Strand, W.C., 5.15 p.m. Mr. R. Dmowski, "Poland and Germany."

Medicine, Royal Society of, 1, Wimpole-street, W., 5 p.m. Dr. L. S. Dudgeon, "Experiences in the Gallipoli Peninsula and Eastern Mediterranean."

Thursday, March 9...London Society, at the Royal Society of Arts, John-street, Adelphi, W.C., 5.30 p.m. Annual Meeting.

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Sanitary Institute, 90, Buckingham Palace-road, S.W., 4.30 p.m. Dr. J. W. Mason, "Food Inspection, Standards of Purity for Food Supply in War-Time, and the Utilisation of Condemned Stores."

Royal Institution, Albemarle-street, W., 3 p.m. Professor L. W. King, "Recent Excavations in Mesopotamia." (Lecture II.)

Optical Society, at the Chemical Society, Burlington House, W., 8 p.m. 1. Mr. T. F. Connolly, "A Simple Focometer for the Determination of Short Focal Lengths both Negative and Positive." 2. Mr. F. E. Smith, "The Manufacture and Testing of Prismatic and other Compasses."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Mr. E. V. Pannell, "Continuous-Current Railway Motors."

Friday, March 10...Royal Institution, Albemarle-street, W., 5.30 p.m. Sir Napier Shaw, "Illusions of the Upper Air."

Astronomical Society, Burlington House, 5 p.m.

University of London, Bedford College, York Gate, N.W., 5 p.m. Miss H. D. Oakeley, "The International Crisis—the Idea of a General Will."

Economics and Political Science, London School of, Clare-market, W.C., 5 p.m. Mr. C. Turnor, "The Land and the Empire."

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

Medicine, Royal Society of, 1, Wimpole-street, W., 5 p.m. Dr. M. Weinberg, "Bacteriological and Experimental Researches on Gas Gangrene."

Saturday, March 11...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Radiations from Atoms and Electrons." (Lecture I.)

Journal of the Royal Society of Arts.

No. 3,303. VOL. LXIV.

FRIDAY, MARCH 10, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, MARCH 15th, 4.30 p.m. (Ordinary Meeting.) EDWARD PERCY STEBBING, F.L.S., F.R.G.S., Head of the Department of Forestry, University of Edinburgh, "Forestry and the War."

Further particulars of the Society's meetings will be found at the end of this number.

PETER LE NEVE FOSTER PRIZE.

The prize of £10 and a Silver Medal, offered under the Peter Le Neve Foster Trust, for an essay on "Zinc, its Production and Industrial Applications," has been awarded by the Council to Mr. J. C. Moulden, A.R.S.M., M.Inst.M.M., of Seaton Carew, Co. Durham. Honourable mention has also been awarded to Mr. Ernest Alfred Smith, A.R.S.M., M.Inst.M.M., Deputy Assay Master of the Sheffield Assay Office, for his essay.

The adjudicators, on whose recommendation the award was made, reported that the two essays above mentioned were distinctly superior to the others, several of which, nevertheless, were of interest and value. An essay by Mr. Ramji Das Vaishya, of Gwalior, Central India, contained a good deal of information with regard to the production and utilisation of the metal in the East Indies.

The prize essay will be read in abstract at one of the meetings of the Society after Easter.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal of the Royal Society of Arts for 1916 early in May next, and they therefore invite members of the Society to forward to the Secretary on or before Saturday, March 25th, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce," and has been awarded in previous years as follows;—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S., "for his great services to Arts, Manufactures, and Commerce, in the creation of the penny postage, and for his other reforms in the postal system of this country, the benefits of which have, however, not been confined to this country, but have extended over the civilised world."

In 1865, to his Imperial Majesty, Napoleon III., "for distinguished merit in promoting, in many ways, by his personal exertions, the international progress of Arts, Manufactures, and Commerce, the proofs of which are afforded by his judicious patronage of Art, his enlightened commercial policy, and especially by the abolition of passports in favour of British subjects."

In 1866, to Michael Faraday, D.C.L., F.R.S., "for discoveries in electricity, magnetism, and chemistry, which, in their relation to the industries of the world, have so largely promoted Arts, Manufactures, and Commerce."

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S., "in recognition of their joint labours in establishing the first electric telegraph."

In 1868, to Mr. (afterwards Sir) Joseph Whitworth, LL.D., F.R.S., "for the invention and manufacture of instruments of measurement and uniform standards, by which the production of machinery has been brought to a state of perfection hitherto unapproached, to the great advancement of Arts, Manufactures, and Commerce."

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, etc., "for his numerous valuable researches and writings, which have contributed most importantly to the development of food economy and agriculture, to the advancement of chemical science, and to the benefits derived from that science by Arts, Manufactures, and Commerce."

In 1870, to Vicomte Ferdinand de Lesseps, Member of the Institute of France, Hon. G.C.S.I.,

"for services rendered to Arts, Manufactures, and Commerce by the realisation of the Suez Canal."

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B., "for his important services in promoting Arts, Manufactures, and Commerce, especially in aiding the establishment and development of International Exhibitions, the Department of Science and Art, and the South Kensington Museum."

In 1872, to Mr. (afterwards Sir) Henry Bessemer, F.R.S., "for the eminent services rendered by him to Arts, Manufactures, and Commerce in developing the manufacture of steel."

In 1873, to Michel Eugène Chevreul, For. Memb. R.S., Member of the Institute of France, "for his chemical researches, especially in reference to saponification, dyeing, agriculture, and natural history, which for more than half a century have exercised a wide influence on the industrial arts of the world."

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S., "for his researches in connection with the laws of heat, and the practical applications of them to furnaces used in the Arts; and for his improvements in the manufacture of iron; and generally for the services rendered by him in connection with economisation of fuel in its various applications to Manufactures and the Arts."

In 1875, to Michel Chevalier, "the distinguished French statesman, who, by his writings and persistent exertions, extending over many years, has rendered essential services in promoting Arts, Manufactures, and Commerce."

In 1876, to Sir George B. Airy, K.C.B., F.R.S., Astronomer Royal, "for eminent services rendered to Commerce by his researches in nautical astronomy and in magnetism, and by his improvements in the application of the mariner's compass to the navigation of iron ships."

In 1877, to Jean Baptiste Dumas, For. Memb. R.S., Member of the Institute of France, "the distinguished chemist, whose researches have exercised a very material influence on the advancement of the Industrial Arts."

In 1878, to Sir Wm. G. Armstrong (afterwards Lord Armstrong), C.B., D.C.L., F.R.S., "because of his distinction as an engineer and as a scientific man, and because by the development of the transmission of power—hydraulically—due to his constant efforts, extending over many years, the manufactures of this country have been greatly aided, and mechanical power beneficially substituted for most laborious and injurious manual labour."

In 1879, to Sir William Thomson (afterwards Lord Kelvin), O.M., LL.D., D.C.L., F.R.S., "on account of the signal service rendered to Arts, Manufactures, and Commerce by his electrical researches, especially with reference to the transmission of telegraphic messages over ocean cables."

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S., "for having established, after most laborious research, the true relation between heat, electricity, and mechanical work, thus affording to the engineer a sure guide in the application of science to industrial pursuits."

In 1881, to August Wilhelm Hofmann, M.D., LL.D., F.R.S., Professor of Chemistry in the University of Berlin, "for eminent services rendered to the Industrial Arts by his investigations in organic chemistry, and for his successful labour in promoting the cultivation of chemical education and research in England."

In 1882, to Louis Pasteur, Member of the Institute of France, For. Memb. R.S., "for his researches in connection with fermentation, the preservation of wines, and the propagation of zymotic diseases in silkworms and domestic animals, whereby the arts of wine-making, silk production, and agriculture have been greatly benefited."

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S., "for the eminent services which, as a botanist and scientific traveller, and as Director of the National Botanical Department, he has rendered to the Arts, Manufactures, and Commerce by promoting an accurate knowledge of the floras and economic vegetable products of our several colonies and dependencies of the Empire."

In 1884, to Captain James Buchanan Eads, "the distinguished American engineer, whose works have been of such great service in improving the water communications of North America, and have thereby rendered valuable aid to the commerce of the world."

In 1885, to Mr. (afterwards Sir) Henry Doulton, "in recognition of the impulse given by him to the production of artistic pottery in this country."

In 1886, to Samuel Cunliffe Lister (afterwards Lord Masham), "for the services he has rendered to the textile industries, especially by the substitution of mechanical wool combing for hand combing, and by the introduction and development of a new industry—the utilisation of waste silk."

In 1887, to HER MAJESTY QUEEN VICTORIA, "in commemoration of the progress of Arts, Manufactures, and Commerce throughout the Empire during the fifty years of her reign."

In 1888, to Professor Hermann Louis Helmholtz, For. Memb. R.S., "in recognition of the value of his researches in various branches of science, and of their practical results upon music, painting, and the useful arts."

In 1889, to John Percy, LL.D., F.R.S., "for his achievements in promoting the Arts, Manufactures, and Commerce through the world-wide influence which his researches and writings have had upon the progress of the science and practice of metallurgy."

In 1890, to Dr. (afterwards Sir) William Henry Perkin, F.R.S., "for his discovery of the method of obtaining colouring matter from coal tar—a discovery which led to the establishment of a new and important industry, and to the utilisation of large quantities of a previously worthless material."

In 1891, to Sir Frederick Abel, Bart., G.C.V.O., K.C.B., D.C.L., D.Sc., F.R.S., "in recognition of the manner in which he has promoted several important classes of the Arts and Manufactures, by the application of Chemical Science, and especially by his researches in the manufacture of iron and of steel; and also in acknowledgment of the great services he has rendered to the State in the provision of improved war material, and as Chemist to the War Department."

In 1892, to Thomas Alva Edison, "in recognition of the merits of his numerous and valuable inventions, especially his improvements in telegraphy, in telephony, and in electric lighting, and for his discovery of a means of reproducing vocal sounds by the phonograph."

In 1893, to Sir John Bennet Lawes, Bart., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S., "for their joint services to scientific agriculture, and notably for the researches which, throughout a period of fifty years, have been carried on by them at the Experimental Farm, Rothamsted."

In 1894, to Sir Joseph (afterwards Lord) Lister, F.R.S., "for the discovery and establishment of the antiseptic method of treating wounds and injuries, by which not only has the art of surgery been greatly promoted, and human life saved in all parts of the world, but extensive industries have been created for the supply of materials required for carrying the treatment into effect."

In 1895, to Sir Isaac Lowthian Bell, Bart., F.R.S., "in recognition of the services he has rendered to Arts, Manufactures, and Commerce by his metallurgical researches and the resulting development of the iron and steel industries."

In 1896, to Professor David Edward Hughes, F.R.S., "in recognition of the services he has rendered to Arts, Manufactures, and Commerce by his numerous inventions in electricity and magnetism, especially the printing telegraph and the microphone."

In 1897, to George James Symons, F.R.S., "for the services he has rendered to the United Kingdom by affording to engineers engaged in the water-supply and the sewerage of towns a trustworthy basis for their work, by establishing and carrying on during nearly forty years' systematic observations (now at over 3,000 stations) of the rainfall of the British Isles, and by recording, tabulating, and graphically indicating the results of these observations in the annual volumes published by himself."

In 1898, to Professor Robert Wilhelm Bunsen, M.D., For. Memb. R.S., "in recognition of his numerous and most valuable applications of Chemistry and Physics to the Arts and to Manufactures."

In 1899, to Sir William Crookes, O.M., F.R.S., "for his extensive and laborious researches in chemistry and in physics—researches which have, in many instances, developed into useful practical applications in the Arts and Manufactures."

In 1900, to Henry Wilde, F.R.S., "for the discovery and practical demonstration of the indefinite increase of the magnetic and electric forces from quantities indefinitely small—a discovery now used in all dynamo machines—and for its application to the production of the electric searchlight, and to the electro-deposition of metals from their solutions."

In 1901, to His Majesty King Edward VII., "in recognition of the aid rendered by His Majesty to Arts, Manufactures, and Commerce during thirty-eight years' Presidency of the Society of Arts, by undertaking the direction of important exhibitions in this country, and the executive control of British representation at International Exhibitions abroad, and also by many other services to the cause of British Industry."

In 1902, to Professor Alexander Graham Bell, "for his invention of the telephone."

In 1903, to Sir Charles Augustus Hartley, K.C.M.G., "in recognition of his services, extending over forty-four years, as Engineer to the International Commission of the Danube, which have resulted in the opening up of the navigation of that river to ships of all nations, and of his similar services, extending over twenty years, as British Commissioner on the International Technical Commission of the Suez Canal."

In 1904, to Walter Crane, "in recognition of the services he has rendered to Art and Industry by awakening popular interest in Decorative Art and Craftsmanship, and by promoting the recognition of English Art in the form most material to the commercial prosperity of the country."

In 1905, to Lord Rayleigh, O.M., D.C.L., Sc.D., F.R.S., "in recognition of the influence which his researches, directed to the increase of scientific knowledge, have had upon industrial progress, by facilitating, amongst other scientific applications, the provision of accurate electrical standards, the production of improved lenses, and the development of apparatus for sound signalling at sea."

In 1906, to Sir Joseph Wilson Swan, M.A., D.Sc., F.R.S., "for the important part he took in the invention of the incandescent electric lamp, and for his invention of the carbon process of photographic printing."

In 1907, to the Earl of Cromer, O.M., G.C.B., G.C.M.G., K.C.S.I., C.I.E., "in recognition of his pre-eminent public services in Egypt, where he has imparted security to the relations of this country with the East, has established justice, restored order and prosperity, and, by the initiation of great works, has opened up new fields for enterprise."

In 1908, to Sir James Dewar, M.A., D.Sc., LL.D., F.R.S., "for his investigations into the liquefaction of gases and the properties of matter at low temperatures—investigations which have resulted in the production of the lowest temperatures yet reached, the use of vacuum vessels for thermal isolation, and the application of cooled charcoal to the separation of gaseous mixtures and to the production of high vacua."

In 1909, to Sir Andrew Noble, K.C.B., D.Sc., D.C.L., F.R.S., "in recognition of his long-continued and valuable researches into the nature and action of explosives, which have resulted in the great development and improvement of modern ordnance."

In 1910, to Madame Curie, "for the discovery of radium."

In 1911, to the Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., D.Sc., F.R.S., "for his experimental researches into the laws governing the efficient action of steam in engines of the turbine type, and for his invention of the re-action type of steam turbine, and its practical application to the generation of electricity and other purposes."

In 1912, to the Right Hon. Lord Strathcona and Mount Royal, G.C.M.G., G.C.V.O., LL.D., D.C.L., F.R.S., "for his services in improving the railway communications, developing the resources, and promoting the commerce and industry of Canada and other parts of the British Empire."

In 1913, to His Majesty King George V., "in respectful recognition of His Majesty's untiring efforts to make himself personally acquainted with the social and economical conditions of the various parts of his Dominions, and to promote the progress of the Arts, Manufactures, and Commerce in the United Kingdom and throughout the British Empire."

In 1914, to Chevalier Guglielmo Marconi, LL.D., D.Sc., "for his services in the development and practical application of wireless telegraphy."

In 1915, to Professor Sir Joseph John Thomson, O.M., D.Sc., LL.D., F.R.S., "for his researches in physics and chemistry, and their application to the advancement of Arts, Manufactures, and Commerce."

PROCEEDINGS OF THE SOCIETY.

THIRTEENTH ORDINARY MEETING.

Wednesday, March 8th, 1916; Richard T. Glazebrook, C.B., M.A., D.Sc., F.R.S., Director of the National Physical Laboratory, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Middleton, Austin R., Baltimore, Maryland, U.S.A.

Patel, J. M. Framjee, J.P., Cumballa Hill, Bombay, India.

Starr, William J., LL.B., Eau Claire, Wisconsin, U.S.A.

The following candidates were balloted for and duly elected Fellows of the Society:—

Jeejeebhoy, Merwanjee D. M., 78, Apollo-street, Fort, Bombay, India.

Mukerji, B. K., Lashkar, Gwalior, India.

Oliphant, Professor Samuel Grant, A.M., Ph.D., Grove City College, Grove City, Pennsylvania, U.S.A.

The paper read was—

OPTICAL APPLIANCES IN WARFARE.

By Charles R. Darling, A.R.C.Sc.I., F.I.C.

In a lecture delivered to a military audience in 1865, John Ruskin made use of the following sentence: "There is no form of science which a soldier may not at some time or other find bearing on business of life and death." The truth of this utterance has been fully borne out in the present conflict, in which all the resources of science are being utilised for one or other end. It will not be out of place, therefore, to lay before the Society an account —necessarily incomplete in the compass of a single paper—of the application of one branch of science, that of Optics, to modern warfare.

In dealing with the optical appliances used in the field, which comprise a large number of separate items, it is not possible to give a detailed account of each, as a whole paper might be devoted to a single class of instruments, such as range-finders. In the present paper, therefore, it is intended to take a general survey of the whole subject, so as to convey an idea of the nature of the optical instruments used and the purposes they fulfil.

The following are the chief optical appliances used in warfare:—

1. Field-glasses and telescopes.
2. Searchlights.
3. Periscopes.
4. Range-finders.
5. Signalling lamps and heliographs.

In addition to the above, cameras, prismatic compasses, surveying instruments, etc., are used; but it is only proposed in the present paper to deal with appliances specially devoted to warfare, and embraced in the above five headings, which will be treated in turn.

Field-Glasses and Telescopes.

As an aid to vision, field-glasses or telescopes are essential in military operations, and a number of different patterns, varying according to circumstances, are in use. Binoculars on the principle of the Galilean telescope possess several drawbacks as compared with modern prismatic glasses, notably that the field of view is small and the magnification low, and also that cross-wires cannot be introduced, owing to the fact that no real image of the object is

produced. On the other hand, they give good illumination, and in a dull or dark atmosphere may be used to advantage. Patterns with magnifying powers of three, four and five respectively are in use, having fields of view ranging from about 3° to 4° 30′.

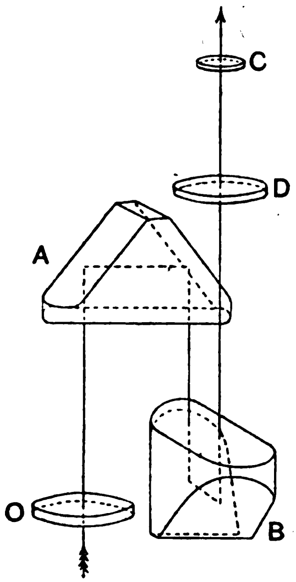

FIG. 1.

The prismatic binoculars introduced by the firm of Zeiss have the advantages: (1) That a long-focus object-glass may be used in a short body; (2) an increased field of view is obtained, with greater stereoscopic power, by placing the object-glasses further apart than the eyepieces; and (3) a real image of the object is formed, enabling cross-wires or graticules to be used. The path of the central ray through one side is shown in Fig. 1. The object-glass O, in the absence of prisms, would form an inverted image of the object; but in passing through the prism A the image is reversed from left to right, and in B, which is placed at right angles to A, the image is reversed vertically, an erect image thus being formed in the focal plane of the eyepiece, which is composed of two lenses, C and D, which magnify the image without inversion. In effect, this arrangement is equivalent to an ordinary telescope, of length equal to the path of the central ray; and as the magnifying power is equal to

$$\frac{\text{Focal length of object-glass}}{\text{Focal length of eyepiece,}}$$

it is evident that a great advantage is gained by lengthening the path of the ray and increasing the focal length of the eyepiece. Patterns are issued with magnifying powers of six and eight, and with fields of view ranging from 4° 30′ to about 8° 30′, figures which show a marked advantage over the Galilean type. In some of these graticules are fitted in the focal plane of the object-glass. These consist of a number of lines ruled on a glass plate, spaced out so as to represent minutes of deflection to right and left, as shown in Fig. 2, which assist in accurately determining the position of an object in the field of view. If rotated through a right angle, the graticules may be used similarly for elevated objects, the dimensions of which may thus be estimated.

A number of different kinds of telescopes, fitted with special devices, are used either for general observations, or as distinctive parts of instruments, such as directors or gun-sights, the magnifying power ranging from three to thirty-five. In some patterns the magnification may be varied over a large range—from five to twenty diameters—by a single movement, without disturbing the focus of the sighted object. This is accomplished, in the Ross pattern, by moving the erecting lens further away from the eyepiece, that is, nearer to the image formed by the object-glass. The size of the upright image, viewed by the eyepiece, is thereby increased, and the final image is correspondingly magnified. If the erecting lens alone were altered in position, the object would no longer be in focus; but by means of a mechanical device the eyepiece is made to move simultaneously by the amount necessary to retain the focus. The advantage of a variable power telescope is that the low power may be used as finder, whilst the high power can be

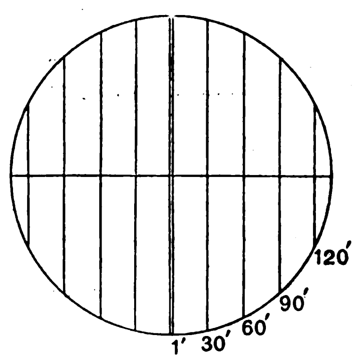

FIG. 2.

brought in for better definition without changing the focus. The initial adjustment is carried out by means of a movement independent of that which produces the change of power.

When telescopes are used as gun-sights, a pointer, or sighting-wire, is placed in the focal

plane of the object-glass, where the image of the target will be formed, and when the image is seen to coincide with the assigned mark the aim is correct. This method of sighting is preferable to the alignment of the target with a fore-sight and back-sight, as in this case the eye cannot be focussed for all three points at once, and a greater or less degree of uncertainty results; whereas with a telescopic sight both target and auxiliary mark are in focus at the same time. Telescopic sights have also been applied to rifles, a similar advantage being gained. When a telescopic sight is used at night it is necessary to illuminate the lines or pointer, and this is usually accomplished by means of a small electric lamp inserted in a suitable position in the telescope.

For observing the effect of artillery fire, the stereo-telescope, also due to the firm of Zeiss, is much used, as its stereoscopic power enables a much better judgment of distances to be formed than in the case of an ordinary telescope. This instrument is a binocular with hinged tubes, which may be moved to any desired angle between the vertical and horizontal, the stereoscopic power increasing as the distance between the object-glasses becomes greater. Rays from the object enter each tube by a window, in front of which is a prism which reflects the light on to the object-glass, and by means of two prisms at right angles the rays are brought into the eyepiece. This telescope may be used with the tubes at any angle, or an object may be sighted over a wall or parapet without exposing the observer. One pattern in common use has a magnifying power of ten diameters, with a field of view of 4°, and has one eyepiece fitted with a graticuled diaphragm, which may be used horizontally or vertically, for accurate observation of positions.

Searchlights.

The searchlight does not play a prominent part in land warfare under present conditions, as it would be too conspicuous an object, and when illumination is required star-shells are used. As a means of sighting air craft, for coast defence, and for naval purposes, however, the searchlight is indispensable. The source of light is an electric arc, fed by clockwork, which is placed at the focus of a concave mirror. This mirror forms the end of a tube out of which the reflected rays are projected, and which is mounted on a base so as to be capable of horizontal or vertical movement. As the focus of a mirror is a point, it is evident that only one point of the crater of the arc can occupy this position, and rays emanating from this point, after reflexion, will proceed in lines parallel to the axis of the mirror. From all other portions of the crater, however, the rays will be reflected from the mirror at an angle to the axis, the value of which, under working conditions, is 2° or 3°. Hence the beam as a whole is divergent, and lights up a much larger area than that of the mirror itself; whereas, if all the rays were parallel the illuminated area would only be equal to that of the mirror. At a distance of 2,000 yards the illuminated area, owing to this divergence, usually has a diameter of 100 yards, and enables objects comprised in this area to be clearly seen. The shape of the mirror or reflector is a matter of the greatest importance if a satisfactory beam is to be obtained. A spherical surface, owing to

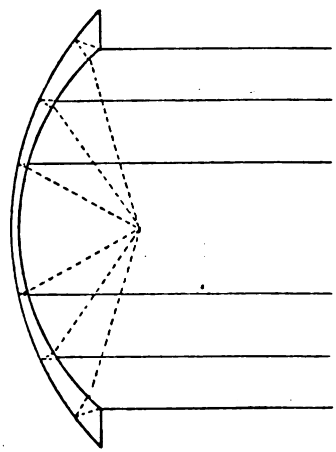

FIG. 3.

the aberration produced by the edges, is not suitable. In the reflector invented by Colonel Mangin, of the French Engineers (Fig. 3), this difficulty was overcome by the use of a glass mirror, silvered at the back, the front face possessing a greater curvature than the outer face, so that the reflector was thicker at the edges than at the centre. The rays, being more refracted at the edges, were thus made to escape in a direction parallel to the axis when emanating from the focus, thus correcting for aberration. These reflectors gave an excellent beam, but being made of glass were liable to breakage, either in transport or due to the heat of the arc, and have now been almost entirely superseded. For ordinary working paraboloid mirrors, made of metal, are now used, the reflecting surface being of silver or gold, or occasionally palladium or nickel. When it is desired to light up a large area at short range, the mirror used is parabolic

in vertical section and elliptical in horizontal section; the focus of the parabola coinciding with one of the foci of the ellipse. As all rays emanating from one focus of an ellipse pass after reflection through the other focus, the beam spreads out horizontally, but retains its normal dimensions vertically owing to the parabolic section. The amount of lateral dispersion produced in this manner may be as much as 45°, and hence a large area may be illuminated. An alternative method of producing a diverging beam is to place a number of positive cylindrical lenses in the path of the beam side by side, each of which brings the rays from a portion of the mirror to a focus on a line beyond the lens, from which the rays afterwards diverge. By using two rows of lenses, that nearest the mirror being fixed whilst the outer row is movable, any desired degree of dispersion may be secured. This form is generally used for naval purposes, and has the advantage of enabling one form of beam to be adapted to all conditions. The diameters of the reflectors used range from 120 cms. (nearly 4 ft.) to 35 cms. (14 in.); and the focal lengths from 65 cms. (25·5 in.) to 15 cms. (6 in.).

The carbons used for the arc vary in size, according to the current used, and are placed horizontally. The positive carbon, in which the crater is formed, faces the mirror, and is made of larger diameter than the negative, and is provided with a graphite core in order to keep the crater central. The smaller size of the negative carbon results in less obstruction of the light from the crater. The diameter of the crater ranges from 9 mm. in a 20-ampere lamp to 23 mm. in a lamp taking 150 amperes, the diameters of the positive and negative carbons being 18 mm. and 12 mm. respectively in the former case, and 38 mm. and 26·5 mm. in the latter.

There are many optical principles involved in the structure of a searchlight beam which cannot be entered into in detail in a paper of this description, and accordingly only conclusions will be given. Each point on the mirror reflects the image of the crater, and sends out a cone of light; the cones emanating from the central part having nearly circular bases, whilst those reflected from the edges have elliptical bases, as the projection of the crater on these portions is an ellipse. The resultant beam is a blending of these cones, and consists of an evenly-illuminated centre, round which the brightness diminishes to zero at the edges. The cones from the central portion of the mirror have dark centres, owing to the negative carbon shutting off some of the light of the crater, and the reflected light from the edges also possesses a dark portion, though not central, due to the same cause. All these points may be noted on looking at the projection of a searchlight beam on the clouds.

The following laws hold good for the beam:—

1. The diameter of the illuminated area is proportional to the diameter of the crater.

2. The diameter of the illuminated area is independent of the area of the mirror.

3. The diameter of the illuminated area is inversely proportional to the focal length of the mirror.

4. The diameter of the illuminated area is directly proportional to the distance from the projector.

5. The intensity of illumination is independent of the size of the crater, and of the focal length of the mirror.

6. The intensity of illumination is directly proportional to the area of the mirror, and inversely proportional to the square of the distance from the projector.

From these laws it may be gathered that the greater the area to be illuminated, the larger must be the diameters of the mirror and crater.

In order to secure a steady light, the voltage at the lamp terminals must be kept constant. A 90-ampere arc, for example, requires 56 volts, and the supply voltage must be reduced to and kept at this figure by the use of a series resistance. The carbons should be homogeneous, so as to secure a crater of unvarying shape, and should be correctly aligned. The management of a searchlight demands considerable skill, and the large number used for home defence has entailed a demand for operators with electrical knowledge, which, fortunately, our technical colleges have been able to meet.

Periscopes.

The common article sold at many shops for use in the trenches, and consisting of two mirrors mounted in a frame and inclined at 45°, is an old invention which used to be called the "polemoscope," but is now wrongly termed a periscope. Strictly speaking, a periscope is an instrument in which the whole surroundings of an observer may be viewed through a fixed eye-piece. For naval work, and particularly for submarines, these instruments are invaluable, as observations may be made with nothing but the top of the instrument projecting above the water. A periscopic gun-sight also enables guns to be laid behind cover, and enables auxiliary marks to be used without the gunner having to

change his position. The principle of the periscope is shown in Fig. 4, in which the path of the central ray is indicated. The upper prism A is mounted on a cowl, so as to be

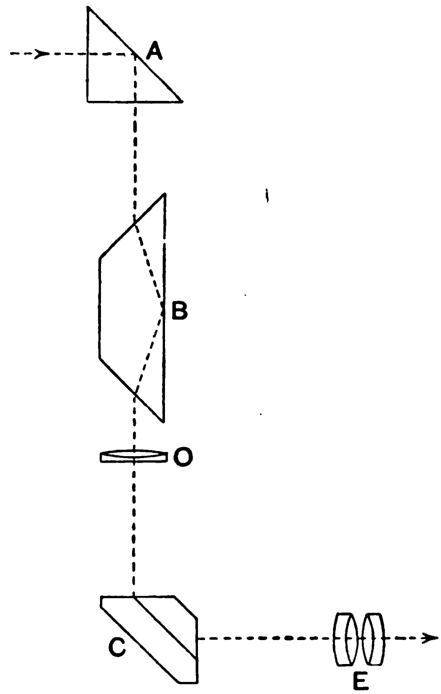

Fig. 4.

capable of revolution in a circle. Rays from the object are reflected from its sloping face into a second prism B, the longer vertical face of which acts as reflector. The rays then pass through the object-glass O, and thence through a third prism C, known as a "roof" prism, which turns the rays at right angles into the eyepiece E. The prism A inverts the rays vertically, but by passing through B, which also inverts vertically, this effect in A is counteracted and an upright image enters the object-glass O. This lens inverts the rays both horizontally and vertically, but the prism C, in which two reflexions occur, restores the rays to the original directions, and hence a correct image is viewed by the eyepiece, which magnifies without causing inversion in either direction. When the prism A is revolved, B is caused by an attached mechanism to move at one half the rate, and as the angular movement of a ray is twice that of the mirror which produces it, the rays will always fall on the object-glass in the same direction, whatever may be the position of A. The upper prism may be placed at the end of a tube at any desired height above the observer.

Many modifications of the above arrangement exist in periscopes of different makes; the general principle, however, is the same.

Range-Finders.

The first range-finder of which I have been able to discover a record was designed by James Peacock, architect, of Finsbury Square, and published in a book entitled "A Repertory of Arts, Manufactures and Inventions" in 1794. This range-finder is interesting from the fact that it is a "one-man" instrument, with a short base, relying for its accuracy on optical perfection—resembling in this respect the most recent instruments. The principle is indicated in Fig. 5, where AG is a scale to one end of which is fixed a flat mirror F, inclined at 45° to the edge of the scale. A telescope T is fixed at right angles to the lower edge, so that its cross-wire is exactly opposite the end. At the other extremity of the scale is placed a second flat mirror E, fixed at a definite angle, but capable of horizontal motion along the scale. In marking the scale to read ranges, it was proposed to light a candle at one end of General Roy's five-mile base and to view the light through the telescope from the other end of the base, the upper portion of F being left unsilvered for this purpose. The mirror E was then to be tilted so that the reflected image, after falling on the silvered part

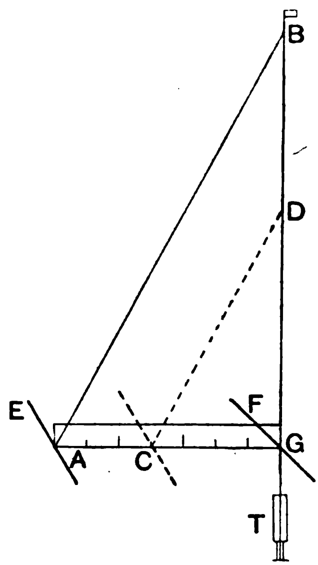

Fig. 5.

of F and passing into the telescope, was exactly in line with the direct image, in which position it was to be securely fastened so as to retain its inclination. The extremity of the scale A was

then to be marked five miles, and G zero, the part in between being divided into equal divisions of any desired size. The range could then be read off directly by observing the position of E when the images coincided; thus the range GD would be represented by CG on the scale, since $\frac{GD}{GB} = \frac{CG}{AB}$. It was suggested that the instrument would be useful to surveyors—in those days the accurate, long-range gun had not been invented—but there is no mention of its actual manufacture. The idea, however, is sound; and with modern appliances might probably be worked up into a satisfactory range-finder.

In the demand for range-finders, caused by modern guns, the instruments at first used—and not yet entirely extinct—required two observers, and a long base was adopted with a view to accuracy. The service "mekometer" (Fig. 6) is an example of this type. An observer

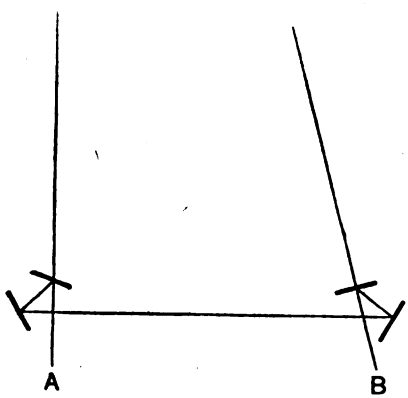

Fig. 6.

stationed at A uses an instrument containing two mirrors inclined at 45° to each other, the upper mirror being unsilvered in its upper portion. On looking at this mirror he sees the target through the upper part directly, and, by reflexion, a white mark on the instrument of the second observer. When target and mark appear in line, the base is at right angles to the target. The observer at B uses a similar instrument, except that the lower mirror may be moved by a milled-head, which must be turned until the target coincides with the white mark on the instrument at A. The angle could then be determined and the triangle solved; but to save calculation the range is marked directly on a drum which rotates with the milled-head. The base used is 25 or 50 yards long, according to pattern, and consists of a stout cord with hooks at the end to fasten to the instruments. Simple as the mekometer seems, it is not easy to obtain very accurate results by its use. The cord cannot be pulled perfectly straight, and variations in the amount of droop alter the result. Small errors in aligning the target and the white mark also cause notable errors in the reading, and it is not uncommon for beginners to return results varying by 20 per cent., even when using the same instruments and target. Two skilled observers, however, using a 50-yards base-cord, should take a range of 2,500 yards with an error not exceeding 2 per cent.

The "Field Telemeter" consists of a single instrument, but requires two men to use it in taking a range. It differs from the mekometer in the respect that a base of any suitable length may be used. The actual length of the base chosen for the occasion is measured by the instrument, the standard of reference being a steel tape 6 or 9 yards long, according to the pattern. This tape is run out at right angles to the base at one end, and serves as a sub-base for the measurement of the working base. A sliding collar, moving over a graduated bar, is then set at the figure corresponding to the measured base, the position of this collar determining the amount of angular movement imparted to the movable mirror by the adjusting-screw. The range is read off from a drum which rotates with the adjusting-screw; and whatever length of base be chosen, the same figure will be obtained, provided the sliding collar be correctly set on the bar. A detailed description of this instrument would not be possible within the limits of the present paper. It may be stated, however, that the field telemeter is superior to the mekometer, particularly for long ranges; and practised observers can obtain readings up to 5,000 yards with an error not greater than 2 per cent. The Watkin Field Range-Finder is a similar instrument.

All range-finders requiring two observers and the setting out of a base-line suffer from the defects, (1) that a considerable time—possibly five minutes—is required to obtain the range; and (2) that the ranges of moving objects cannot be taken continuously. For these reasons, both for naval and military use, "one-man" range-finders are found preferable. The type introduced by Professors Barr and Stroud is now generally employed, and gives very satisfactory results, although its construction is more delicate than that of "two-men" instruments.

Fig. 7 indicates the arrangement of parts in the Barr and Stroud range-finder, which consists of two telescopes with a single eyepiece. Rays from the distant object enter the five-sided prism A through a window, and as the sides of this prism are inclined at 45° the emerging ray escapes at right angles to its original path and passes through the objective O to the central reflecting prisms R, from whence it enters the eyepiece E. The rays entering the right-hand prism B follow a similar course through the objective; but, owing to the length of the tube, such rays will enter B at a different angle to which rays from the same point enter A, and will pass through the tube inclined to the horizontal. This inclination will evidently vary with the distance of the sighted object; and, if the rays were permitted to pass unchanged to the central reflectors, and so to the eyepiece, the image of the object would not coincide with that formed by the system on the left. By interposing an adjusting-prism P in the path of the inclined rays, however, they may be turned into a horizontal position, when coincidence of the images will occur. The correct position of P depends upon the inclination of the rays which enter it—that is, upon the distance of the target; and hence this position may be used to define the range by attaching a range scale S to P, and noting the reading opposite a fixed point.

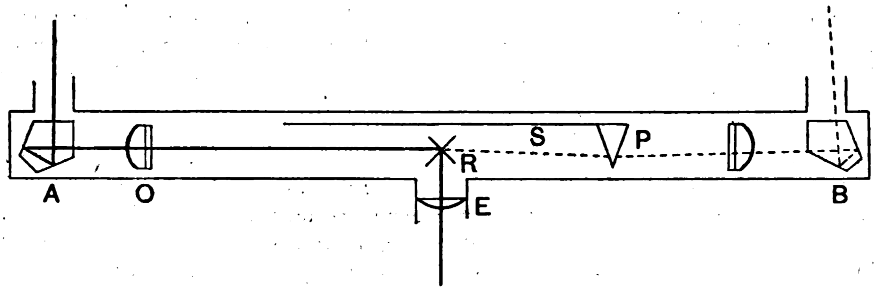

FIG. 7.

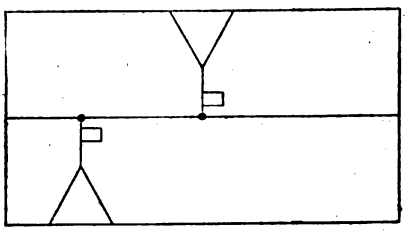

FIG. 8.

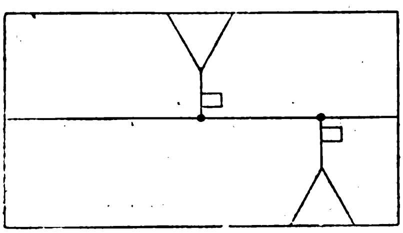

FIG. 9.

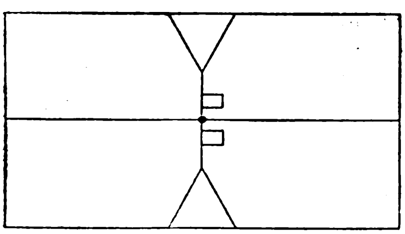

FIG. 10.

The method of obtaining coincidence is indicated in Figs. 8, 9, and 10. The arrangement of the central prisms is such that the image due to the left-hand telescope is inverted, whilst that formed by the right-hand side is erect, both being seen in the eyepiece divided by a central line. In Fig. 8 the adjusting prism is too near the centre, and gives an image displaced to the left; in Fig. 9 it is too far away from the centre, the image now being too far to the right; whilst Fig. 10 shows the correct position, the images being coincident. In the actual instrument, a second lens is provided near the eyepiece, through which the range may be viewed simultaneously with the image. The following are some particulars of the instrument: Total length, 44½ in.; working base, 1 metre; weight, 13½lb.; magnification of telescope, 13; field of view, horizontal, 3° 10′; field of view, vertical, 2° 40′; range scale graduated from 500 to 20,000 yards; accuracy, 2½ per cent. at 5,000 yards. Readings at the highest ranges are only approximations. General experience with the Barr and Stroud range-finder is entirely in its favour, and shows it to be superior to the types which require two observers.

The Zeiss range-finder differs from the Barr

and Stroud in the construction of the adjusting-prism, which, in the Zeiss pattern, consists of two wedges of glass rotated in opposite directions by a gearing, the deviation of the ray being thereby changed as desired. The same movement actuates the range-scale in front of a fixed pointer, opposite which the range is read off after adjustment. This gives a small total length of scale, and in this respect is inferior to the Barr and Stroud.

In the Marindin range-finder the five-sided prisms are replaced by right-angled prisms, which carry the object-glasses on their upper surfaces, facing the target. Each reflects the image from its hypotenuse to the central prisms, from whence they pass into the eyepiece. Adjustment to coincidence is obtained by turning a drum on which the scale is marked, and which at its forward end engages a lever fastened to the right-hand prism, which is thereby tilted and alters the position of the image in the eyepiece. The range is read directly from the drum. This instrument, used by infantry, reads up to 8,000 yards, the error at 2,000 yards not exceeding 5 per cent.

The Zeiss stereo-telemeter depends on stereoscopic vision, and has been used to some extent in our own Army as well as the German. A pair of transparent plates are placed in a binocular, one in each eyepiece, forming a stereoscopic couple. On these plates are marked arrows pointing downwards in three zig-zag lines. Each corresponding pair gives a single image in relief, and as no two pairs are the same distance apart, the appearance presented is that of a number of arrows overhanging the landscape at progressive distances from the eye. In taking a range, the observer must decide which of the arrows overhangs the target; the distance is then taken as that marked against this arrow. The arrows are marked from 90 to 3,000 metres; but the accuracy depends upon the eyesight of the observer, which should be good and equal in both eyes—a condition which reduces the number of reliable operators to about 20 per cent. of an average body of men. If this condition be fulfilled, the error will not exceed 1 per cent. at 1,000 yards, or 4 per cent. at 5,000 yards.

Signalling Devices.

In trench warfare signalling by flags, heliograph, or lamps is not greatly resorted to, the field telephone being better adapted for communications under these conditions. In open warfare, however, the heliograph is useful for flashing signals by the aid of sunlight. It consists of a circular flat mirror, 5 in. in diameter, capable of being tilted through a small angle by means of a key, and possessing a sighting-vane for laying on to the receiving station. The Morse code is used, short flashes representing dots, and a sustained flash dashes. For night work signalling lamps are used, a parallel beam of light being sent out, which can be cut off by a movable shutter. Some lamps burn oil, others acetylene, and a strong lens is used to produce the parallel beam.

Conclusion.

It is evident from the foregoing descriptions that optical devices, often of a type which requires great precision in the making, play an important part in modern warfare. An unforseen demand for these instruments has arisen and it is gratifying to know that our opticians are responding well to the call. The steps that have been taken to secure an adequate supply of the right kind of glass were described recently by Dr. Rosenhain in his Cantor Lectures before this Society. We have allowed Germany to get a long way ahead of us in some respects in relation to optical appliances, and for a simple reason. In Germany manufacturers and men of the highest scientific attainments have co-operated; in this country they have not. The commercial realisation of an idea is quite a different matter to its mere inception; and unless our best scientific men are willing to give some of their time to production, and not confine themselves to research in so-called "pure" science, there is little hope of improvement in the future. Manufacturers have received plenty of advice but no practical help in the past. A step in the right direction would be greatly to extend the scope and activities of the National Physical Laboratory, so as to enable it to assist in problems of production in the case of industries of a highly scientific character, of which optical appliances form a characteristic example.

Another matter, referring to recent conditions, will be obvious. Every officer who may be called upon to use scientific instruments should receive a scientific training to enable him to use them properly. For many years past it has not been deemed necessary to impart a knowledge of science to infantry and cavalry officers, so that it became a tradition that science was only of use to the "sapper" and the "gunner." Experience in the present war has proved that every officer, whatever branch of the Service he may belong to, would be able to serve his country better if he received a training in science.

Using instruments according to drill regulations only is of very limited service; for in the presence of a small defect which could easily be remedied by one who understands an instrument, the mere automaton would be helpless. On the occasion of a lecture on "Field Telephones," delivered before the Society in July last, I appealed for the services of science teachers to be utilised in teaching that subject, and since that time much useful work has been done and is still in progress. I would extend that appeal so as to include all branches of military science that may be taught successfully at a college or technical school. Advantage could be taken of the buildings and equipment, and members of the staffs would be found willing to devote any spare time to the work. Taking the instruments described in the present paper as typical, a few experimental lessons would suffice to give intelligent men an insight into the working which could never be obtained by mere drill, and co-operative action on these lines between the military and educational authorities could not fail to increase the efficiency of our Army.

[Examples of modern optical appliances for naval and military purposes were exhibited by Messrs. Ross, Ltd., and by Messrs. R. & J. Beck, Ltd.]

DISCUSSION.

THE CHAIRMAN (Dr. R. T. Glazebrook) said the audience would agree that the author was to be congratulated on the manner in which he had been able to describe the principles of the working of optical apparatus, which was now of fundamental importance in the war. It was of advantage that everyone should realise and appreciate the difficulties that had had to be overcome by the direct applications of optical science and other branches of science. There was no doubt whatever as to the importance of the matter dealt with, and as to the necessity for everyone interested to combine to render the instruments even more perfect and more satisfactory than they were at present. With regard to the original form of range-finder, he would suggest that if any members of the audience were interested in instruments of that kind they would find a great deal of very valuable and useful information in a little pamphlet recently republished by Mr. Cheshire, of the Ministry of Munitions. With regard to instruments generally, he could cordially substantiate all the author had said about the excellence of the quality of the instruments that were now being made for the Services. Many of the instruments for the Navy passed through his own hands, and he had sometimes to deal with other instruments, and there was no doubt whatever that they were now of a very high degree of perfection, and a debt of gratitude was owing to English optical instrument-makers for the care and attention they had devoted to the work. At the same time, he could not help thinking there was a somewhat sad history attached to many of them. Reading the paper, it would be seen that in too many cases the author began with a simple instrument, an excellent instrument of its time, of English manufacture, and, after tracing the development of that instrument, nearly always ended up with a German name. One striking exception to that rule was the Barr and Stroud range-finder, which was of English invention and English manufacture; but even then the author passed from the Barr and Stroud to a special form of Zeiss instrument. It was to be hoped that one of the results that would follow from a consideration of the subject after the war would be the careful thought and careful development by instrument-makers of the theory of the instruments they were making and of the principles that underlay the theory. He wished it were possible to see established in London an institution for which he, amongst others, had pleaded for many years past, devoted to the teaching of higher optics as applied to instruments of all kinds, but especially as applied to instruments of war, teaching that would include not only the theory of the instruments but the practical details of their manufacture. Such an institution was most urgently needed, and it would be a crying shame if, within the near future, it was not established in London on a satisfactory and lasting basis.

MR. F. CHESHIRE said as far as he was aware the first practical range-finder was one that was invented in the latter half of the eighteenth century by a German named Brander. The instrument was well designed and capable of reliable work. He was pleased to say that at the present time the Barr and Stroud range-finder for field use was, in his opinion, the best in the world. On the Continent it had beaten the range-finders made by the best German makers. The accuracy of the instrument, taking into consideration the conditions under which it was used, was phenomenal. The author, in referring to the prismatic binocular, stated that one great advantage of the instrument was that it allowed the use of an objective of great focal length. When the prismatic binocular was introduced it was almost impossible to obtain ordinary terrestrial telescopes with a smaller magnification than fifteen. Galilean binoculars, on the other hand, could not be made efficient with a greater magnification than about five. The great merit of the prismatic binocular was that it filled up the gap between the opera-glass and the ordinary terrestrial telescope—that is, it gave magnifications between five and fifteen. Previous to the introduction of the prismatic binocular many attempts had been made to couple together two

ordinary terrestrial telescopes to obtain a binocular instrument, but these attempts had failed largely because it was found impossible to secure and maintain the necessary order of accuracy of the parallelism of the axes of the two telescopes. The prismatic binocular being a much shorter instrument enabled a hinged connection to be made which was efficient in maintaining the necessary parallelism of the axes. With regard to the author's mention of a telescope which had the magnifying power of one when looked through in one direction and a magnifying power of three when looked through in the other direction, he thought that some mistake had been made. If Mr. Beck had really made such a telescope he had certainly not submitted it to the Ministry of Munitions. So far, all telescopes that he had any acquaintance with had a magnifying power when looked through in one direction which was the reciprocal of that obtained by looking through it in the other.

MR. CHARLES DARLING said the instrument he had referred to was not a telescope but a periscope, and he understood it was so arranged that it was possible to get a direct view unmagnified by looking through one window and a three-time magnification by looking through another window.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to the author for his paper, and the meeting terminated.

CORRESPONDENCE.

A PIONEER IN AVIATION.

In your *Journal* of December 10th, 1915, No. 3290, Vol. LXIV., is published, under the heading "A Pioneer in Aviation," a biography of Lawrence Hargrave, Australia's pioneer of aviation.

I was very pleased to find this eulogium of so fine a worker in the field of applied science, and I would like to thank you for its insertion.

Now, it may interest your readers to know that in this museum are housed, in a very large plate-glass showcase—the largest in the museum—a complete series of Hargrave's original models of his monoplanes, those used to illustrate his papers read before our Royal Society on flying machines.

I notice you state "It is not to our credit that when, some years ago, Mr. Hargrave offered to hand over all his models to the Australian Government, so that they might be available for inspection by other inventors and the public generally, they could find no room for them anywhere. The same indifference was shown in England. So they were presented to Germany, and to-day they may be seen in the Deutsche Museum at Munich, and it is believed that the 'Taube' aeroplane, which has been so prominent in the war, is fashioned on one of these Australian models."

My object in writing is to point out that these remarks do not apply to the Government of New South Wales, for this museum's records show that in 1909 he offered to the Government of New South Wales, through the Premier, his models of box kites, leading up to his biplane machines. His offer was submitted to me, and I recommended the Government of that day to accept these particular models, and so make the series of his inventions complete in this museum. The Minister for Public Instruction also recommended their acceptance, and an excerpt from the Premier's final minute states: "Accommodation will be found in the Technological Museum." I do not think they were offered to any other Australian Government.

I always regretted Lawrence Hargrave's action in this matter, and I am afraid a writer at the time accounted for his death in the words: "But I know that the German bullet that killed his only son, killed Lawrence Hargrave."

RICHARD T. BAKER,
Curator.

The Technological Museum,
Harris Street, Sydney.
January 25th, 1916.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

MARCH 15.—EDWARD PERCY STEBBING, F.L.S., F.R.G.S., Head of the Department of Forestry, University of Edinburgh, "Forestry and the War."

MARCH 22.—REV. P. H. DITCHFIELD, M.A., F.S.A., "The England of Shakespeare." HUBERT HALL, F.S.A. (Public Record Office), will preside.

MARCH 29.—R. W. SETON-WATSON, D.Litt., "Pan-German Aspirations in the Near East."

APRIL 5.—ARTHUR S. JENNINGS, "Painting by Dipping, Spraying, and other Mechanical Means."

MAY 3.—PROFESSOR W. B. BOTTOMLEY, M.A., F.C.S., F.L.S., "Bacterised Peat."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

APRIL 6.—PROFESSOR WYNDHAM R. DUNSTAN, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India." THE RIGHT HON. LORD ISLINGTON, G.C.M.G., will preside.

APRIL 27.—JAMES MACKENNA, M.A., I.C.S. (Deputy Commissioner, Myaungmya, Burma, and designated Agricultural Adviser to the Government of India), "Scientific Agriculture in India."

MAY 18.—SARDAR DALJIT SINGH, C.S.I., "The Sikhs."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m. :—

MARCH 28.—PERCY HURD, "Next Steps in Empire Partnership."

APRIL 11.—SIR DANIEL MORRIS, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland." The Right Hon. SIR WILLIAM MACGREGOR, P.C., G.C.M.G., C.B., will preside.

Dates to be hereafter announced :—

JOHN COLLETT MOULDEN, A.R.S.M. M.Inst.M.M., "Zinc, its Production and Industrial Applications." (Peter Le Neve Foster Prize Essay.)

VICTOR HORTA, Directeur de l'Académie Royale des Beaux-Arts de la Ville de Bruxelles, "Belgian Architecture."

G. P. BAKER, "Hindu Hand-painted Calicoes of the Seventeenth and Eighteenth Centuries, and their Influence on the Tinctorial Arts of Europe."

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m. :—

J. ERSKINE-MURRAY, D.Sc., F.R.S.E., M.I.E.E., "Vibrations, Waves, and Resonance." Four Lectures.

May 1, 8, 15, 22.

FOTHERGILL LECTURES.

Monday afternoons, at 4.30 p.m. :—

EDWARD A. REEVES, F.R.A.S., F.R.G.S., Map Curator and Instructor in Surveying to the Royal Geographical Society, "Surveying, Past and Present." Three Lectures.

March 27, April 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 13 ... Economics and Political Science, London School of, Clare-market, W.C., 5 p.m. Hon. W. P. Reeves, "The Balkan States." (Lecture VI.)

Brewing Institute of (London Section), Imperial Hotel, Russell-square, W.C., 8 p.m. Mr. S. W. Cole, "The Cleansing of a Brewery."

TUESDAY, MARCH 14...Sociological Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.15 p.m. Mr. P. Mantoux, "The Influence of the War on the Problem of the Individual and the Social Factor in Historical Causation."

Colonial Institute, Hotel Cecil, Strand, W.C., 8.30 p.m. Mr. B. H. Morgan, "The Necessity for a Common Imperial Economic Policy."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. Keith, "Sea Power as a Factor in the Evolution of Modern Races." (Lecture I.)

British Decorators, Institute of, Painters' Hall, Little Trinity-lane, E.C., 8 p.m. Mr. A. Wilcock, "Coloured and Patterned Draperies in Decoration."

Electrical Engineers, Institution of (Scottish Section), 207, Bath-street, Glasgow, 8 p.m. Dr. C. Chree, "Terrestrial Magnetism."

WEDNESDAY, MARCH 15... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Professor E. P. Stebbing, "Forestry and the War."

University of London, King's College, Strand, W.C., 5.15 p.m. Mr. L. B. Namier, "The Poles in their relation to Vienna and the Austrian Slavs."

Meteorological Society, at the Surveyors' Institution, 12, Great George-street, S.W., 7.30 p.m. Sir Napier Shaw, "The Meteorology of the Globe in 1911."

Electrical Engineers, Institution of (Local Section), The University, Birmingham, 7 p.m. Mr. N. W. Storer, "The Use of Continuous Current for Terminal and Trunk Line Electrification."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5.15 p.m. Professor W. L. Courtney, "Dramatists and War.—I. Aristophanes."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 5.30 p.m. Mr. W. G. Perkins, "Some Examples of Dangerous Structures."

THURSDAY, MARCH 16...Royal Society, Burlington House, W., 4.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. The President, "Resemblance between African Butterflies of the genus *Charaxes*: a new form of Mimicry." 2. Mr. C. C. Lacaita, "Notes on Plants collected in Sikkim, including the Kalimpong District." 3. Mr. E. Bunyard, Exhibition of Species of *Ribes* and their garden derivation. 4. The General Secretary, "Early Botanical Exploration of North America."

Child Study Society, 90, Buckingham Palace-road, S.W., 6 p.m. Dr. E. Jones, "The Unconscious Mental Life of the Child."

Chemical Society, Burlington House, W., 8 p.m. 1. Mr. W. R. Innes, "Molecular association." 2. Mr. T. J. Drakeley, "The influence of iron pyrites on the oxidation of coal." 3. Mr. G. W. Hargreaves, "The essential oil of Cinnamomum Oliveri (Bail) or Brisbane Sassafras."

Royal Institution, Albemarle-street, W., 3 p.m. Professor H. E. Armstrong, "Organic Chemistry in War—Organic Products used as Propulsive and Explosive Agents." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Dr. G. H. Rodman, "The Bernese Oberland."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Mr. N. W. Storer, "The Use of Direct Current for Terminal and Trunk Line Electrification."

Historical Society, 22, Russell-square, W.C., 5 p.m. Mr. J. F. Chance, "Germany in the Time of George I."

Numismatic Society, 22, Albemarle Street, W., 6 p.m. Mr. L. A. Lawrence, "More Chronology of the Short-Cross Period."

FRIDAY, MARCH 17 ... London Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Mr. A. Moor-Radford, "Kensington—Past and Present."

Royal Institution, Albemarle-street, W., 5 p.m. Dr. A. Strahan, "The Search for New Coal Fields in England."

University of London, at the London School of Economics and Political Science, Clare-market, W.C., 5 p.m. Mr. C. Turnor, "The Land and the Empire." (Lecture II.)

Mechanical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. Second Lieut. R. W. Fenning, "The Composition of the Exhaust from Liquid fuel Engines."

SATURDAY, MARCH 18...Royal Institution, Albemarle-street W., 3 p.m. Professor Sir J. J. Thomson, "Radiations from Atoms and Electrons." (Lecture II.)

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—March 10, 1916.

Journal of the Royal Society of Arts.

No. 3,304. VOL. LXIV.

FRIDAY, MARCH 17, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

Wednesday, March 22nd, 4.30 p.m. (Ordinary Meeting.) Rev. Peter Hampson Ditchfield, M.A., F.S.A., "The England of Shakespeare." Hubert Hall, F.S.A. (Public Record Office), will preside.

Further particulars of the Society's meetings will be found at the end of this number.

JOURNAL.

The Government limitations on the importation of paper and paper-making materials have rendered it necessary to restrict the *Journal* to the smallest possible size. For the present, therefore, its contents will be confined as far as possible to a report of the actual proceedings of the Society, and it may be necessary occasionally to publish reports of the meetings a little less promptly than has always been the practice.

It is hoped that the Fellows will appreciate the necessity of such restrictions, and it is also hoped that the *Journal* may be able to expand to its normal size at an early date.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal of the Royal Society of Arts for 1916 early in May next, and they therefore invite members of the Society to forward to the Secretary on or before Saturday, March 25th, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce," and has been awarded as follows in previous years :—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S.

In 1865, to his Imperial Majesty, Napoleon III.

In 1866, to Michael Faraday, D.C.L., F.R.S.

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S.

In 1868, to Mr. (afterwards Sir) Joseph Whitworth, LL.D., F.R.S.

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, etc.

In 1870, to Vicomte Ferdinand de Lesseps, Member of the Institute of France, Hon. G.C.S.I.

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B.

In 1872, to Mr. (afterwards Sir) Henry Bessemer, F.R.S.

In 1873, to Michel Eugène Chevreul, For. Memb. R.S., Member of the Institute of France.

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S.

In 1875, to Michel Chevalier.

In 1876, to Sir George B. Airy, K.C.B., F.R.S., Astronomer Royal.

In 1877, to Jean Baptiste Dumas, For. Memb. R.S., Member of the Institute of France.

In 1878, to Sir Wm. G. Armstrong (afterwards Lord Armstrong), C.B., D.C.L., F.R.S.

In 1879, to Sir William Thomson (afterwards Lord Kelvin), O.M., LL.D., D.C.L., F.R.S.

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S.

In 1881, to August Wilhelm Hofmann, M.D., LL.D., F.R.S., Professor of Chemistry in the University of Berlin.

In 1882, to Louis Pasteur, Member of the Institute of France, For. Memb. R.S.

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S.

In 1884, to Captain James Buchanan Eads.

In 1885, to Mr. (afterwards Sir) Henry Doulton.

In 1886, to Samuel Cunliffe Lister (afterwards Lord Masham).

In 1887, to Her Majesty Queen Victoria.

In 1888, to Professor Hermann Louis Helmholtz, For. Memb. R.S.

In 1889, to John Percy, LL.D., F.R.S.

In 1890, to Dr. (afterwards Sir) William Henry Perkin, F.R.S.

In 1891, to Sir Frederick Abel, Bart., G.C.V.O., K.C.B., D.C.L., D.Sc., F.R.S.

In 1892, to Thomas Alva Edison.

In 1893, to Sir John Bennet Lawes, Bart., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S.

In 1894, to Sir Joseph (afterwards Lord) Lister, F.R.S.

In 1895, to Sir Isaac Lowthian Bell, Bart., F.R.S.

In 1896, to Professor David Edward Hughes, F.R.S.

In 1897, to George James Symons, F.R.S.

In 1898, to Professor Robert Wilhelm Bunsen, M.D., For. Memb. R.S.

In 1899, to Sir William Crookes, O.M., F.R.S.
In 1900, to Henry Wilde, F.R.S.
In 1901, to His Majesty King Edward VII.
In 1902, to Professor Alexander Graham Bell.
In 1903, to Sir Charles Augustus Hartley, K.C.M.G.
In 1904, to Walter Crane.
In 1905, to Lord Rayleigh, O.M., D.C.L., Sc.D., F.R.S.
In 1906, to Sir Joseph Wilson Swan, M.A., D.Sc., F.R.S.
In 1907, to the Earl of Cromer, O.M., G.C.B., G.C.M.G., K.C.S.I., C.I.E.
In 1908, to Sir James Dewar, M.A., D.Sc., LL.D., F.R.S.
In 1909, to Sir Andrew Noble, K.C.B., D.Sc., D.C.L., F.R.S.
In 1910, to Madame Curie.
In 1911, to the Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., D.Sc., F.R.S.
In 1912, to the Right Hon. Lord Strathcona and Mount Royal, G.C.M.G., G.C.V.O., LL.D., D.C.L., F.R.S.
In 1913, to His Majesty King George V.
In 1914, to Chevalier Guglielmo Marconi, G.C.V.O., LL.D., D.Sc.
In 1915, to Professor Sir Joseph John Thomson, O.M., D.Sc., LL.D., F.R.S.

A full list of the services for which the medals were awarded was given in the last number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

FOURTEENTH ORDINARY MEETING.

Wednesday, March 15th, 1916; John Slater, F.R.I.B.A., Member of the Council of the Society, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Kewley, James, M.A., Cambrian Lodge, Portishead.
Walker, Basil Woodd, M.D., 6, Dawson-place, Pembridge-square, W.

The paper read was—

FORESTRY AND THE WAR.

By Edward Percy Stebbing, F.L.S., F.R.G.S.

It is not perhaps generally known that two and a half centuries ago, at the commencement of the reign of Charles II., this country was in a somewhat similar position, as regards afforestation and timber supplies, to the one existing at the present day.

At the period in our history to which I allude the devastating Civil War had but recently terminated. Great inroads into the existing forests had commenced after Henry VIII. had taken possession of the Church lands and converted them, together with their woods, to his own use. But at that time the whole kingdom was well wooded and the forests were not seriously impaired. During the Civil War, however, both the Royal Forests and those of the landed proprietors suffered very severely, many large woods being razed to the ground; their names only remaining in the localities as a proof of their former existence.

So serious had the position of affairs become that in the early years of the reign of Charles II. grave anxiety was expressed by the State Commissioners on the score of the supply of oak timber so essential for the upkeep of the "wooden walls"—in other words, the Navy, which then, as now, formed the bulwark of the country.

In 1662 the Royal Society was founded under the patronage of the King. From its inauguration, as throughout the two and a half centuries which have elapsed since that date, the Society placed the welfare of the nation in the forefront of its activities. The grave position of the oak timber supplies having been brought to the attention of the Council, they deputed one of the Society's first Fellows and Members of Council, Mr. John Evelyn, to prepare a treatise on the subject. Thus originated that great work by which Evelyn is perhaps best known, his "Sylva," or, as he terms it in an alternative title, "A Discourse of Forest Trees and the Propagation of Timber in His Majesty's Dominions." This discourse was read before the Royal Society on October 15th, 1662, and published by the Society two years later. From a forester's point of view this work is above all criticism. It stands as a lasting memorial to a highly gifted and far-seeing man, whilst at the same time giving us a clear insight into the extensive knowledge on the subject of tree-planting and all connected with it existing at the period.

But the after-results of this action on the part of the Society are even more interesting, and their significance should not be lost to us at the present time. Evelyn effectually awoke the interest in planting he set himself to secure; for in the dedication to the King in his fourth edition, published in 1678 (fourteen years after the "Sylva" first appeared), he records the fact that many millions of trees had been planted both in the Royal Forests and in privately owned ones as the direct outcome of the action of the Royal Society—a result publicly acknowledged by the King. We now come to the most interesting sequel.

A century later, in 1776, Dr. A. Hunter, F.R.S., edited a new edition of the "Sylva." In his preface he has the following remarks: "Soon after the publication of the 'Sylva' the spirit for planting increased to a high degree, and there is reason to believe that many of our ships which, in the last war, gave laws to the whole world, were constructed of oaks planted at that time."

It may be regarded, then, as tolerably certain that the oak timber required for the ships, or of which, I may say, the ships were built, which fought and won the battle of Trafalgar, was present in this country at the hour of its dire need as the direct outcome of the action of the Royal Society and the influence of the "Sylva."

Soon after its formation in 1754 the Royal Society of Arts energetically took up the question of planting, and instituted a system of premiums and medals to be awarded to those sowing and planting up the greatest areas of land. Between 1758 and 1821, 127 gold and 40 silver medals were awarded in this way, in addition to pecuniary premiums. As a result of this enlightened policy a considerable amount of planting was carried out during this period.

The grim spectre of invasion receded for a century after Trafalgar. The "wooden walls" disappeared and were replaced by steel ones. We had secured unquestioned command of the seas, and with the improved steam communication home forestry, which had been neglected to some considerable extent, began to decline rapidly. This decline proceeded at a quicker rate when the import duty was taken off colonial timber in 1846, and the removal of these duties from all foreign timber in 1866 may be said to have sounded the death-knell of British commercial forestry. Although it had been a profitable rural industry for centuries in this country, it became unprofitable. It was not that the industry would not still pay. It was simply that the old English methods of growing timber, which dated from 1540 or thereabouts, and which in that period had spread throughout this island and across into Ireland, no longer provided the clean stems free from knots required by the market. The markets had changed, and we continued on the old lines growing material for which there was no demand. Practically throughout the latter half of the last century the woods came to be looked upon chiefly from the point of view of game coverts and ornaments to large estates. We depended almost entirely on imports for our supplies of forestry materials. In 1913, the last year of which we have full returns before the war, we imported £43,000,000 sterling worth of forestry materials. In what position did the Great War find us in respect of these materials? The United Kingdom contained an odd three million acres of woodlands, for the most part kept up either for shelter or sport, and to a lesser extent for ornament. A certain proportion of this area was useless scrub. Two to three per cent. of these woods belonged to the Crown. The State owned no woods in Great Britain.

These woods had not, for the most part, in recent years been worked upon commercial principles. And the only forestry which pays is commercial forestry. We shall return to this point later on.

This brings us to the present time. The war caught us totally unprepared. The mines felt the position at once. Pit wood rose to famine rates, and many mine-owners are likely to remember the worries of August, 1914, and subsequently. Of course our hope lay in the Navy. The Navy was to see that we got all we wanted in imports. But we had not foreseen, or would not foresee, that even with the command of the seas a European war might close up the chief sources of our supplies. And yet this, in combination with an insufficiency of freight ships, is what has taken place.

Nor, apparently, did we foresee that in the absence of adequate supplies grown at home we should have no hold over the market and prices. What is the present position? We have spent large sums of money on timber for Naval and War Office purposes—money which has gone, for the most part, into the pockets of neutrals. Prices have reached a level which would have been regarded as incredible before the war. We are now engaged in cutting down, in sacrificing, such woods as we have in this country. And we have, say, some 5,000,000 to 9,000,000 acres of land in these islands which expert opinion is unanimous would grow timber, and a considerable proportion of which would carry fine crops of commercially profitable timber trees.

It is not, however, a consideration of what might have been which should occupy our energies at present. The two problems as they appear to present themselves are: (1) The present position of timber supplies and the position which will face the Allied Powers at the close of the war; (2) What should the country do to ensure that our posterity shall not have to face a position similar to the one confronting us to-day?

(1) The present position of timber supplies and the position which will face the Allied Powers at the close of the war.

The present prices of timber are inordinately high. In this country the following rates are in force for the materials in common use, as compared with pre-war prices :—

PRE-WAR PRICES COMPARED WITH PRESENT PRICES.

Comment on the above figures is scarcely necessary. They are a direct outcome of two facts—the first, an almost total lack of interest on the part of the nation as a whole in all pertaining to the economic questions involved in commercial forestry and the maintenance in these islands of that acreage of woods managed commercially which our population and industries demand; and, secondly, to the failure on the part of the Governments of the past fifty years, to go back no further, to realise the position in this respect which would confront the nation in the event of just such a European conflagration as has taken place. The Government existing in this country 250 years ago was more clear-sighted. True, it may be said that our "wooden walls" of that day and the necessity for maintaining them were factors which both Government and the public could more easily grasp. But no Government of the present day would care to shelter itself behind such a plea. Our economic needs in timber are far greater now. We have only to look at the gigantic imports—they rose by twelve million pounds in the four years from 1909 to 1913—to realise this.

But we are not concerned with "might have beens." The point is, where are we to look for supplies, and, having found them, what steps should be taken to ensure that they shall be fully utilised at reasonable prices at the end of the war? It appears imperative that this question should be solved, and solved in time.

What is the present position of affairs in Europe? Incalculable devastation has been committed in the areas in which the war is being waged. Countless families are homeless. Building on a stupendous scale will require to be undertaken. Where is the timber required for

this new construction work to come from? And what price is to be paid for it? Is the end of the war to witness a ruinous competition between the Allied countries in the timber markets of Europe? And are colossal sums to be spent, colossal fortunes to be made, in rebuilding the devastated cities, towns, and homesteads which war has destroyed?

This is one direction in which a definite understanding should be come to between the Allies before the war terminates.

On what lines should an understanding of this nature proceed? It may be contended that the end of the war will witness the re-opening of the ports and a resumption of the timber exports without the interference of Government. This, it is to be hoped, will take place, but it will not bring down prices. We see congratulatory remarks made on the assistance which America, Canada, and Newfoundland are giving by the large consignments of timber, wood pulp, etc., they are sending us. But the supplies are the outcome of the high prices. Heavy fellings are being made in our own woods under the auspices of the Home Timber Committee in order to supplement these imports. Lord Selborne's well-timed action in appointing the Home Timber Committee was wise. There are two points in connection with these home timber fellings, however, which might, without undue hardship, be insisted upon, (*a*) All woods purchased and felled by Government at the present high rates should be at once replanted by the owner as a condition of contract; (*b*) the Home Timber Committee should keep a careful record of the amounts of material cut from the areas they purchase, its nature, locality in which grown, etc., for this will prove a valuable record in future planting operations.

But neither the present imports nor the fellings in our own woods will bring down prices. That supplies are being obtained is satisfactory at the present moment, for we are at war. The material is urgently needed, and must be obtained from somewhere, no matter what the price that has to be paid. But are we going to continue indefinitely paying these exorbitant rates? And we cannot even depend on obtaining all we require—witness the recent action of Sweden in prohibiting imports of wood pulp, and our own Government's enforced action in this respect. Its effect on the press at once demonstrated our entire dependence upon imports. It is doubtful if the termination of the war will witness any great diminution of the timber demands. Rather an increase is to be expected. To add to the Allies' gigantic war bill by a subsequent outlay for timber for rebuilding purposes at double or treble its pre-war rates will be a suicidal and unstatesman-like result of a *laisser aller* policy. One has heard it said in reference to this and other kindred economic questions, "Oh! war time is not the time to consider such matters." I venture to think, in view of the demand which must ensue with the advent of peace, that this question is pre-eminently one which must be settled now; for the termination of the war will be too late. We had not the foresight to grasp what would happen at the outbreak of this colossal war. Let it not be said of us that its termination found us in the same state of unpreparedness.

My proposition is that the Allies should place themselves in a position to control the European timber market at the end of the war—to exercise, in fact, a State control over prices for a time, as the only effective means to cope with the enormous demand which will exist, and to prevent the formation of timber "rings," either by the Central Powers or others. It is no plea that such a thing has never been done before. The end of the war will find us, the war itself is finding us, doing a good deal we never thought to have to do.

First, then, we want to place our finger on accessible supplies in large quantities and owned by the Allies; and, secondly, to come to an agreement by which these supplies can be made available at the earliest possible moment with the object of bringing down the present preposterous rates.

If we examine the forestry resources of the Allies, the one great fact which immediately becomes apparent is the gigantic area of the forests in Russia, the Land of Forests, as it has been termed. For some years past I have made some study of the forests of European Russia, and also those of Finland and Siberia, and have some papers in course of publication on this subject. It is a most unfortunate thing for this country that we have known so little of Russia in the past—of its enormous possibilities and potentialities, and its great value in many ways to this country. Germany discovered it. Russia is honeycombed with Germans and German enterprises, mostly conducted, not for the welfare of Russia or in the interests of Russia and her people, but for the furtherance of German empire objects, and of those alone. Even in the matter of forestry imports Germany was undermining our pre-

viously unquestioned supremacy in the Russian timber markets. Germany has vast forest resources in her own country, a considerable portion of which is afforested; and not only afforested, but with the woods managed on the highest commercial basis possible. And yet in recent years her imports from Russia have increased rapidly, the increase being greater in proportion than the increase to Great Britain. And she has been importing from elsewhere also. Why? Was it because she really required the materials, or is the reason to be found in the fact that she has been deliberately storing up her woods, undercutting in them, with a set purpose in view? Did her wonderful organisation for this world war, and her deliberate intention to make it as frightful as possible, foresee the enormous damage that would be done to towns and the enormous demand which would exist for timber at the close of the war? During the war we know that she has been cutting down the woods in the territory she has occupied, and either utilising the materials for trench construction or other purposes, or storing them up for the great demand she expects at the peace. We know how Belgium is suffering in this respect.

From Russia we imported 35 per cent. of our European timber supplies in 1913. In Russia the Allies have for the purpose here considered a source of supply which should fulfil the objects required. Russia in Europe has an area of 447,500,000 acres of forests; Finland, 62,800,000 acres; and Siberia and Turkestan, the gigantic total of 853,000,000. Now much of this area in Russia, Finland, and Western Siberia produces the very materials which will be required in such enormous quantities at the close of the war, and which we import in such large amounts. And vast tracts of these forests are unworked or but slightly worked. A few years back the Government estimated that the fellings in the forests of Russia in Europe were something under 50 per cent. of the possibility. For instance, in the forests in the north, which are difficult to work owing to defective communications, only ·7 cubic feet per acre were felled out of an estimated 7 cubic feet. Fellings have improved somewhat since, but are still below the possibility. In Finland, again, published figures for the State forests show that, whereas in 1908 the mean annual increment put on per acre was estimated at 21 cubic feet for the whole country, the total amount sold was only 3·4 cubic feet per acre. Further, it was calculated that there were over 121 million trees of approximately 10 in. diameter and over at chest height in the State forests, and probably a like total in the privately owned forests. The gigantic tract of the Siberian forests is only partially explored, but estimates framed for 1911 show that 1,800,750,000 cubic feet of timber were available for sale in the State forests which had been explored, of which only 10 per cent. were disposed of. Russia has, then, large areas of accessible forests, or forests which, by a not very heavy expenditure, can be made accessible. She also has a very large population. Under the methods in force for exploiting this forest wealth, there exist throughout the country over 2,000 saw-mills. The war will leave her, however, with very little capital. Firstly, money, and next to that organisation, are necessary to open out these resources. My suggestion is that Russia should be asked by the Allies—by the British Government, if necessary, since we are very deeply concerned in this matter, as, unlike our other Allies, we have no forest resources of our own at our backs—to institute fellings on a large scale in those of her forests which are adjacent to the most suitable ports. Every saw-mill in these regions should be set to work converting timber at high pressure and stacking it in suitable depôts for transport to the areas required at the earliest possible moment. A definite scheme for the freight vessels necessary should be drawn up, and the tonnage required be earmarked for the purpose for which it is to be employed. As soon as the ports, or any port, of supply become open, a part of this tonnage should be made available to start bringing the materials ready to the spots arranged upon. This question of freight vessels has been very much before the public latterly. In itself it has greatly enhanced timber prices. The maintenance of the present prices is no more to Russia's advantage than ours or any of the other Allies, since we all have to foot the bill. To undertake the above sketched scheme money will be required to finance the saw-mills, open up inaccessible areas, pay the sawyers, and so forth, and my suggestion is that the British Government advance the sum which will be required for the purpose; whatever the sum necessary, it would be a mere bubble in the enormous present expenditure, and the savings which would ultimately result would several times over recover the sum spent. It would be money well laid out.

All that is required is a practical working scheme. So far as my study of the question has led me, it appears that the one practical possibility is to be found in Russia, and Russia

alone. It appears to be inadvisable to depend on the possibility of obtaining the materials to any great extent from the forests of the Central Powers. We have to beat them first. No one doubts that we shall, but no one knows how long the war will be prolonged. We should face the position as it now is, and make arrangements which will depend for their fulfilment on the Allies alone and on their resources. I have only here attempted to outline a suggested scheme. Time will not permit me to do more.

I come now to a point which is supplementary to the one we have just considered. If afforestation is taken up in this country (I am coming to that) on the scale now so urgently needed, we shall have to wait about thirty-five to forty-five years to obtain pit props from the woods, and longer for large timber.

I would suggest that to tide over this long period we should lease for a period of years a large area, or several areas, of the Russian forests and work them ourselves, in order to ensure that this country obtains a proportion of what she requires in timber, etc., independent of extraneous imports and at a reasonable price. our posterity should never have to face a position similar to the one which has confronted the nation since the outbreak of war.

In my opening remarks I drew attention to the position in afforestation matters existing in the early days of the reign of Charles II. We are in infinitely better case to-day, as we no longer require to wait the long periods necessary for the growth of large oak timber. Thirty-five to forty years will grow pit-wood crops and paper-pulp wood; and double this period most of the other conifer wood we so largely use.

It is not proposed to burden this paper with a wealth of statistics. But it will be of interest to glance at the areas of land in Great Britain and Ireland, and the proportion of woodland and mountain and heath land to total area. Roughly speaking, over nine-tenths of our wood imports are of coniferous timber. Now coniferous trees are just the class of trees which we can grow, and grow successfully, on the better portions of our waste lands. Britain, once covered with forests, is now one of the most poorly wooded countries in the world. The land areas are, roughly, as follows:—

	Land Area.	Woodlands.	Mountain and Heath Land.	Percentage.	
				Woodland.	Waste Lands.
England	32,381,000	1,666,000	2,306,000	5·1	7·1
Scotland	19,069,000	879,000	9,375,000	4·5	48·1
Ireland.	19,323,000	303,000	3,780,000	1·5	18·5
Wales	4,748,000	182,000	1,251,000	3·8	26·2
Total	75,521,000	3,030,000	16,712,000	3·9	21·6

I would ask, can we hope to get what we want at a reasonable figure in the future in an open market during the next forty years? Is it likely?

We can no longer afford to pay fancy prices for our timber requirements, and certainly not if there is a way out. Such a way I venture to think lies in these enormous Russian forests, these unexploited Russian forests not one-tenth of which Russia herself is likely to possess the capital to exploit during this period. Their resources are enormous. Why, then, should not this country arrange for a lease of portions of them to help make a certainty of our supplies during the period our woods are attaining a cutting size?

(2) *Our duty to posterity.* I now turn to the question of what should be done to ensure that

The percentage of woodlands in Great Britain and Ireland is 4 only. The area of mountain and heath land runs to over 16½ million acres, and much of this at present brings in a very small annual return—roughly, save in exceptional circumstances, from 2*s.* 6*d.* per acre to a few pence per acre only. There is a good deal of the latter in Scotland.

I will commence by briefly indicating what we have been doing towards attempting to ameliorate the returns from this poor land.

During the past quarter of a century several Committees have been appointed to deal with the Forestry question. The result, so far as the actual planting of woods for commercial purposes is concerned, has been *nil.* In 1887 a Parliamentary Committee considered this question and made recommendations. Had these been given

effect to, and had planting on a considerable scale been undertaken as a result, we might now have had a series of woods from which we could have drawn a supply of pit timber for the mines. Well-grown woods of this age are being cut down for this purpose at the present moment. But we did nothing. Again in 1902-3 a Departmental Committee of the Board of Agriculture reported on the subject. Unfortunately, it did not advocate any large planting scheme, but made valuable recommendations on the subject of a more extended system of forestry education. Effect was given to these recommendations in different parts of the country, and the question has since received hearty support from the Development Commissioners. But no planting was done. In 1908 a Committee appointed by the Department of Agriculture in Ireland recommended a scheme of planting up 700,000 acres in that country. Purchases of land for this purpose by the State were commenced in Ireland, and the work has since received considerable support from the Development Commissioners, and what may be termed a State Forestry Department has come into existence in Ireland.

In 1906 the Royal Commission on Coast Erosion and Afforestation was appointed. The Committee examined numerous witnesses, including all the expert advice procurable, and issued its Report in 1909. This Report recommended the planting of 9,000,000 acres by the State, of which 6,000,000 were to be planted in Scotland and the balance in England, Wales, and Ireland. With the exception of Ireland nothing was done. No planting was undertaken in Great Britain.

In 1911 a Departmental Committee on Forestry in Scotland was appointed, and issued its Report in 1912. In addition to recommendations on the subject of forestry education and the acquisition of a demonstration forest area, the question of afforestation in Scotland was considered. Flying surveys of the country were advocated in order to ascertain the available planting areas, the establishment of a limited number of State trial forests, and the appointment of an Advisory Forest Officer. The last recommendation of the three has been given effect to. In 1912 a very practical Report was drawn up by Lord Lovat and Colonel Stirling of Keir, late President of the Royal Scottish Arboricultural Society, and was published under the auspices of that society. I allude to the Glen Mor Survey. This work practically drew up what the forester would term a plan of operations for the afforestation of 60,000 acres in Glen Mor, through which runs the Caledonian Canal. To those interested in this matter, and to the nation at large, I recommend a perusal of this interesting and valuable scheme.

The Development Commission was appointed in May, 1910. During the six years of its existence it has enthusiastically taken up the forestry question. Briefly, at the outbreak of the war, as a result of its work, the position was as follows:—In England the counties had been formed into natural groups and a forestry adviser, who was attached to a university or college, had been appointed to each group, the salaries of these officers being paid from a grant from the Commissioners' funds. In Scotland an advisory officer to the Board of Agriculture had been appointed, and advisory officers were being appointed in the west and east of the country. But the Commissioners had gone further than this. They recognised that if the large areas of waste land existing in this country eminently suitable for afforestation were to be planted up, it was no longer possible to expect private proprietors to be able to find the necessary money. In fact, they realised that the work had now become a national one. The problem was admittedly difficult, but after careful inquiry into the various conflicting interests they offered a solution on the following lines.

The owners of the greater bulk of the afforestable land, in blocks of size suitable to achieve the aims of commercial forestry, consisted of large city corporations, water trusts of the great cities and towns possessing large catchment areas, and large landed proprietors.

To such bodies and proprietors the Commissioners were prepared to provide money for afforesting suitable areas, on the understanding that the land should be reserved for afforestation on commercial principles for at least one complete rotation. No rent would be paid for the land, but the landowner would receive his fair share of the proceeds for the timber grown on the area. The Commissioners would advance the money required for the planting work. The landowner's share of the ultimate proceeds would be based on the proportion which the rental value of the land bears to the estimated capital expenditure required to produce the crop.

The proportion of the receipts to go to the owner of the land were to be a matter of negotiation and arrangement between the proprietor and the Development Commissioners at the start in each case. It would be based on the present rental value of the land, its character, and other circumstances affecting the finance of the scheme.

Owing to the necessarily great variation in these data, it was not possible to draw up any general terms of assistance. The only stipulations, or probably the chief ones, laid down for advances of this nature were that the land to be planted should be in a sufficiently large block (500 to 1,000 acres) to be commercially exploitable when the woods reached maturity, and that these latter, from the time of formation, should be skilfully managed in accordance with a previously drawn up working plan and regular inspection by the district forestry advisers. It was also laid down that the afforested areas should be available as demonstration areas for the use of students and others interested in forestry—a condition which has been readily accepted.

The sums advanced were to be on a maximum basis of £5 per acre, including the fencing of the plantations, the loan to carry an interest of 3 per cent.

Up to the outbreak of the war loans of this nature had been made or promised for the afforestation of their catchment areas to the following corporations and water trusts in England and Scotland:—

England.

Liverpool.—A large area on Lake Vyrnwy, in North Wales, is being afforested on the above conditions; Liverpool having led the way in this new departure, readily acquiescing to the condition that the area should be available as a demonstration area.

Manchester.—Has been afforesting her catchment areas at Thirlmere, etc., during the past twenty years out of funds provided by the Corporation.

Birmingham.—Has a magnificent unplanted area in Central Wales, and has been for some time considering the question of afforesting it.

Leeds.—Is also contemplating the advisability and advantage to be gained by afforesting the land of this nature it possesses.

Scotland.

Edinburgh.—The Edinburgh and District Water Trust have commenced the afforestation of 600 acres of their Talla catchment area, and are also afforesting areas round their smaller reservoirs. The members of the Edinburgh Water Trust, by their enlightened policy, thus led the way in this matter in Scotland.

Lanarkshire.—A scheme for afforesting part of an area of 5,000 acres on the Camps catchment area owned by the Lanarkshire County Council has recently been adopted by that enlightened body, and the planting work has been commenced.

Other places are also considering the matter, but for various local reasons have not yet started their schemes.

It will be seen, therefore, that a commencement of this important work had been made before the war broke out. More important still, perhaps, is the fact that a number of the business men of the country had shown by their accepting the offer of the Development Commissioners that they realised the great possibilities of afforestation in this country. And this realisation had come to them before the war. The aspect of the question has now entirely changed. As has been shown, the price of timber in the future will certainly be greater than in the past, and afforestation will prove a paying investment.

Ireland.

The land conditions in Ireland are different, and a State Forest Department is now in existence. Land has been purchased, and three large centres are now owned by the State, and are being planted out of funds from the Development Commissioners. These areas are in Central Wicklow, County Cork (Ballyhoura), and Queen's County (Slieve Bloom).

This was, broadly speaking, the position of affairs at the outbreak of war. Now it is not open to doubt that the war has intensified the urgency of the afforestation question in this country. However near to their former level we may be able to bring prices, the tendency of the future will be an inevitable increase. For years the possibility of a timber famine in Europe has been discussed by experts as the probable outcome of the utilisation of the accessible available supplies in different parts of the world. That prices would have risen in a comparatively few years even without the war was a certainty. The war leaves the question in no doubt. Consequently forestry—commercial forestry—will be an even more paying proposition in the future than would have been the case.

And I believe all experts are convinced that, far from postponing the matter for any further consideration, steps should be taken now to prepare schemes of sufficient magnitude to ensure both success and adequate supplies for posterity. As a nation we are ever more wideawake in times of stress and danger; and since peace failed to bring this question home to us, even with the numerous Committees and Royal

Commissions which have sat upon it, may we not hope that the stress of war and the price we are paying for our fathers' dilatoriness may rouse us to its great urgency?

It will be said that money will be harder to get; interest will be higher: 5 per cent. will be now asked instead of 3 per cent. Granted, but with a return of prosperity this percentage should drop, and may even reach 3 per cent. again before the completion of the work. And it must be remembered that the additional cost should be well repaid by the excess price of the wood, which will be, so far as can be foreseen, some 25 per cent. to 30 per cent. higher than in pre-war days, as the supplies we have depended upon for the last thirty to forty years become cut out. Further, the investment will be a sound one. For when the woods become ready for the axe our children and grandchildren can utilise the considerable sums which such an investment will give them to defray some of the enormous national debt with which the country will be saddled. If from no other point of view, the planting of our waste lands, at present bringing in from 1*d*. to 6*d*. per acre, will be a sound investment. Had our grandfathers sixty to seventy years ago planted up a proportion of the waste lands of these islands, we should have been saved a large sum of money and a great deal of anxiety during the past year and a half. Had our fathers planted thirty to forty years ago, the pit wood required for the mines would have been available in this country, and the great trouble to which mine-owners were put and the ruinous prices they are paying for their timber, and we are all paying for our coal, would not have existed. Paper pulp from areas of spruce woods, which many parts of our lands can grow to perfection, would also be available, and the press would not be faced with the position which the action of a neutral and a scarcity of tonnage has now placed them in. And we should not be so alarmed at the thought that our morning paper and "extra specials" are going to become a luxury which we may even have to forego.

We have also a further problem confronting us in the provision of work for partially incapacitated soldiers and sailors, and of employment for the numbers of young men who, leaving their former sedentary occupations, have gone out to fight for the country. On their return these young men are likely to look with distaste at their former work. They will ask for a more active life. If that life cannot be provided for them in this country they will emigrate. And yet, if a campaign to plant up our waste lands, the present position of which is economically a disgrace to the nation, and one very far removed from the thrift and conservation and rehabilitation of the national resources which is now being so strongly advocated—if, I submit, a campaign of sufficient magnitude is undertaken to plant up these derelict acres which could grow so much of what we want, we should be able to provide employment for these young men; as also for our partially incapacitated soldiers and sailors.

One of the reasons why the recommendations of the Coast Erosion Commission were not acted upon was said to be the impossibility of employing the townsman in planting work owing to his inability to stand the strain and exposure of working on the soil, and his ignorance of the use of the spade and pick. That this was a fallacy the war has proved. Modern warfare entails the constant use of both these implements. In fact, they are probably used as much as the rifle, if not more so. The men of the towns have stood their training in the use of these tools, and numbers of youngsters, having a thorough acquaintance with them, and also hardened to exposure, should be available for afforestation work. With these facts staring us in the face, will it not strike us that the crusade preached by Evelyn two and a half centuries ago, and the Spirit for Planting—as it was quaintly termed—which it aroused, should once again be raised throughout the country, and that the few who have preached it in and out of season during the last quarter of a century should now have the nation at their back? After all, it is a question for the country. There are 3,000,000 acres of so-called afforested land—of woodlands. And we have, say, 9,000,000 acres of afforestable land; put it at 7,000,000, or even 5,000,000. It will do to go on with. It has been stated by many who know what they are talking about, that this land, or much of it, will bring in more under trees than under any other form of cultivation; or, to put it in another way, that this land will prove a greater national asset under woods than managed in any other way. Why not, then, set to work and get it planted up? If for no other reason than the one of national economy, the matter must be regarded as one of urgency. We can no longer afford to leave any source of national wealth unexploited. We must all agree that it has become a duty—a national duty—to see that every acre of land in this country is made to bring in the best return possible in the interests

of the community as a whole. Well, there exists a considerable acreage of land which experts are agreed is not bringing in anything like an adequate return. This land can be made to grow produce which is in great demand in the country, and which, in the absence of home-grown supplies, necessitates large imports that have to be paid for, and are going to be more expensive in the future. The aspect of the forestry problem has entirely changed from its pre-war position. The prices of timber are not likely to fall to their former level. So long as prices were low there was a good deal to be said for those who were against afforestation in this country. They put forward arguments which had certain elements of soundness in them, *e.g.*, the contention that forestry would not return even the 2½ to 3 per cent. claimed for it. The Great War has swept away such doubts and arguments. Prices have gone up, and the nation is now assured of successful financial results from afforestation work. On all counts the planting of this land will be of immense advantage to us. It will save imports, employ labour, and help home industries. In the last connection it will do more than help. It will result in establishing new ones. For the maintenance of a considerable area of forest in a country leads to the establishment of subsidiary industries such as paper-pulp mills, saw-mills, bobbin mills, furniture manufactories, and so on. And these afford employment to a considerable head of population.

To come now to a practical suggestion. Of the 3,000,000 acres of existing woodlands, it is extremely probable that the woods of merely commercial value will have been cut by the end of the war. The considerable areas which have a value other than the purely commercial—*i.e.*, which serve for shelter to stock and crops; are intimately connected with the sporting value of estates; or are maintained for amenity purposes—will, and should be, left standing. They are, in the main, of small size, and would not come within the minimum of 500-acre blocks which commercial forestry requires if it is to prove successful. They are of no considerable importance for our present case. The young commercial woods which have not yet reached felling size, must, however, be also included here. The areas which will have been felled, together with the considerable tracts of useless scrub, may be taken at 1,500,000 acres. If we add to this area 5,000,000 acres of the poor-class waste lands which could be profitably planted, we obtain an area of 6,500,000 acres which, in the interests of national economy, should be planted up at once. Therefore the planting work resolves itself into:

(*a*) Replanting the areas felled over during the war and the areas at present occupied by worthless scrub (of which there are extensive tracts in Scotland), amounting to 1,500,000 acres.

(*b*) Planting up 5,000,000 acres of at present treeless land, selecting in each county the better areas, which will yield a good return from the capital laid out.

In view of our growing requirements in timber, it is unlikely that this area of 6,500,000 acres will, when it comes into bearing, supply us with more than two-thirds to three-fourths of our needs of the future. But if the woods are scientifically managed, such an area should place us in a position of safety in the case of a sudden national emergency.

On the subject of cost, if we take an all-round sum of £3 per acre for the felled-over area, etc., class, and £4 per acre for the waste lands, our planting cost would come to 4½ million and 20 million pounds respectively, or a total of 24½ million pounds sterling—about a week's war expenditure. If 200,000 acres were planted annually, the area would be planted in 32 years. A planting plan should be drawn up, county by county, under which the felled-over areas, scrub areas, and the most accessible of the waste lands would be selected, and the order of the planting be laid down so as to ensure a proper arrangement of the woods for felling purposes, etc.

On the subject of the labour, it should be possible to start the work on the grand scale at the end of the war, when a considerable amount of first-class labour should become available. Partially-incapacitated soldiers and sailors will also be available—in fact, are available already. The work could be commenced immediately, as a matter of fact, by employing expert planters from amongst our prisoners. Now that prisoners are being employed by Government in felling operations, there appears to be no reason why they should not be also used for planting. We could plant up thousands of acres by employing them.

All that appears to be wanted is a plan of campaign and a favourable hearing from Government. It is not demanded here that additional work should be piled upon already overworked and harassed officials. It cannot be the desire of anyone to add any extra burden to the heavy ones already being shouldered by the Government. Rather the reverse. But at the present time it becomes a duty of each one of us to do

all in our power in the interests of national economy and thrift. The termination of the war is an indefinite period. Meanwhile there are large areas of land in this country which can be better utilised in the national interest, given the inauguration of a suitable scheme. Trees take a long time to grow; even the shortest rotation for a tree crop is approximately half of the proverbial "three score and ten years." Therefore each year which elapses without a commencement being made in remedying the deplorable state of affairs is a waste of national resources which can easily be expressed in pounds, shillings, and pence. There are men in this country perfectly acquainted, by knowledge, training and experience, with such work who would be quite capable of organising a scheme of this nature, and of seeing that the nation got full return for the capital sum laid out.

Is it too much to expect that the country will realise the economic importance of getting these millions of derelict acres under a profitable crop, and insist on the job being put through?

And may we hope that the great Society which soon after its inauguration, as I implicitly believe, and as Evelyn put it, awoke in the country the Spirit for Planting, and thereby saved us from invasion in the days of Napoleon, and that this Society, who took up the cause a century later, will come to the nation's aid once again. With their powerful support we may hope to secure that area of home woods which present-day necessities demand, which a full utilisation of our national resources and the campaign for thrift in all departments of life equally demand, and which our posterity is likely to need so sorely.

THE CHAIRMAN (Mr. John Slater) said he was not very familiar with the subject of forestry, as it was only when the wood became converted into building materials that he had to deal with it. He had been convinced, however, by the author, of the great importance of the forestry question to the country, and he was quite sure that the Government would be exercising a wise prescience if they went thoroughly into the question of afforestation in this country, because he believed the author was quite right in the statement that it would be a long time before the price of timber came down. Quite apart from the immense amount of building that would have to be done after the war, there was the terrible destruction of the forests of Belgium, France, Poland, and other places by artillery, and against the lessened supply there would be a greater demand. It had been the practice of the Government for a long time to send Indian cadets for forestry training to Germany, on account of there being no facilities for that training in this country; but it was perfectly certain that it would be a long time before that practice was revived. Therefore, apart from the provision of timber, some means of instruction in forestry had to be made available. He had been through the forests of Thuringia, the Black Forest, and the forests of Sweden, and had been struck with their appearance as compared with the bleak hillsides of Derbyshire, Scotland, and other places in this country. He would conclude by proposing a hearty vote of thanks to the author for his interesting paper, and for the charming series of slides he had shown on the screen.

The motion was carried unanimously, and MR. STEBBING having briefly replied, the meeting closed.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

MARCH 22.—REV. P. H. DITCHFIELD, M.A., F.S.A., "The England of Shakespeare." HUBERT HALL, F.S.A. (Public Record Office), will preside.

MARCH 29.—R. W. SETON-WATSON, D.Litt., "Pan-German Aspirations in the Near East." SIR EDWIN PEARS will preside.

APRIL 5.—ARTHUR S. JENNINGS, "Painting by Dipping, Spraying, and other Mechanical Means."

MAY 3.—PROFESSOR W. B. BOTTOMLEY, M.A., F.C.S., F.L.S., "Bacterised Peat."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

APRIL 6.—PROFESSOR WYNDHAM R. DUNSTAN, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India." THE RIGHT HON. LORD ISLINGTON, G.C.M.G., will preside.

APRIL 27.—JAMES MACKENNA, M.A., I.C.S. (Deputy Commissioner, Myaungmya, Burma, and designated Agricultural Adviser to the Government of India), "Scientific Agriculture in India."

MAY 18.—SARDAR DALJIT SINGH, C.S.I., "The Sikhs."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

MARCH 28.—PERCY HURD, "Next Steps in Empire Partnership." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council of the Society, will preside.

APRIL 11.—SIR DANIEL MORRIS, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland." The Right Hon. SIR WILLIAM MACGREGOR, P.C., G.C.M.G., C.B., will preside.

Dates to be hereafter announced:—

SIR FRANCIS TAYLOR PIGGOTT, M.A., LL.M., Chief Justice of Hong-Kong, 1905–1912, "Contraband and Blockade."

JOHN COLLETT MOULDEN, A.R.S.M., M.Inst.M.M., "Zinc, its Production and Industrial Applications." (Peter Le Neve Foster Prize Essay.)

G. P. BAKER, "Hindu Hand-painted Calicoes of the Seventeenth and Eighteenth Centuries, and their Influence on the Tinctorial Arts of Europe."

FOTHERGILL LECTURES.

Monday afternoons, at 4.30 p.m.:—

EDWARD A. REEVES, F.R.A.S., F.R.G.S., Map Curator and Instructor in Surveying to the Royal Geographical Society, "Surveying, Past and Present." Three Lectures.

Syllabus.

LECTURE I.—MARCH 27.—*Historical Sketch.* Introductory remarks—First attempts at surveying—Early surveying instruments and methods—First attempts at measuring size of earth—How early charts and maps were made—Beginnings of astronomical observations for fixing positions—Improvements in instruments and methods introduced in fifteenth century—First triangulation—Survey basis of early British maps—Further improvements in instruments and methods.

LECTURE II.—APRIL 3.—*Present position of Surveying and Mapping of the World.* General account, illustrated by maps and diagrams showing (1) parts of the world topographically mapped from reliable surveys, (2) those less accurately mapped from surveys chiefly non-topographical, (3) parts only roughly mapped from route traverses, and (4) those still entirely unsurveyed—Facsimiles of MS. maps of well-known explorers—Specimens of different kinds of surveys from which the earth has been mapped, with general account of them—Part taken by the Royal Geographical Society in promoting exploration and surveying—Work of the future.

LECTURE III.—APRIL 10.—*Modern Instruments and Methods of Geographical Surveying.* Advance made in recent years—Difficulties of obtaining accurate measurements—Circumstances that determine character of survey—Theodolites—Base line apparatus—Triangulation, with recent examples—Traverses with theodolite and tacheometer or subtense instruments—Plane-table, its use in topographical mapping, and recent improvements—Determination of heights—Photographic surveying—Astronomical observations for fixing positions.

The lectures will be illustrated with lantern-slides.

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m.:—

J. ERSKINE-MURRAY, D.Sc., F.R.S.E., M.I.E.E., "Vibrations, Waves, and Resonance." Four Lectures.

May 1, 8, 15, 22.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 20...Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Rev. Prebendary H. E. Fox, "Inscriptions and Drawings from Roman Catacombs."

East India Association, Caxton Hall, Westminster, S.W., 4.15 p.m. Sir Guilford Molesworth, "The Common Origin of the Religions of India."

Geographical Society, Burlington-gardens, W., 8.30 p.m. Dr. W. Leaf, "The Military Geography of the Troad."

London Chamber of Commerce, Oxford-court, Cannon-street, E.C., 2.30 p.m. Mr. E. Crammond, "British and German War Finance."

TUESDAY, MARCH 21...Statistical Society, 9, Adelphi-terrace, W.C., 5.15 p.m. Sir George Paish, "War Finance."

Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Discussion on "Some Aspects of the Design and Use of Glassware in relation to Natural and Artificial Illumination."

Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. 1. Valedictory address by the President, Sir Boverton Redwood. 2. Dr. J. A. L. Henderson, "The Natural Gas Industry: its Progress and Importance."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. Keith, "Sea Power as a Factor in the Evolution of Modern Races." (Lecture II.)

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Sir George C. Buchanan, "The Rangoon River-Training Works."

Zoological Society, Regent's Park, N.W., 5.30 p.m. 1. Mr. J. T. Cunningham, Exhibition of skins illustrating results of Mendelian Cross in Fowls. 2. Mr. R. I. Pocock, Lantern-exhibition to show structure of the Alisphenoid Canal in some Civets and Hyænas. 3. Dr. T. Goodey, "Observations on the Cytology of Flagellates and Amœbæ obtained from old stored Soil." 4. Major R. Meinertzhagen, "Notes on the Sitatunga or Marsh-Antelope of the Sesse Islands."

Electrical Engineers, Institution of (Local Section), 17, Albert-square, Manchester, 7.30 p.m. Mr. N. W. Storer, "The Use of Continuous Current for Terminal and Trunk Line Electrification."

WEDNESDAY, MARCH 22...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Rev. P. H. Ditchfield, "The England of Shakespeare."

Geological Society, Burlington House, W., 8 p.m.

Literature, Royal Society of, 20, Hanover-square, W., 5 p.m. The Dean of Durham, "Bishop Warburton's Critical Notes on Neat's 'Puritans.'"

Garden Cities and Town Planning Association, Mansion House, E.C., 3 p.m (Annual Meeting.) Report on the proposed Establishment of Small Holdings Colonies for Discharged Sailors and Soldiers.

Japan Society, 20, Hanover-square, W., 8.30 p.m. 1. Mr. W. Crewdson, "Japanese Leather." 2. Mr. A. J. Koop, "The Use of Leather in Japanese Military Equipment."

THURSDAY, MARCH 23...Royal Institution, Albemarle-street, W., 3 p.m. Professor H. E. Armstrong, "Organic Chemistry in War—Organic Products used as Propulsive and Explosive Agents." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8 p.m. Mr. A. Stewart, "The Development and Application of the Telephone."

FRIDAY, MARCH 24...Royal Institution, Albemarle-street, W., 5.30 p.m. Professor W. M. Bayliss, "The Mechanism of Chemical Change in Living Organisms."

Engineers and Shipbuilders, North-East Coast Institution of, Newcastle-on-Tyne, 7.30 p.m.

University of London, at the London School of Economics and Political Science, Clare-market, W.C., 5 p.m. Mr. C. Turnor, "The Land and the Empire." (Lecture III.)

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

SATURDAY, MARCH 25...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Radiations from Atoms and Electrons." (Lecture III.)

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—March 17, 1916.

Journal of the Royal Society of Arts.

No. 3,305. VOL. LXIV.

FRIDAY, MARCH 24, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

NEXT WEEK.

MONDAY, MARCH 27th, 4.30 p.m. (Fothergill Lecture.) E. A. REEVES, F.R.A.S., F.R.G.S., Map Curator and Instructor in Surveying to the Royal Geographical Society, "Surveying: Past and Present." (Lecture I.)

TUESDAY, MARCH 28th, 4.30 p.m. (Colonial Section.) PERCY HURD, joint author of "The New Empire Partnership: Defence, Commerce, Policy," "Next Steps in Empire Partnership." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council of the Society, will preside.

WEDNESDAY, MARCH 29th, 4.30 p.m. (Ordinary Meeting.) R. W. SETON-WATSON, D.Litt., "Pan-German Aspirations in the Near East." SIR EDWIN PEARS will preside.

Further particulars of the Society's meetings will be found at the end of this number.

PROCEEDINGS OF THE SOCIETY.

FIFTEENTH ORDINARY MEETING.

Wednesday, March 22nd, 1916; HUBERT HALL, F.S.A. (Public Record Office), in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Deb, His Highness Raja S. Tribhuban (of Bamra), Bamra, Deogarh P.O., Sambalpur, India.

Major, John Grayling, Clevedon Lodge, West Park, Eltham, Kent.

The following candidates were balloted for and duly elected Fellows of the Society:—

Middleton, Austin R., Baltimore, Maryland, U.S.A.

Patel, J. M. Framjee, J.P., Cumballa Hill, Bombay, India.

Starr, William J., LL.B., Eau Claire, Wisconsin, U.S.A.

THE CHAIRMAN, in introducing the author, said it was scarcely necessary for him to say anything about Mr. Ditchfield, who was known to many as an antiquarian of very sound learning, and as an interesting writer, whose style was never dull.

The paper read was—

THE ENGLAND OF SHAKESPEARE.

By P. H. DITCHFIELD, M.A., F.S.A.

It is fitting that in this year of grace, 1916, 300 years after the soul of England's greatest national poet passed away from earth, his countrymen should again crown him with their wreaths of laurel and unite in honouring his memory. It is fitting that on the advent of St. George's Day, the day on which the poet died, the thoughts of the members of this learned Society should turn towards our hero poet. But for the din of war and the world-wide clash of arms, a greater and a grander commemoration would have been possible. Foreign nations would have sent their tributes of praise and respectful homage to the poet's greatness. In no other country besides our own is Shakespeare more honoured than in Germany. I have met socially, and at a lecture, the distinguished German scholar, Professor Brandl, who two years ago lectured before the British Academy at Burlington House. Shakespeare was his hero, his unsurpassed poet, genius, dramatist and *litterateur*. In their affection and appreciation of the poet, Germany and England were united by close ties which could never be severed. German scholars vied with our English professors in trying to solve the mysteries of his surpassing genius. The two nations were made akin by the influence exercised by the poet, an influence that would increase as the years passed on, and produce peace and harmony between the German nation and our own.

That prophecy has been fearfully falsified. We should like to hear an expression of the Professor's views at the present time. Probably he has joined the pleasant company of other German writers, who maintain that our poet has left his native shores and sought an asylum and an enduring home in the happy Fatherland. One of our greatest authorities on Shakespeare, Sir Sidney Lee, has well said: "We welcome the

homage which Germany pays Shakespeare. We treat that homage as a tribute, in whatever spirit rendered, to poetic genius and power which are essentially English. The German homage to Shakespeare is an involuntary confession. There are lessons which Shakespeare can teach that the German has yet to learn, and we can wish nothing better for them and for ourselves than that they should supply the defect at an early date."

In spite of the strictures of Victor Hugo,* and the criticisms of Georges Pellissier†—who contends that the poet, the *dieu du théâtre* as he appears to most of his countrymen, was a bad dramatist—Shakespeare, ever since the days of Louis XIV., has found a welcome in France, and Voltaire sang his praises and sounded the trumpet of his fame in every European country.

This year we cannot celebrate the tercentenary of the poet as we should like, but not a few men and women of England have, by a study of the great national poet's writings, been braced to endure hardness, and by reflecting upon the achievements of the past have been encouraged to face the future with a high courage and a determined step.

One feature of Shakespeare's writings is his intense and ardent patriotism, his love of the England he knew, which we shall try to describe this afternoon. He loved

. . . that white-fac'd shore
Whose foot spurns back the ocean's roaring tides
And coops from other lands her islanders,
Even till that England, hedg'd in with the main,
That water-walled bulwark, still secure
And confident from foreign purposes.‡

Again, in the same play ("King John"), he utters the proud defiance of England's foes—

This England never did, nor never shall,
Lie at the proud foot of a conqueror.

* * * * *

Come the three corners of the world in arms,
And we shall shock them: nought shall make us rue,
If England to itself do rest but true.§

I should like to remind you of other passages in the plays breathing forth a resolute spirit and an undaunted heart, which, after the lapse of 300 years, are still the characteristics of Englishmen, and which will carry us through this greatest crisis in our great country's story.

My task this afternoon, however, is to bring before you the England that Shakespeare knew, the kind of buildings and surroundings on which his eyes were accustomed to rest, whenever he wandered away from the great city of London in the company of players, or abode in tranquillity at Stratford-on-Avon. He was a great traveller along our country roads. Oxford he knew well, where he often stayed at the Crown and, it is said, admired Mistress Davenant, the innkeeper's wife. In 1593 he went to Bristol with Lord Hunsdon's company of actors, whence he wandered by the Severn River to Shrewsbury, and then by Stratford back to London. In 1603 he was at Coventry, and later on Leicestershire knew him, and Coventry and Marlborough, and the towns and villages through which he passed. He was a much-travelled person, journeying in his early days on foot, and in the time of his affluence on horseback. The days of coaching were not yet. I am going to tell you of the manor houses and the humble dwellings of the poor that studded the countryside when Shakespeare wrote his immortal plays, and of the village life which he knew so well, and which finds reflexion in his verse.

Every person is in some way influenced by his environment, even a poet who creates. He is dependent upon what he sees and hears, upon the age in which he lives, on the tone and temper of that age. To know the surroundings of a man is to come nearer to the man himself, to see things with his eyes, and almost to touch that untold life which throbs within and behind his works, like the inner brightness that seems ever glowing from beneath the surface of the purest marble.

I may only touch upon one or two features of this Shakespearean environment, the material things upon which his serene brown eyes rested, and perhaps hear some of the strains of rustic revelry and the quaintness of the folk-drama that find expression in the antics of Bottom.

Our first thoughts will go back to that first twenty years of his life spent in the heart of England, that middle shire so picturesque and richly storied, Warwickshire, and to that quaint old town of Stratford which was ever dear to the poet's heart. His writings show that his mind was imbued and his imagination stirred by the legends and traditions of his native shire, by wandering amidst the woodland haunts of the Forest of Arden, by the beauty, variety and freedom of sylvan life. The deer ran wild in the thickets of Arden, and the plays show how skilled he was in the whole art of venery and how familiar with that "highest franchise of noble and princely pleasure." "Come, shall we go and kill us venison?" says the banished duke in "As You Like It"; and the latest

§ *Ibid.* Act V. Scene 7.

authorities agree in thinking that the traditional story of the poaching affray in Charlecote Park is founded upon fact, and that Sir Thomas Lucy of Charlecote was the prototype of Mr. Justice Shallow. By his rovings through the forest his mind was stored with the lore of park, warren and chase, and the loveliness of country sights and sounds.

His imagination was also fired by the stirring events in the history of his country. Eight miles away stood the lordly castle of Warwick, with all the associations of the great King-maker. The battle of Bosworth Field was fought only eighty years before the poet's birth, and we know how long stories and traditions linger on in the country. Even now in North Oxfordshire the peasants can tell you stories of the Great Civil War, just as if Charles and Cromwell were fighting the other day; so the men whom Shakespeare knew, the farmers and foresters of Arden, would discourse to him of the century-old battle; and if I mistake not his mother, Mary Arden, who was a lady of high degree, laid in his mind the foundation of those historical romances upon which that great series of historical dramas was constructed. To the value of these merely as a study of English history the great writer, Mr. James Gardner, bears abundant witness.

We will visit first the poet's home, the town of Stratford. We must not expect to find in this modern place all that Shakespeare knew and saw. Mr. Halliwell-Phillips, the great Shakespearean scholar, says that with the exception of a few diffused buildings, scarcely one of which is in its original condition, there is no resemblance between the present town and the Shakespearean borough. But some certainly remain. There is the well-known birthplace of the poet. It is one of the two houses in Henley Street purchased by John Shakespeare, his father, in 1575. The whole town in the sixteenth century consisted of these half-timbered, gabled-roofed, wood-and-plaster houses, with gardens at the back and also at the sides; the streets were broad, and took the form of a central cross, and at the intersection stood the High Cross, a solid stone building with steps below and open arches above. There were held the markets. The old bridge built by Sir Hugh Clopton still spans the Avon, and there was another cross in the Rother market, where quantities of cattle were sold—"Rother" being an old Saxon name for horned cattle, and Shakespeare uses it in his play, "Timon of Athens." Then we notice the grand old Gothic buildings that belonged to the Guild of the Holy Cross, consisting of a chapel, hall, grammar school and the almshouses of the ancient guild. This guild was dissolved at the time of the Reformation, but Edward VI. was induced to disgorge some of the spoil and refounded this and other grammar schools. Here the poet received his early education, being thoroughly grounded in Latin; and Sir Sidney Lee has shown by references to the plays how well he knew Ovid, though his scholarly friend, Ben Jonson, declared that he had "small Latin and less Greek." A visit to the large schoolroom makes one picture in imagination the clever, bright, brown-eyed boy sitting at his desk, poring over the "Metamorphoses," Lily's grammar, or writing in the "Old English" script. Across the road stood New Place, the large house purchased by the poet in the days of his affluence in 1597. It was pulled down by Sir John Clopton in 1702, and a fine new house built which was destroyed by Sir Francis Gastrell half a century later. Its site and the garden were purchased in 1876 through the exertions of Mr. Halliwell-Phillips, and placed in the hands of the trustees of the birthplace.

And then there is the stately church, which is much the same as it was in the poet's time. It is partly decorated and partly perpendicular, cruciform, with a handsome tower and octagonal spire, dedicated to the Holy Trinity. John de Stratford in 1332 founded here a chantry, and in 1351 Ralph de Stratford built "a house of square stone" as a college for priests serving the chantry, and the church became a collegiate church. Dean Balshall, in 1465–91, built the noble spacious choir, and in the time of Henry VII. the north and south transepts were added. Opposite the tomb and mural monument we can pay respectful homage to the poet's memory and gaze at his effigy, which the best authorities consider to be an authentic likeness of Shakespeare himself. It was erected by Dr. Hall, who married the poet's daughter, Susannah, and the likeness was taken from a cast. The artist was Gerard Johnson, "tomb-maker," who had a yard near the Globe Theatre. It was originally painted to resemble life, repaired in 1748, painted white in 1793, and repainted in 1861. There has lately been a lengthy correspondence on the subject in the Literary Supplement of the *Times*.

Shakespeare's age was an age of building. He must often have witnessed the masons and carpenters at work. It was an age when so many of our noble English mansions were being erected, an age that gave birth to Hatfield, Longleat, Audley End, Chatsworth, Hardwick,

and many other of the grandest English seats. It was an age of great architects: of John Thorpe (whose designs you may still study preserved in the Soane Museum, or better still in some of his masterpieces), of Bernard Adams, Bradshaw and Huntingdon Smithson. You will remember the poet's words—

> When we mean to build,
> We first survey the plot, then draw the model,
> And when we see the figure of the house,
> Then must we rate the cost of the erection,
> Which if we find outweighs ability
> What do we then, we draw anew the model
> In fewer offices, or, at least, desist
> To build at all.

All the country squires, the newly-enriched city merchants, or the *nouveaux riches* who had enriched themselves with the spoils of the monasteries, or been blown by lucky gales into the sunshine of Court favour—all these were building: some great palaces such as Wollaton, or Burghley House, or Longleat, others those charming manor houses that stud the countryside, set in a framework of dark trees in sequestered villages and obscure hamlets. Such a house is South Wraxall Manor House, erected originally by Robert Long about 1440. The present great hall, porch, kitchens and withdrawing room date from that period; but Sir Thomas Long followed the fashion of his age in the sixteenth century, and set to work to build the gateway with oriel and porter's lodge, and in Elizabethan and Early Jacobean times many alterations were made. You will admire these entrance gates with the view of the house beyond.

The builders of these houses were animated by the same spirit which moved Sir William Temple, cultured diplomatist, philosopher and garden lover, to write: "The greatest advantages men have by riches are, to give, to build, to plant and make pleasant scenes." And certainly they showed by their buildings that they were men of taste and refinement, very different from Macaulay's unflattering picture of the old English country squire, who is represented as an ignorant boor. It is not in the greatest mansions, the vast piles erected by the great nobles of the Court, enriched by the plunder of the monasteries, that we find such artistic perfections, but most often in the smaller manor houses of the knights and squires. These are the buildings which delight us, the charms of which we are attempting to set forth. The great noblemen and courtiers were filled with the desire for extravagant display, and erected such clumsy piles as Wollaton and Burghley House, importing Flemish and German artisans to load them with bastard Italian Renaissance detail. Nothing could be worse than some of these vast structures, with their distorted gables, their chaotic proportions and their crazy interpretation of classic orders. Contrast these vast piles with the typical Tudor manor house, the means of the builders of which, or their good taste, would not permit of such a profusion of these architectural luxuries, and you will discover the far greater attractiveness of the humbler dwelling. It is unequalled in its combination of stateliness with homeliness, in its expression of the manner of life of the men who built it.

These men built not only for themselves but for their sons and grandsons. They lighted what Ruskin calls the Sixth Lamp of Architecture, the Lamp of Memory, and considered it an evil sign of a people for houses to be built to last for one generation only. They felt that "having spent their lives happily and honourably, they would be grieved, at the close of them, to think that the plan of their earthly abode, which had seen, and seemed almost to sympathise in all their honour, their gladness or their suffering—that this, with all the record it bare of them, and all of material things that they had loved and ruled over, and set the stamp of themselves upon—was to be swept away, as soon as there was room made for them in the grave; that no respect was to be shown to it, no affection felt for it, no good to be drawn from it by their children; that though there was a monument in the church, there was no warm monument in the hearth and house to them; that all that they had ever treasured was despised, and the places that had sheltered and comforted them were dragged down to the dust. I say that a good man would fear this; and that, far more, a good son, a noble descendant, would fear doing this to his father's house . . . When men do not love their hearths, nor reverence their thresholds, it is a sign that they have dishonoured both . . . Our God is a household God as well as a heavenly one; He has an altar in every man's dwelling; let men look to it when they rend it lightly and pour out its ashes."

Such feelings seem to have animated the builders of the gems of domestic architecture that adorn our countryside. They stamped their impress on the homes they reared. They expected their children to respect their gift to their families. They carved their names or their initials or their arms over their doorways. They adorned them with texts or homely verse, pious thoughts, or quaint or humorous conceits. They built surely and well so that their houses might last, not for their own pleasure nor for their

own use, but for their descendants, who would thus venerate the hand that laid those stones and respect the memory of their forefathers and the honour of their house.

The view on the screen is Grimshall Hall, in the favoured shire of Warwick, which, perhaps, Shakespeare saw being built. It must have been just about his time. It is a delightful timber and plaster house with projecting porch, shallow bay windows supported by brackets, and brick clustered chimneys. You will doubtless, be acquainted with the usual plan of a manor house of this period, called Tudor or Elizabethan—the kind of house in which the poet lived in the days of his affluence. He seems to have liked a manor. He even joked about it. Costard and Biron are speaking in "Love's Labour's Lost." Costard says—

> The matter is to me, sir, as concerning Jacquenetta. The manner of it is, I was taken with the manner.
>
> BIRON: In what manner?
>
> COSTARD: In manner and form following, sir. . . . I was seen with her in the manor house, sitting with her upon the form, and taken following her into the park; which, put together, is, in manner and form following . . .

—and so on with his jesting, which, perhaps, seems a little forced to the admirers of modern humour and Mr. Bernard Shaw.

They were usually E-shaped, a pleasing but altogether fictitious fancy associating them with the name of Queen Elizabeth. That porch has a story to tell.

The old English squire loved to dispense hospitality and to give warm welcome to his friends. The door was a symbol of hospitality. There he welcomed their arrival; there he speeded his departing guests. He loved to make the entrance to his house fair and pleasant to the eye. From the steps he greeted his tenantry when they came to congratulate him on some happy event in his domestic life, or to condole with him in his sorrows; and there in the proudest moment of his life he stood to present his young son on the youth's coming of age, happy that the old line had not died out and that his son would maintain the honour of the family and carry on its old traditions. The porch and doorway were associated with many happy comings and goings, and some sad ones, too. It held a place of honour in the old manor house. Originally it was quite small and insignificant, a simple covering to protect those who knocked for entrance. Over the door the squire placed his coat-of-arms with mantlings, crest, and supporters—

> Two of the first, like coats of heraldry, due but to one and crowned with our crest.—"Midsummer Night's Dream."

The porch was increased in size with a chamber over it, and it became an important feature of the Tudor house. Completing the plan of an E-shaped house you would notice the four-centred arch and the Tudor dripstone, which are characteristic of the style. Through the porch you entered the screens, and on the left saw two or more uncovered entrances to the hall, and on the right the buttery hatch. As Maria says to Sir Andrew Ague-Cheek—

> Bring your hand to the buttery-bar, and let it drink.

We pass on into the hall, which remained for a long period the traditional plan of manor-house building, until the Italian style doomed its suppression. This large room with a dais at one end was the principal chamber in the house, where the family dined at the high table, and the retainers and servants in the body of the hall on trestle tables. A fire burned in an open hearth or in a huge fireplace with dog-grate. You remember when Capulet cries out—

> A hall! a hall! give room and foot it, girls.
> More light, ye knaves; and turn the tables up,
> And quench the fire, the room is grown too hot.

Mention is also made in the same place of the great chamber, the Elizabethan gallery, which is a beautiful feature of a house of the period. The bay window of the hall always marks the dais end, and betrays the original plan of the house, even after the hall has been robbed of its dignity and cut up into rooms and passages. The wings show the increased desire for comfort in Elizabethan times and provided greater room for retirement and privacy. Lattice windows had come into use in the poet's time. You will remember that he speaks in "All's Well"—

> So my good window of lattice, fare thee well.

Ufton Court, in Berkshire, is a fine old manor house. The kitchen is older than Shakespeare's time, but the main portion was built by Elizabeth, widow of Sir John Mervyn, who married Richard Perkyns in 1568, and has endured subsequent restorations. When Shakespeare was a child this house was mainly built, and was subsequently the home of Arabella Fermon, the reigning beauty of Queen Anne's day, the heroine of Pope's "The Rape of the Lock." The Perkyns were recusants, and there are two ingenious priests' hiding-holes. You would find

the hall with its minstrels' gallery, a fine room with stucco ceiling and pendants, black-and-white marble floor (1570), wherein Lady Mervyn's charitable gifts of bread, flannel, and calico are still distributed every Mid-Lent Sunday.

Ockwells (Berks) is another very interesting house, built by Sir John Norris in 1466, the heraldic glass being particularly important, showing the arms of the patrons, friends, and connections of the owner. Here is another view of the house as it was in Stuart or Elizabethan times, with a goodly company of guests issuing from its hospitable doors.

In any account of the buildings, whether manor houses, churches, or cottages, geology must play its part. I venture to exhibit a map of England showing the places where good building-stone was plentiful, where wood and forests yielded materials for the beautiful half-timber houses, where chalk and flint were found. Warwickshire had excellent building-stone and also good timber. I have already shown views of the early home of the poet, the school he attended, and other homes at Stratford which were of the good half-timber construction, with their projecting upper storeys and tiled roofs. The nearness of the upright timbers together is a sign of their construction, early in the sixteenth century. Later on we find, when timber was getting scarcer, that the timbers were placed farther apart, and curved braces came into fashion. Here are some examples of manor houses of this mode of building.

Cheshire is very celebrated for its "magpies." This word is given in Shakespeare, I think—perhaps some Shakespearean scholar will correct me if I am wrong—as "magot pies"—

> Augurs and understood relations, have by magot pies, and choughs and rooks, brought forth the secret'st man of blood

occurs in "Macbeth." These Cheshire magpies are not birds, but houses that take their name from the black-and-white plumage of the bird of omen.

Here is Prestbury, Cheshire; and here is Handford Hall, a delightful magpie, rich in beauty and romance. The Handfords of Handford were a sturdy race, like many of the other old families of Cheshire—

> Strong in the arm
> And weak in head.

One fought in the Crusades and took for his cognisance a wondrous star that fell from heaven before the armies of Saladin. Another fought in France against Jeanne d'Arc, and the last of the heirs-male fell fighting against the Scots at Cheviot Moor. He left a daughter, Margaret, who married first Sir John Stanley, the warrior sung by Sir Walter Scott, who quarrelled with the Leghs and became a monk, and, secondly, Uryan Brereton, who built the present hall surely and well, and the grand old staircase and panelling bear witness to his skill and a hiding-hole in the stairs to his ingenuity.

I do not know whether Shakespeare ever journeyed northwards and saw the Yorkshireman's rugged dwelling. He certainly was at York during one of his players' pilgrimages, and may have seen the lonely Cartledge Hall, far from the haunts of men, a manor house of the late fifteenth or early sixteenth century. Few people know of the existence of this. It is built throughout of large blocks of stone, and has the typical large stone slabs common to the district. It stands solitary and alone, exposed to the fierce storms that sweep over a wild, bleak, and rugged moor, challenging the fury of the tempestuous gales.

There is not much to tell of the history of these houses. They have passed through the ages peacefully and pleasantly. History fails to record any great events that happened in these ancestral halls or disturbed their placid existence. Plots and conspiracies could not be bred in such quiet homes, and if an occasional secret hiding-place tells of dangers feared or actually realised the page of history is silent. They resemble closely their owners, sturdy country squires who hunted and sported, farmed and tried to do their duty to their neighbours, and then slept in the neighbouring churchyard where a simple stone slab records their names and memories.

Not entirely without history, however, is the hall of Eyam. It is connected with the theatre, as the plague was conveyed to the village in some stage dresses that were sent there from London for the purpose of a masquerade.

Shakespeare was more familiar with brick-built dwellings, and I will show you a grand example, once the residence of another poet, George Crabbe, who loved Sarah Elmy, niece of John Tovell, farmer, who lived then at Parham Old Hall, the home of the Willoughbys, a very perfect example of brick building, and certainly one of the most picturesque. It was never a very great house, and is now a somewhat decayed farmhouse. It rises sheer out of its broad tree-girt moat, its walls of rich red where the bricks are crumbling, of green and grey and yellow where

they are overspread with moss and lichens. It was built by Sir Christopher de Parham, father of the first Lord Willoughby de Parham, between the years 1498 and 1527. The house has shrunk somewhat since then, and has lost some of its ancient features. It is a pity that no friendly hand can be outstretched to restore it to its former greatness.

Other brick houses I may mention are Wickenbeaux, Kent, the crowsteps of which are a sign of Flemish work. Flemish influence greatly increased in Shakespeare's day. Three years before his birth the immigration began from Flanders, the Flemings bringing with them their looms and the secrets of their trade of cloth-making. Colonies of Flemings settled in various parts of the country, chiefly in Kent, Surrey and East Anglia, where their fellow-countrymen were already established, and wherever they settled they left evidence of their presence in their buildings, their curved gables, crowsteps and other peculiarities. Preston-on-Stour has some remarkable clipped yews, which recall the line—

> Slips of yew silvered in the moon's eclipse,

and I exhibit a view of Ickham, Kent.

When we try to realise the aspect of the country as it was in the poet's time, we must remember that not only was his era an age of great building operations, but that England was then a land of ruins. Scattered over the country were the ruins of the great abbeys, priories, nunneries and other monastic buildings. When Shakespeare was a young man scarcely fifty years had elapsed since these magnificent piles had been shorn of their glory, some converted into dwelling-houses for the rich men who had profited by their dissolution, others with lead torn from their roofs, faced stone stripped from the thin walls, pictures of desolation and of the merciless fury of the iconoclast.

> The ruin speaks, that sometime it was a worthy
> building.

Here is a view of Netley Abbey, picturesque in its decay. The ruin was not so complete in the poet's day. Time's rude hand has further left its mark on the deserted sanctuary, and the greed of men through the centuries has pillaged its stones; and houses, bridges and churches have been reared from monastic ruins. One abbey of Reading, one of the grandest in England, sent its stones to renovate and build parts of Windsor Castle.

Perhaps he had in his eye a picture of a ruined house when he made Valerian say in "Two Gentlemen of Verona"—

> O thou, that dost inhabit in my breast,
> Leave not the mansion so long tenantless,
> Lest, growing ruinous, the building fall,
> And leave no memory of what it was.

Other ruins there were too. Bolingbroke bids us—

> Go to the rude ribs of that ancient castle;
> Through brazen trumpet send the breath of parle
> Into his ruin'd ears.

That was Flint Castle, where the second Richard lay. All over the countryside were such relics of feudalism with their embattled walls and high towering keeps. Berkeley Castle was standing then, as now, and is often referred to in the play "Richard II."—

> There stands the castle by yon tuft of trees,
> Mann'd with 300 men.

Kenilworth Castle was then in its prime, and readers of Sir Walter Scott will remember the amusing pageants that took place there on the occasion of the visit of Queen Elizabeth. Sudeley Castle also saw a similar pageant and masque, and still exists to tell us of the past. You will remember the touching scene at Kimbolton Castle in "Henry VIII.," and the vision of the injured Queen Katherine. Scenes are laid at Pomfret, Baynard's Castle, Middleham (Yorks). Very many have been destroyed since then. In the contest between King and Parliament, which burst forth in less than thirty years after the poet's death, many entered upon their last life-struggle. They were principally owned by Royalist gentlemen, who strengthened their defences and held them for their king. They endured long sieges and were thorns in Cromwell's side. When he triumphed, lest these strongholds of the malignants should again trouble him, he ordered them to be "slighted," their fortifications levelled with the ground, and their power crushed. Here is a view of a very gallant little castle, Donnington, of the Edwardian type, oblong in plan, with four curtain walls and towers at each corner. This is associated with another poet, with Chaucer, the father of English song, as it was held by Thomas Chaucer, who is, I believe, usually deemed to have been his son. It underwent a very gallant siege during the Civil War, and was held by a brave soldier, Colonel Boys, who maintained it during the whole war. Cromwell brought against it the full force of his battalions. It endured siege after siege, but never yielded until the king's cause was hopeless. Having been ordered to abandon Donnington, Colonel Boys

and his gallant men marched out with their arms, their flags flying and drums beating, having earned the respect of both friend and foe.

In the bailey court of these castles, then many of them little the worse for wear, and in the quadrangles of the mansions, were held brilliant pageants; at the embayed window the gay rhymer wrote his pastoral, or the daintily-ruffed lady read her Plato; on the terrace the moonbeams slept as gaily-dressed courtier and romantic maiden whispered their vows; in the dining-hall, with its timber roof, its rows of armour, swords and battle-axes, dark with blood-stains, the old soldier told his stories of wars in Ireland, the Netherlands or the Welsh marches; by the massive fireplace in the ladies' room, with its piled logs and brass furniture, the ancient dowager sat in winter, whilst the wind lifted the tapestries and hurried up the chimney like a moaning, muttering spirit; in the park there was room for hawking and hunting, for tilts, and even for duels. I should like to tell you of the furniture and contents of these houses, but my remarks must be brief. Many were enriched with the spoils of the monasteries. Froude has a fine passage on that subject. Shakespeare speaks occasionally of tapestry, though some of it was "worm-eaten," in "Much Ado About Nothing." Some he tells us was imported from Turkey, and Gremio was proud of his Tyrian tapestry, as well as of his cypress chests, his arras counterpoints, his fine linen, Turkish cushions bossed with pearl, his Venetian valence, his pewter and brass vessels which had taken the place of wooden platters. The heavy four-posted beds, in which, of course, Queen Elizabeth is sure to have slept, and tables and chairs of the period are not uncommon, and can still be seen in many old houses or collections of old furniture. Parts of the quadrangle, when there was only one, and the whole of a separate one when there were two, were taken up with kitchens, pantries, and store-houses. And then there was the garden, sometimes of many acres—a world of shady avenues, of espaliers, of clipped yews, of smooth lawns, of brilliant aviaries, of classic figures, of snug summer-houses, of ponds for goldfish, of cool and splashing fountains. "God Almighty first planted a garden," said Lord Bacon, with pious fervour, and when Laneham had seen the glories of Kenilworth Castle, its fruits, flowers, birds, fishes and trees, he said that "it was not so good as Paradise, for want of the fair rivers, yet it was better a great deal by lack of so unhappy a tree."

The poet's eye must often have rejoiced in the old gardens that were attached to the houses that he saw, and the poet's tongue loved to sing of the fair flowers they contained. The flowers of Shakespeare have formed the subject of a well-written book, and the garden at Stratford containing all his flowers will be known to you. Many a scene in the plays occurs in a garden. You will remember Leonato's garden in "Much Ado About Nothing," especially as it was represented on the old Lyceum stage when Sir Henry Irving and Miss Ellen Terry played so charmingly Benedict and Beatrice. There is that Duke of York's garden at Langley in "Richard II.," where the gardener gives directions for binding up—

> . . . Yon dangling apricocks,
> Which, like unruly children, make their sire
> Stoop with oppression of their prodigal weight;

and where the poor young queen hears of the deposition of the king, and when she dropped a tear the faithful gardener resolves to—

> Set a bank of rue, sour herb of grace:
> Rue, even for ruth, here shortly shall be seen,
> In the remembrance of a weeping queen.

The formal garden was coming into vogue. The name of Bacon is hazardous in Shakespearean circles, but I may mention Bacon's essay on gardens as affording a description of the style then in vogue. The poet speaks in the above-mentioned play of "a curious knotted garden," and here is a view of the style of gardening that was coming into fashion, the formal garden which Capability Brown and his imitators, in their quest for Nature, so wilfully and absurdly wrecked.

This old walled garden at Groombridge would have pleased the poet's eye. Or this Italian style of Renaissance art, with its yew hedge and terrace steps and statues.

The garden at Boscobel based on its formal lines is attractive, a garden that was destined soon after the poet's days to welcome its royal guest during those strange wanderings after the fatal fight at Worcester until the bark at Shoreham conveyed the youthful Prince to the shores of France.

Shakespeare sings sweetly of many flowers—of lilies, of carnations and streak'd gilliflowers, the fairest flowers of the season, that some call nature's bastards; of rosemary and rue, these keep seeming and savour all the winter long: of morning roses newly washed with dew; and here all old-fashioned flow'rets seem to grow—it is the garden of the Deanery at Rochester,

where lived that great garden-lover, Dean Hole.

But let us take leave of the country for a moment. As we pass from Warwickshire to London, or up and down the island, we meet with several towns and see them girt with strong walls, memorials of the gradual growth of the merchant cities, the progress of trade, and its triumphs over the powers of the barons and mediæval feudalism. Shakespeare often saw the walls of Coventry, now almost disappeared, whereon he placed Scene I., in "Henry VI., Part III."; of Warwick, too, where the town gates still stand to guard the main street. I can show you a few views of the strong walls of Southampton, which the poet saw, first reared in Norman times, and greatly strengthened in 1352 during the Hundred Years' War, after an attack of the French, which our Elizabethan Stow so graphically describes. You will remember how he tells of the captain of the pirates, the King of Sicily's son, who was beaten down by a rustic and cried "Rançon, Rançon"; but the rustic knew not the French tongue, and replied: "Yea, I know thee well enough; thou art a Françon, and therefore thou shalt die." So, unaccustomed to take gentlemen prisoners and to keep them for their ransom, he slew the knight. The discoveries of the new world by the gallant seamen of Shakespeare's day, and of the Cape route to the East Indies, deprived the town of its importance. Venice, that "held the gorgeous East in fee," no longer sent her merchant ships to Southampton Water. There was peace with France, and the town walls and castle became mere antiquarian relics, and were so when the poet lived. In the towns of England there was in his time much desolation. In the narrow, tortuous, unhealthy streets plague often stalked, and the people fled. Ruined priories and chantries were plentiful, and we gladly shake off the dust of the towns from our feet and go back to our country.

Here is a view of a picturesque yeoman's farmstead, such an one as Bishop Latimer described when he told of his father's home and household; and such an one as Richard Shakespeare lived in, with his son John, before the latter migrated to Stratford.

As Shakespeare journeyed from Stratford to London he would often gaze upon some village or market crosses as this one of Lambourn. There were two such crosses in his native town. No Puritanical iconoclastic zeal had as yet doomed so many of them to destruction; nor had the utilitarian spirit of the eighteenth and nineteenth centuries robbed England of its treasures. Stephano says of his mistress, Portia—

She doth stray about
By holy crosses, where she kneels and prays
For happy wedlock hours.

Here is another example, Shapwick Cross. These village crosses were for divers purposes. I have written about them elsewhere, and it would take too long to describe their uses. They were often placed in the churchyard, whither

Ghosts, wandering here and there, troop homeward,

as we read in the "Midsummer Night's Dream." And now, "I can see a church by daylight," says some one in "Much Ado About Nothing." The poet often gazed upon these holy shrines, set in every village, with their lofty spires or square tower standing amidst the tall elms, seeming to speak with a living voice proclaiming the stability of English life, the ever-enduring sameness passed on from year to year. There were nearly 10,000 churches in England in Shakespeare's time, and I hope he was, as I expect he was, a regular attendant at some of them. His memory is preserved in Southwark Cathedral, where a monument has been raised to his honour.

I may possibly be able to tell you something that may be new to you, unless you have been so incautious and foolish as to read one of my books which records the incident. I was visiting a friend in Buckinghamshire, at Grendon Underwood, and there I saw the porch where Shakespeare is said to have slept when he was wandering, a poor youth or strolling player, to London. He was disturbed by the village constable, who accused him of having robbed the church. The constable summoned some of the neighbours to help him to hold this terrible robber. The young poet prayed that he might be searched, and when no church goods were found upon him he exclaimed, "Much ado about nothing." The village constable is said to have been the original of Dogberry and Verges. The dialect of the characters in the play is said to be pure Buckinghamshire. Moreover, there is in the village a house known as Shakespeare's Farm, formerly an inn, called The Ship, where the poet is said to have often stayed. Indeed, you are shown the actual bank upon which "the wild thyme grows." All this I have tried to tell elsewhere, and will not trouble you now with any details.

And now we come to the village inn, which Shakespeare knew well, quite as well as the London inns and taverns which he used to frequent in company with the members of his

company of actors and the poets of his day. "Shall I not take mine ease in mine inn?" says Falstaff at the Boar's Head Tavern in Eastcheap. Along the great roads there were famous inns with accommodation for numerous guests, stabling for a hundred horses, and beautiful in their picturesqueness. The ordinary village inn was a hostel such as Izaak Walton loved to describe, "an honest alehouse where we shall find a cleanly room, lavender in the windows, and twenty ballads stuck about the wall, where the linen looks white and smells of lavender, and a hostess cleanly, handsome and civil." The great coaching days had not yet dawned. The "Mercury," the "Regulator" and the "Lightning" had not yet begun their adventurous careers. Not until 1667 did the "Flying Machine" run from London to Bath in three days (if God permit—as the pious poster announced). But travellers were numerous and inns plentiful, with their red-tiled roofs, the deep bay-window, the swinging sign-board, the huge horse-trough, the pump and outdoor settle; while within the old-fashioned fireplace with seats on each side in the ingle-nook, and the blazing log fire in the dog-grate, were cheering sights to the weary traveller. The sign-board that swings outside the inn has many stories to tell as it creaks in the wind. Some of these signs are remarkable for the exquisite ironwork that supports them, and tells of the skill of the village blacksmith of former days. The man who forged such beautiful specimens of ironwork had the heart and mind and hand of the true artist, though he was but a village smith. The signs, too, at least of the old ones, are well painted. A favourite Tudor sign was The Bull and Mouth, a corruption of Boulogne Mouth, or harbour, captured by Henry VIII. from the French. The Angel, at Grantham, The Bell, at Stilton, will occur to the minds of many students of old inns. Shakespeare would have met in his journeys a strange mixture of characters in these hostelries. The nobleman with a small army of retainers carrying half of his furniture with him as he moved from one of his seats to another; the knight of the shire, or the burgess of a town on his way to London to attend Parliament, spending his allowance of 2*s*. a day and expenses (members were paid something in those days, it appears—a practice which has now been revived); the poor scholar on his way to Oxford or the Temple, his cob and himself a compound of leanness and learning; a bishop and his chaplains, a highwayman, wounded soldiers, romancing sailors, musical tinkers and weary foot-passengers, paying a penny a night for their beds. Many scenes of this kind must Shakespeare have witnessed at Stratford, as the traffic stayed there between Oxford and Birmingham.

The view before you is called Ye Old Corner Cupboard, at Winchcombe, Gloucestershire, a fine inn of the smaller type, in the region of good building-stone, of Gothic design, the style of which lingered on in the West Country for some time after the mediæval period, and, indeed, is not yet dead.

Here is a view of another noted inn—The Bell, at Hurley—an old coaching inn of the fifteenth century on the road from London to Oxford. And we may just look (as we are here) at the Hurley Tithe Barn, a familiar object in Shakespeare's time. It belonged to the old Hurley Priory, which still stands with its neighbouring dovecotes.

It was within the yards of the great inns in country towns that plays were performed, the galleries running around the yard forming admirable places for watching the players. Few of these galleried inns remain, and several have disappeared from London within recent memory. In London the principal hostels used as primitive theatres were Bel Sauvage in Ludgate Hill; The Bell and the Crosskeys, in Gracechurch Street; The Bull, in Bishopsgate; and The Boar's Head, in Eastcheap.

The village shop in the poet's day, I expect, supplied the endless assortment of goods which still characterises our modern rustic emporiums, where you can get anything from a bootlace to a side of bacon. There is one at Lingfield, in Surrey, which has performed its useful mission since the fifteenth century. It has a central recess with braces to support the roof-plate. Formerly there was an open shop-front with wooden shutters hinged at the bottom of the sills, on the tops of the stall-boards, and which could be turned in the daytime at right angles with the front and used for displaying wares. In some cases there were two shutters, the lower hinged in the bottom sill, as I have described, while the upper was hinged to the top, and, when raised, formed a pent-house roof. Shakespeare alludes to this arrangement when he says, in "Love's Labour's Lost"—

> With your hat pent-house like o'er the shop of
> your eyes.

And now I must show you some examples of old cottages. There is a sad contrast between the unsightly modern cottages, with their

glaring brick walls, their slate roofs, their little ungainly stunted chimneys, and the old-fashioned thatched or tiled dwellings that form so charming a feature of English rural scenery, and must have delighted the poet's eye.

It is a small house of odd, irregular form with various harmonious colouring, the effects of weather, time, and accident, the whole environed with smiling verdure, having a contented, cheerful, inviting aspect, and a door open to receive a gossip neighbour or weary exhausted traveller. Such is a cottage which the poet and the painter loves, a type which is happily not extinct in modern England—

Its roof, with reeds and mosses covered o'er,
And honeysuckles climbing round the door,
While mantling vines along its walls are spread,
And clustering ivy decks the chimney head.

In the construction of timber-framed houses we noticed the use of wattle and daub for the filling up of the panels formed by the horizontal and vertical timbers. The builders of our old houses were not content to leave the surface plain and unadorned. The panels pleaded for decoration. In many cases the whole of the surface of the walls was plastered over, and this afforded a wide field for the plasterer's art, and he did not fail to make extensive use of it. His art was called pargeting or parge-work.

We give an interesting example of external parge-work in the house at Newport called the Crown House, which tradition says was inhabited by the fascinating Nell Gwynne, who died in 1687. The date 1692, which appears on the house, probably refers to its restoration and to the erection of the porch. The plaster-work is excellent, but it is being sadly worn by the severity of the English climate.

I have consumed so much of your time in describing the kind of houses that Shakespeare knew that I have left little for the recording of village life and character. We can see the old squire in his manor house, a very interesting person. You must not take as gospel truth all that Macaulay says about him. He was by no means the ignorant boor such as the historian, to his own disgrace, painted him. He was fairly learned and knew Latin, perhaps, better than the ordinary country gentleman of to-day. He had travelled abroad. He went to London once a year and purchased books. He discharged his duties as a magistrate with good common-sense, aided by a little law. His amusements were chiefly hunting and hawking. He was not troubled with that absurd gambling spirit which a century and a half later caused the ruin of so many of his class. One squire gambled away his house room by room, and when it was pulled down gambled away the bricks. Another lost his house and estate through gambling and hanged himself in an attic, and his ghost haunts the house in revenge, because his widow married the man who had won all his money. The Elizabethan squire was not so foolish. He liked a quiet game at bowls in the evenings on his well-kept green, and could appreciate poetry. I expect he looked down with scorn on the new fashion, which had just set in, of smoking tobacco—a dislike which probably the poet shared, as he never mentions it. His wife and daughters attended to the wants of the villagers, performed the usual household duties, did needlework, and played on the virginal. And cards and draughts, dice and dancing were indulged in—the old country dances, which are not really country dances, but *contré* dances, the partners standing opposite each other as in Sir Roger de Coverley. But we have not time to discuss Elizabethan dancing, or, perhaps, some of the ladies might kindly demonstrate how to dance the canary, or the brawl, or help us to realise Beatrice's description of the pavin.

I have no time to tell of rural sports, of cock-fighting, archery (which was going out of fashion), of church-ales, fairs, football, and much else.

Our Berkshire registers of this period tell of a terrible event at North Mouton during a football match in Shakespeare's time in 1598, and shows that the game was rough and fast and furious. The poet bears witness to the same fact. Lear says to the steward—

Do you bandy looks with me, you rascal? (*Strikes him.*)

STEWARD: I'll not be struck, my lord.

EARL OF KENT: Nor tripped, neither, you base football player (*tripping up his heels.*)

Tripping is not considered quite legitimate play in modern football.

This register records the burial of two men, Richard and John Gregorie, and states: "These two men were killed by ould Gunter. Gunter's sonnes and the Gregories fell together by ye yeares (ears) at football. Ould Gunter drew his dagger and broke both their heads, and they died both within a fortnight after." Sad to relate, old Gunter was the parson of the parish. Possibly he was witnessing the savage game. His sons and the Gregories were playing fiercely in the scrum. He saw his boys overthrown by their opponents and, fearing for their lives and carried away by excitement, drew his dagger, and struck the fatal blows. Strange to say, he was

not hanged, or deprived of his living, or even tried for manslaughter. But this is a curious revelation of the fierceness of Elizabethan football.

Parish registers, recording the short and simple annals of the poor, are full of interest. Here is a page from the Ruscombe register written twenty-six years after the poet's death. It is the only record of a skirmish fought near the village during the Civil War, wherein is mentioned the burial of several soldiers. Here is another page two years later.

Briefs are mentioned in Shakespeare, I believe they were a mode of collecting money for divers good purposes. If a fire destroyed a village or a storm damaged shipping, or other misfortunes occurred, a brief was issued by authority and collections made in churches throughout the land.

Here is a page of briefs of the seventeenth century. Amongst them is one for the redemption of captives taken by the Turks or Mediterranean pirates, who cruelly tortured their victims.

Here is a picture taken from a contemporary print of the kind of tortures inflicted upon their poor captives, from which the alms of the charitable were intended to rescue them.

In "Comedy of Errors" we read of—

> Tartar limbo worse than hell,

and in the "Merchant of Venice"—

> From stubborn Turks and Tartars never trained
> to offices of tender courtesy.

We, too, in England had some tortures for the unfortunate or the criminal. Punishments, like sports, in the poet's time, were cruel. You might have seen in London a poor baker dragged on a hurdle through the streets for making bad bread. In the country we had our stocks. Shakespeare often alludes to them. Falstaff complains—

> The knave constable had set me in the stocks.

In "All's Well" a victim is said to have been set in the stocks all night; and other passages are doubtless familiar to you.

In one play someone says, "Fetch hither the stocks," showing that portable stocks were sometimes used. These are at Odiham, Hants. Another view.

An accompaniment to the stocks was the whipping-post, which was in frequent use. There were many beggars and poor souls in Shakespeare's time, the result of the dissolution of the monasteries, who were the tramps of the day, and caused as much trouble as do the modern variety. But the authorities of those days had a summary method of procedure, and ordered the tramps to be whipped. Sometimes they consoled the sufferers (as at Hungerford) by giving them some money.

Ducking-stools and branks were much in vogue for scolding women, and here is a view of the latter terrible implement of torture which poor women had to endure who had dared to protest against the vagaries of drunken or faithless husbands, or to speak their minds to a local tyrant dressed in the apparel of a brief authority.

All these were going merrily in Shakespeare's time. The poet loved all the familiar scenes and joyous customs of the country, and doubtless took his part in them in his youthful days. You will remember the humours of the sheep-shearing festival in "The Winter's Tale." People are uncertain as to what period of our history may be assigned the epithet of "merry." Our Chairman, I know, takes rather a gloomy view of the Elizabethan time, but there seems to have been much gaiety in rural England. There were the festivals of Christmas and New Year, of Easter and Whitsuntide, the May Day revels, the pageants of Whitsuntide, the beating of bounds during Rogationtide; and Shakespeare would often go to Coventry and see there the famous pageants, processions, and plays, mysteries and moralities, while strolling companies of players used to roam the country, as Shakespeare himself did. He was probably first attracted to the stage by the playing of certain companies of actors at Stratford in his youth. Probably the Coventry players may have provided him with models for Bottom and his companions, as their playing was rather ridiculous, and caused the Queen to exclaim, "What fools ye Coventry folk are!"

Such were some of the characteristic features of Shakespeare's England. I have not touched upon the London of his day. That is too large a subject for this lecture, and would require a whole lecture or volume for a complete survey. Moreover, it has been well described by Mr. Ordish, in my two volumes of "Memorials of Old London," and by other writers. The trade and commerce of the period, the development of England's sea-power, which has ever held its sway from the time when England overthrew the Invincible Armada to the present day, and has proved itself the salvation of our country and the chief factor in our present world-wide war; the Court, the drama, and the literature of the time; the religious controversies and the contending factions of Protestant, Roman

Catholic, Puritan: all these I have been obliged to omit from this sketch of the England of Shakespeare.

I have tried to conduct you along the broad highway, the country roads of rural England, where traces are still left of the England Shakespeare knew, to linger at the village inn, the manor house and humble cottage, to see the rustics at their sports and merry-makings, and if I have lingered too long on special features and omitted others, the fault must be partly attributed to the limitations of an illustrated lecture and to the special predilections of the lecturer—a fault that I hope to amend when the book which I am now engaged upon sees the light.

As far as circumstances will allow during the coming celebrations of the poet's death we shall try to study anew the life, work, and character of our national bard; and if we would do that we must place him in his Elizabethan setting and cast our thoughts back three hundred years and more, to live in his time, and know the manners of his age. Students of his works, Shakesperean scholars, who can analyse each play and who revel in the perplexing meanings of divers words and passages, in his allusions and problems of language, in his sources of knowledge, and the origins of his plays, in divers readings in the classification or chronology of his works, and such-like questionings, may scorn the humbler task. But it is no less important. The jewel gleams in the sunlight, but its setting adds to its beauty.

Shakespeare sent forth a burning message for all time of ardent patriotism and love of England. It is not without signification that his death-day falls on the Feast of St. George, England's patron saint, whose name was the battle-cry of our warriors in many a bloody field. It was "the ancient word of courage, fair Saint George"* that inspired "our men with the spleen of fiery dragons."† May we, in this modern Armageddon, sound forth the same encouraging cry (slightly modified): "God and Saint George, England and victory."†

THE CHAIRMAN (Mr. Hubert Hall), in moving a vote of thanks to the author, said the paper was a most interesting and instructive one. There were many aspects of the subject and many methods of study, and it was clear that the author set out with the special object of placing before the audience the England of Shakespeare based on his great knowledge of archæology. The occasion —the approaching tercentenary of the death of the poet—was an appropriate one. There were a great many records in existence, most of them of native origin; but there were also sources of foreign origin, and he was rather surprised that two or three of these descriptions of Elizabethan England had been lost sight of in recent years. He had been very much struck by the shrewd observations of foreign travellers, particularly a German, Leopold von Wedel, of Stettin. This MS. was discovered by the British Consul at Stettin, who sent a transcript to England. The German traveller appeared to have seen everything at the Court of Elizabeth in 1554-55: he saw the Tower lions; a prize fight before the Lord Mayor and the City Fathers and the citizens, in which the combatants fought with a kind of cestus, and were described as brawny men, well trained. He saw Whitehall, Hampton Court, Sir Walter Raleigh, and Parliament, and recorded a speech by the Queen at the opening of a session. Von Wedel also went to Scotland and made some very interesting remarks about the Scottish nation. There were probably many other descriptions of England which would serve to check the accounts of writers like Harrison and others. Another source which might be explored was the household accounts and diaries, many of which must still be buried in country houses. He remembered the diary of Lady Hobey, an English gentlewoman of very wide knowledge of politics and great ability in conducting her husband's business, a diary which was transcribed by a lady of the Royal Historical Society. No doubt many such diaries had escaped the researches of the Historical Manuscripts Commission.

The motion was carried unanimously and the meeting then concluded.

* "Richard III.," Act V. Scene 3. † *Ibid.*

PARTITION AND CONSOLIDATION OF HOLDINGS IN THE PUNJAB.

Probably the greatest hindrance to the progress of agriculture which is ever encountered in any country is the holding of land in common as the joint property of a village or of a family. Sooner or later, in the Old World at least, in one country after another the problem of the partition of the land into individual holdings has to be faced. But a few years ago it was Russia which was forced to free the land from the hold of the village community. To-day they are struggling with the problem in India, where the village is perhaps more highly developed than it has ever been in any other country, but where, for good or evil, the British administrators have encouraged individual ownership.

In the October number of the *Monthly Bulletin of Economic and Social Intelligence*, Sir James Douie writes with the weight of authority upon the subject of the partition of communal land and the consolidation of scattered holdings in the Punjab.

The Punjab is in the main a country of small

peasant landowners organised in village communities. An ordinary holding in the plains covers from five to ten acres, but the fields composing it do not lie in a single block, but are scattered over a wide area. This happens as the result of a desire to treat each family or subdivision of the tribe to whom the whole area of land belongs with perfect fairness. The land comprised within the area being uneven in quality, it is sought to secure an equitable distribution of the whole by assigning to each family a certain proportion of each kind and quality of land. The disadvantages of such subdivision are obvious, and are sometimes felt so severely as to induce a village community, voluntarily and without official help, to undertake partition of the common land and even consolidation of holdings. When a village has carried out a scheme of partition, and all the necessary exchanges have been effected, particulars of the new holdings may be entered by the village registrar in the mutation register, and, after attestation by a revenue officer, embodied in the record of rights.

It is not often that a friendly settlement of partition transactions can be secured. Usually the proceedings are so complicated that it is considered advisable to invoke the help of a competent revenue officer. The Government in the Punjab has always discouraged the partition of whole villages, but where the shareholders in a joint holding apply to have their interests separated, the law is careful to provide that claims shall be decided by officers of sufficient rank and experience. In Sir James Douie's opinion there is no better test of the worth of a revenue officer than his capacity to deal competently with a complicated partition.

Where there is a real dispute as to title it is necessary to obtain a judicial decision before partition can be carried out. If existing titles are undisputed the right conduct of the proceedings depends mainly upon willingness to take pains. A man dealing with a partition must be prepared to ascertain the real position of the contending parties, to examine all objections brought forward, and where necessary to visit the village and ascertain for himself the truth as to the relative value of different parcels of land. Wherever possible a tenant is permitted to retain land which he has permanently improved, and this may often be made possible by giving to other shareholders a larger share of unimproved land.

The law relating to partition is contained in a chapter of the Punjab Land Revenue Act, but there is no legislation upon the subject of consolidation or "restripement." Necessity has driven the cultivators in some cases to find a remedy for dispersion by exchanging outlying parcels of land, and such arrangements tend to become more common as the system of irrigating land extends in the Punjab. Government now makes it a condition that rectification of field boundaries shall precede the introduction of canal water into a village. Unfortunately, existing orders do not encourage any attempt to add consolidation of holdings to rectification of boundaries. The Indian peasant is intensely conservative, and regards all reforms with suspicion and dislike. It is unwise, therefore, to press them upon him. However, he is quite alive to the advantage of occupying a field of regular shape which can be irrigated rather than one of irregular shape which cannot be irrigated, and he will, little by little, come to appreciate the advantage of having one holding of decent size rather than (as sometimes happens) twelve or even more scattered parcels, whose total area is less than a couple of acres.

MANUFACTURE OF RADIUM IN THE UNITED STATES.

According to an announcement made recently by Mr. Franklin K. Lane, the United States Secretary of the Interior, the production of radium from Colorado carnotite ores by the Bureau of Mines, in connection with the National Radium Institute, has passed the experimental stage in its new process, and is now on a successful manufacturing basis. He also declared that the statements made to Congress concerning the ability of the Bureau of Mines to produce radium at a greatly decreased cost as compared with other processes had actually been accomplished, and that the costs were even less than predicted. From information furnished by Dr. C. L. Parsons, who is in charge of the radium investigations of the Bureau, the cost of one gramme of radium metal produced in the form of bromide during March, April, and May of last year was 36,050 dollars (about £7,210). This includes the cost of ore, insurance, repairs, amortisation allowance for plant and equipment, cost of Bureau of Mines co-operation, and all expenses incident to the production of high-grade radium bromide. When it is considered that radium has been selling for 120,000 dollars (£24,000) and 160,000 dollars (£32,000) a gramme, it will be realised what the Bureau of Mines has accomplished along these lines.

The cost of producing radium in the small experimental plant during the first few months of the Bureau's activities was somewhat higher, but not enough seriously to affect the final average. It should not, however, be inferred that this low cost of production necessarily means an immediate drop in the selling price of radium. The National Radium Institute was fortunate in securing the right to mine ten claims of carnotite ores, and this was practically the only ore available at the time.

Since then new deposits have been opened; but these are closely held, and, according to the best judgment of the experts employed by the Bureau of Mines, the Colorado and Utah fields, which are much richer in radium-bearing ores than any others known, will supply ore for a few years only at the rate of production that obtained when the European War closed down the mines. The

demand for radium will also increase rapidly, for it is stated that the few surgeons who have a sufficient amount of this element to entitle them to speak from experience are obtaining encouraging results in the cure of cancer as their knowledge of its application improves.

The ten carnotite claims being operated at Long Park, Colorado, by the National Radium Institute have already produced over 796 tons of ore, averaging above 2 per cent. uranium oxide. The cost of ore delivered at the radium plant in Denver has averaged 81.30 dollars (about £16 15*s.*) per ton. This included 15 per cent. royalty, salary of Bureau of Mines employees, amortisation of camp and equipment, and all expenses incident to the mining, transportation, grinding, and sampling of the ore.

A concentrating plant for low-grade ores has been erected at the mines, and is successfully recovering material formerly wasted. Grinding and sampling machinery has been installed at Denver, and a radium-extraction plant erected in the same city. The radium plant has now a capacity of three tons a day, having been more than doubled in size during the last twelve months. At first the plant had been run more or less on an experimental scale, although regularly producing radium since June 1914. To July 1st, 1915, slightly over three grammes of radium metal had been obtained in the form of radium barium sulphate, containing over one milligramme of radium to the kilogramme of sulphates. The conversion of the sulphates into chlorides, and the purification of the radium therefrom is easily accomplished and with very small loss of material. Unfortunately, however, special acid-proof enamel ware, obtainable only in France, has not been delivered of sufficient capacity to deal with the crystallisation of the full-plant production, so that a little less than half the output, or, to be exact, 1,804 milligrammes of radium element, have been delivered to the two hospitals connected with the National Radium Institute. The radium remaining can be crystallised at any time from neutral solution in apparatus already installed; but the greater rapidity and efficiency of production of this very valuable material by the methods used have decided the Bureau of Mines to await the completion of apparatus now being built before pushing the chloride crystallisation to full capacity.

The average radium extraction of all ore mined by the National Radium Institute has been over 85 per cent. of the amount present in the ore as determined by actual measurement. The amount present in the ore has been found, in fact, to be essentially the same as the theoretical amount required by the uranium-radium ratio. The extraction figures for the last five car-loads of carnotite treated has shown a recovery of over 90 per cent. in each case.

A bulletin giving details of mining, concentration, and methods of extraction is being prepared by the Bureau of Mines.

ARTS AND CRAFTS.

British Industries at the Victoria and Albert Museum. — The Victoria and Albert Museum appeared in an entirely new light as the home of the British Industries Fair organised by the Board of Trade. The visitor, when he first emerged from the subway into what would ordinarily be the ironwork section, began to wonder where he could be. What under normal circumstances is a spacious corridor was turned into a narrow lane flanked on either side by wooden booths covered, as it seemed at first sight, with teddy bears; and the large courts which debouch from it, though the tapestries on the walls remained and could be seen towering high above the temporary partitions, were filled with stalls displaying stationery, printing, and fancy goods.

It is to be regretted that the authorities did not see their way to holding the exhibition elsewhere. The courts at South Kensington, though spacious enough, are not peculiarly well adapted to shows of this type, and the lack of adequate wall space entirely prevented the display of posters and other large work. Again, the Victoria and Albert Museum is indeed concerned mainly with industrial art and not with fine art, but it stands for art; whilst at the fair, although a certain amount of work of various kinds with some claim to artistic merit was included, the majority of the wares on view were frankly, not to say blatantly, "trady." That the Museum should have been utilised for an exhibition of modern British industrial art would have met with the approval of everyone; to turn it for the nonce into a show place for manufactured toys and nick-nacks of all kinds seems hardly fitting. The industries represented were not very numerous though they covered a good deal of ground. There was a large collection of toys, an almost equally imposing array of fancy goods, and a very fair quantity of printing and stationery, whilst one large court was given up to glass and pottery.

Printing and Stationery.—In the printing and stationery sections a good deal of satisfactory work was to be found, and it comprised not only excellent colour printing of various kinds, but also good examples of type-setting and letterpress printing. In this last division the work of the Oxford University Press stood out, not only for the excellence of the collotype versions of ancient manuscripts, etc., and for the setting-up of books in all sorts of out of the way characters, but also for the printing of more ordinary and simple work. Messrs. George Pulman and Sons, of Thayer Street, showed good reproductions in facsimile colours of Louis Raemaeker's cartoons (Raemaeker's method, of course, of using colour for emphasis, both lends itself to reproduction and makes monochrome renderings rather unsatisfactory), and also examples of tasteful letterpress printing. The Medici Society, of Grafton Street, sent some of their admirable prints in colour from the Old Masters, and a selection of books

published by the Riccardi Press. They were also showing coloured postcards of a number of well-known pictures. These are in an altogether different category from the ordinary German coloured postcards with which we are familiar. They are not highly-coloured daubs caricaturing the originals, on the other hand they err rather on the side of sombreness. They are good efforts in the right direction, but they are not wholly satisfactory. In some respects they are not as good as the earliest productions of a firm in Milan (whose name suggests a possible German origin), who attempted the task of making good coloured postcards from the frescoes and other paintings in the Brera and elsewhere. It is true that the later productions are not (or were not before the war) quite as successful as the earlier ones, but they were still far above the level of the ordinary German work. Their fault lay in a certain want of depth. Before we have an ideal coloured postcard we shall have to obtain a combination of the qualities of the English and Milanese cards. Perhaps when we had achieved it the price of the postcards would be quite prohibitive, and meanwhile the Medici cards are to be welcomed as a very great improvement on the ordinary work. It is to be hoped that after the war, visitors to Italy who want coloured postcards may be offered something more satisfying than the old German wares, and that some of the huge trade in postcards with that country may pass into our hands. Several firms exhibited good examples of work executed by the three-colour process, notably the Photochrome Company of Tonbridge Wells, and most of the best known Christmas card producers sent exhibits. The British Fine Art Company, of South Street, Hammersmith, displayed specimens of a clever process by which not only can oil paintings be reproduced so as to show brush marks in relief and look to the casual observer like the original picture, but watercolours, colour prints, etc., can be so rendered as to give the effect of oil paintings. The result is certainly extraordinarily like oil painting, but whether the ingenuity required to produce a texture to which the reproduction seems to have no particular right, could not have been expended to better purpose is a different question.

Pottery.—There were several interesting exhibits in the pottery section. Amongst these the little show of the Pilkington Tile and Pottery Company, of Clifton Junction, near Manchester, was perhaps the most noteworthy. The large orange-vermilion pots, placed on either side of the entrance, were brilliant pieces of colour which called attention from a distance to a rather small and not particularly well-placed stand. The case of painted lustre in the foreground, though it only contained a few objects, was worthy of the closest attention. The little bowl bought by Her Majesty the Queen was an example of the most exquisitely delicate colouring, the clever model of the child and the cock a specimen of rich and daring colour; the captive slaves, glazed with a beautifully deep lustre, were perhaps a trifle restless and did less justice to the quality of the lustre colour. The Lancastrian ware in the background was good in shape and represented a large range of colourings, and the lustre tiles on the walls suggested the joy of sitting by a fire which would light up such mines of colour. Amongst the firms producing lustre ware must be noted Messrs. Moorcroft, of Burslem, whose matt lustre effects were many of them very satisfactory, and Messrs. Josiah Wedgwood and Son, of Etruria, whose lustred porcelain was very dainty. The broken colour of many of the bowls was very subtle, and the gilt on the outside helped the effect. There is no doubt of the beauty of the work, and yet one feels that there is a certain waste in adding lustre to porcelain. An ordinary earthenware body is not a joy in itself and calls for something beautiful to cover it; fine porcelain, on the other hand, has qualities which are at any rate partially lost under a lustre glaze. Some of the dessert and dinner ware exhibited by the same firm was very satisfactory; the powdered colours were particularly successful, and the adaptation of a Rouen pattern without the unpleasantness of a tin glaze deserves to be popular. The deep orange flambé of the Crown Staffordshire Porcelain Company, Stoke-on-Trent, is remarkable for the quality of its colour. Mr. W. Howson Taylor, of West Smethwick, showed a collection of Ruskin ware, amongst which were some pots giving really fine broken colour effects. Some of the Upchurch ware was also satisfactory, and several firms exhibited pleasing "art pottery," more or less of the peasant type—notably Mr. Barron, of Barnstaple, and Messrs. Brannam, of the same town.

Toys.—The toys on the whole were a trifle disappointing, perhaps because last year's fair had raised rather high hopes. It looked as though innumerable manufacturers were trying to do the same thing, whilst very few were striking out on anything approaching new or original lines. There seemed to be a plethora of "soft goods," especially of teddy bears, all conceived and carried out on very much the same lines. Sloan and Company, of Liverpool, had some quite original beasts and birds, including some truly fascinating geese, and their bedspread with appliquéd animals in the round would not only give joy to any child, but was cleverly and artistically conceived and carried out. Some of the wooden toys were both clever and artistic, and the model villages, Noah's arks and fairy stories exhibited by the Lord Roberts' Memorial Workshops for Disabled Soldiers and Sailors made one long to play with them, and spoke volumes for the controlling spirit of this department of their work. The puzzles of the Aldon Studios, Regent Street, included pictures by such well-known English masters as Walter Crane and Randolph Caldecot, which were not only pretty when put together but eminently fit for puzzles. When, however, one compares the wooden toys and puzzles which we are manufacturing with those which are coming

over in quantities from Japan one cannot but feel that our makers have a very hard task in front of them if they hope to produce as well and cheaply as our Eastern ally. The Japanese toys made expressly for the English market, and as copies more or less exact of European goods, have not the interest of those made by Japanese for Japanese, but they are cheap, and they have very often a definite artistic quality. Nevertheless, it is to be hoped that our toy industry will thrive as never before, and certainly the quantity of British toys shown was very satisfactory. They gave, on the whole, evidence of decidedly more artistic aim than the pre-war toys, but there is still a tendency in certain of them to the rather spooky forms, which are neither beautiful in themselves nor attractive to the average child.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Trade Dislocation.—Complaints of the inability to get delivery of goods within any reasonable limit of time increase, and they promise to go on increasing. The labour, fuel and dyeware shortages which account for most of the delay grow no less severe, and in certain directions congestion has been made the more congested by the impulse to buy well in advance of the requirements of the moment. Estimates of the quantity of machinery standing for want of labour are apt to be misleading, but in a large number of reported cases the proportion is 25 per cent. or more. In these circumstances it need not be surprising that buyers have to grant months where normally they allow weeks for delivery. The outcry is strong while present wants remain unsatisfied, but self-defensive over-buying brings its own reaction later. Meanwhile, the clearing of old and depreciated stocks of goods is assisted, and the necessitous are learning to be thankful for any goods they can be permitted to receive.

Trade Contraction.—Restrictions on the importation of hosiery, silk and lace are expected shortly, and it is understood that the procedure will be by licence. The home production being effectively restricted by other means, it follows that the entire textile trade of the country is to be brought into smaller compass, while the export trade is to be facilitated. The dispensation may be accepted as wise and necessary, although opinion is not unanimous on that score. In any case, the arrangement does not contain much promise of easier prices to the consumer, and it is providential that an unusually large number of consumers are indifferent to the matter of price. The home-distributing business in textiles may be accused of being more sensitive to small influences than to large ones. A trifle like the state of the weather makes more impression than the state of the war, and while this remains the case it dare hardly be professed that the public has got down to the bone of economy in attire.

American Competition.—A significant change in the current of American textile trade has been observed with an unnatural absence of whooping. For the first time in history the United States exports of manufactured textiles have exceeded the imports. The records are a little belated, covering eleven months of last year, and omitting account of subsequent movements which almost certainly accentuate the contrast. The improvement is accepted fatalistically in America as an inevitable and temporary outcome of the war, denoting no power on the American part to make good the ground gained. The reading may be right, but it is not in this mild and helpless mood that trade gains are wontedly regarded.

Credit Systems.—Two hundred manufacturing firms in the British woollen and worsted trade have signed a compact binding them to reform the terms of sale in two directions, and principally in respect of credit. The present time has been chosen to abolish the six-monthly terms that have been prevalent, especially in the sale of the more expensive goods. Customers have ordered in the summer goods for delivery in the autumn for payment in the spring, with the result that the producer has been out of his money for something like a whole year. They are to be required to pay in three months instead of six. Monthly settlements are substituted for seasonal settlements, and the allowances for prepayment or extension are closely defined. The scheme has created commotion amounting almost to revolution, and it is one which could not be carried through were the communal instinct not especially strong at present among manufacturers. An arrangement that makes the producer virtually the banker of the merchant and tailor is patently disadvantageous. Even the three-monthly credits remaining contrast strongly with the fortnightly settlements upon which the cotton industry has grown up.

Trade Measures.—This interference with settled practice does not stand alone. The manufacturers have found courage at last to disown the ancient practices of selling 37 inches to the yard and of allowing one-quarter yard in every ten yards. The uprooting of this custom may conceivably cost as much in disorganisation as it is worth. The cumbrousness and indivisibility are not to be denied, but men who have thought and calculated in 37-inch terms from the beginning do not readily accustom themselves to a change. The alteration of measuring apparatus in the form of tables, sticks and machines, although a fairly considerable task, is not the worst of the matter. The antiquity

of the irregular measures of the textile trade is imperfectly realised by the generality of traders. *De Ponderibus et Mensuris*, one of the earliest Norman statutes, prescribed that in every hundred ells of canvas or linen there should be six score ells. In the fifteenth century it was statutory that in the woollen cloths called Dozens there should be at least 14 yards 14 inches. Thus at this early time of day the 37-inch yard was recognised, and it was complained that London merchants were dissatisfied with that allowance, claiming in addition to the added inch, "a sauft, a powder or an hauncer." "Where they were wont to measure the Cloth by the Yard and the full inch, now they will measure by the Yard and the full Hand," says the complaint. In the upshot the yard and one inch measure was made obligatory, and a silk line, or cord, sealed at both ends and divided in 37-inch measure was placed in the hands of the aulnagers. In the sixteenth century it was enacted that clothiers should not put to sale "cloth which when it shall be full wett shall shrinke more than one yerde in all the lengthe." Either in this sanction or in one made a generation later when a concession of 1½ yards was allowed, may be descried the origin of the trade allowance known variously as the yard per piece or the quarter-in-ten. It is somewhat difficult to believe that customs so tenacious of life can be doomed actually to die on July 1st, in accordance with the edict of the two hundred manufacturers.

A Cotton Annual.—In its eleventh appearance the "Cotton Year Book" (Marsden: Manchester. 2s. 6d.) is distinctly more portly than before, reminding all concerned that the development of cotton machinery is continuous. The departures of the last twelve months have been quiet rather than bold, and in the book they are assimilated to the progress of past years. The process gives something more than a bird's-eye view of the several recognised systems of working, with summary descriptions of the machines and notes upon their working. Annual compends, relating the whole detail of processes in current use, fill a place that makes them probably the most welcome of textile publications. Their handy form and ample scope, their practical hints, definitions and oddments of information, commend them everywhere. Text-books, catalogues, monthly and weekly periodicals have their separate office, and the "Year Book" is the complement of all of them. An orderly *résumé* of cotton-trade practice running to 658 pages of solid matter serves some of the purposes of a library as well as of a book.

Luxuries and Necessities.—Silk manufacturers are not without blame for classing silk as a luxury; there are circumstances in which the description is accurate, but as much might be said of most commodities in this world. Cotton is a considerable luxury in its form of yarn at 45s. per lb., and wool is made into fabrics finer than mere necessity would ever dictate. Silk is hardly a luxury when used as a cheap substitute for wool, as waste tussah silk is now being used in America. In its ordinary employments, say in blouses or neckties, silk represents the best value for money, and this is not the characteristic of a luxury truly-called. As an article of munitions silk approaches the position of a necessity in connection with artillery. Silk is not absolutely indispensable in that field, for apparently woollen cloth is being substituted for silk as a container for cartridges. Any fabric might serve purely as a wrapper, but silk is credited with least effect in assisting erosion in the bore. Mr. Frank Warner has been at some pains to combat the loose impression that silk is all superfluity, and a close examination might show that a very small part of the goods made from silk enter into the class of luxuries. The sewing silks for Army uniforms and the woven neckerchiefs for the Navy are obviously not of that class, and for many years it has been held that far the largest proportion of British-spun silk enters into goods of a mixed nature sold at comparatively low prices. Not origins but uses determine the fact of luxuriousness. Jute is presumably a luxury when it is used to make figures on a brocade, although free from imputation when converted into a sandbag. Linen is turned into damasks as well as into aprons, and immense quantities of work are put into cottons without benefit except to appearances. In the hunt for luxuries the one important fact is to know what the raw stuff becomes, and any other line is bound to lead astray.

NOTES ON BOOKS.

COMBINATORY ANALYSIS. By Major P. A. MacMahon. Vol. I. pp. i-xx. 1-300. Cambridge: at the University Press. 1915.

In a certain sense all mathematics is a game. You make your own rules, subject only to the condition of their being mutually consistent, and your object is to produce a work of art, such as a double-dummy problem by Lewis, or an all-round break at billiards, like one by John Roberts in his prime. The theory explained in this book arose and developed from a variety of pastimes and problems connected with them—bell-ringing, games such as draughts, chess, and piquet; calculation of odds against particular throws of one or more dice, and so on. Many of Mr. Dudeney's puzzles in the *Strand Magazine* depend upon combinatory analysis, or, as Sylvester called it, "tactic." It is not easy to define its scope exactly; but we may say, in general terms, that it deals with all questions about arrangements or selections of

objects, and, for convenience, is taken to include the theory of partition of numbers, though this is more properly an application of it. We find the first outlines of the theory in Pascal, Fermat, and Euler; then for a long time it hibernated, so to speak, in two chapters of text-books on algebra—"Permutations and Combinations" and "Probability"—until it became of unexpected importance as an auxiliary in two great fields of research, namely, the theory of groups and that of the invariants of algebraic forms. Euler seems to have been the first to hit on the brilliant idea of a generating function, bottling up, so to speak, a sequence of integers into an expression which is either a rational function of one or more umbral symbols, or, at any rate, an analytical expression which is capable of equivalent transformations. For instance, the formal expansions

$$(1-x)^{-1} = 1 + x + x^2 + \ldots + x^n + \ldots$$
$$(1-x)^{-2} = 1 + 2x + 3x^2 + \ldots + n\,x^{n-1} + \ldots$$

give $(1-x)^{-1}$, $(1-x)^{-2}$ as generating functions of the sequences (0, 1, 2, . . .), (1, 2, 3, . . .) regarded as indices or coefficients respectively. Cayley, Sylvester, and Hammond largely used such equivalences in discussing complete systems of covariants and their independent syzygies.

There are two outstanding features of the present work. The first is the way in which the author contrives to make the theory one organic whole, and at the same time to discuss a great variety of problems which do not obviously fall within its scope. The chapters on chess-board arrangements and on the Latin square illustrate what we mean: so do the discussions of the *problème des rencontres* and the *problème des ménages*. The second is the author's extraordinary power of generalising, especially when dealing with generating functions. As a mathematical theory develops, the problems which it suggests become more and more complex, and the apparatus required to solve them becomes more and more elaborate. Thus in the theory of invariants, Gordan invented and perfected by years of toil his transvectant formulae, which are practically indispensable if we wish to construct a complete system for a binary form of degree higher than 6. Looking at this analytical engine, we are impressed much as we are by a spinning-jenny; we may breathe a sigh of regret for the vanished wheel, spindle, and distaff, but in this age of science we must use the new machine. Major MacMahon has invented a "master-theorem" which seems likely, in capable hands, to effect, in this theory of tactic, the same sort of metallurgic reduction as Gordan's formulae do in the other. In any case it is a very remarkable instance of formal equivalence in the field of rational algebra.

As recently pointed out by Professor Love, there is such a thing as mathematical style. In this respect Major MacMahon is impeccable, especially in the cardinal virtue of lucidity. Moreover, he sets an example which might be more often imitated than it is, and is of great help to the beginner. Besides stating and proving his general theorems, he gives particular cases in illustration, and he always illustrates his definitions when possible.

Not only by this book, but by his numerous original papers, Major MacMahon has proved himself easily first among his contemporary combinarians; so far as we know, he is only equalled (in this field) by Fermat, Pascal, Euler, E. Lucas, and Sylvester. And he is certainly the first to *methodise* the theory. All who are interested in the subject will eagerly look forward to the completion of this highly delectable and artistic work.

PRIVATE HOUSE ELECTRIC LIGHTING. By Frederic H. Taylor. Sixth Edition. London: Percival Marshall & Co. 1915.

The third edition of this convenient manual was reviewed in the *Journal* in July, 1909,* and it was then recommended to those using the electric light or contemplating its installation. Probably in the six years which have passed a good many people have transferred themselves from the latter category into the former, but the recommendation still holds good. The claim on the titlepage that the book has been rewritten may be a little excessive, but parts of it certainly have been rewritten, and the whole has been brought down to date, with considerable additions as regards alike the letterpress and the illustrations. The old arrangement has been preserved, and the non-expert reader will probably find all the information he is likely to require about installation, lamps, fittings, generators, etc.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, 1916.

This bulky volume has suffered but little from war conditions, for the 1068 pages of last year have only been reduced by 87, and there should be enough left to satisfy the most ardent photographer. The almanac was started as a slim volume in 1860, and it has steadily grown in size and value ever since. It has outlived more than one competitor, and bids fair to hold the field for another half century. It includes the usual information, and is certainly the most useful book of reference a photographer can have. The principa article is by the editor, Mr. G. E. Brown, "Practical Notes on Printing Processes." About the year 1884, when describing the then newly proposed process for substituting gelatine for albumen as a medium for the sensitive salts, the present writer remarked that while great improvements had been made in the production of negatives, there still remained but one common method of printing positives, that in which albumenised paper was used, since carbon and platinum were employed only to a comparatively small extent. Mr. Brown begins his essay with a somewhat similar remark

* See *Journal*, Vol. LVII. p. 693.

that "for some years past there has been comparatively little done in the way of originating new photographic printing processes," but he might have added that those processes were numerous enough already.

In addition to this, there is the usual "Epitome of Progress," an account of the principal inventions and novelties of the past year, together with formulae, tables, etc., and all sorts of miscellaneous information likely to be useful to photographers.

A new feature in this year's almanac is an account of "British Resources in the Manufacture of Photographic Materials and Apparatus." This is a *catalogue raisonné* of the photographic manufacturers of the Empire and its allies.

As usual, a notable feature is provided by the advertisements, which form a complete photography directory. As they are placed at the beginning as well as at the end of the book, they render it needful for the titlepage to be postponed to page 335, a somewhat unusual position.

THE TROPICS. By C. R. Enock, F.R.G.S. London: Grant Richards, Ltd. 16*s*.

For some years Mr. Enock has been endeavouring to familiarise the world with a new science, which he styles "constructive human geography." He has read papers on it before the Royal Society of Arts, the British Association, and other bodies; but in case there are any who are still ignorant of the scope or meaning of this term, it may be as well to begin this notice by an attempt to define it. Mr. Enock, it seems, has been struck by the fact that while Nature is extremely prodigal of her gifts in many parts of the world, a considerable proportion of the human race live on the border-line of poverty, or below it. The object of his "constructive human geography," if we understand it aright, is by a scientific reorganisation of the industries of the earth to secure among its inhabitants a fair division of the results of their labour. The idea, it will be seen, is not wanting in boldness nor in magnitude: how far it is practicable is another question.

Before one can set about the scientific reorganisation of the industries of the earth, it is necessary to gain a clear idea of existing industries and the possibilities of further development. By far the greater part of this volume consists of a review—geographical, historical, and economic—of that huge belt of the world known as the tropics. It is not quite clear to us why the author has prescribed himself even these limits, for although "The Tropics" cover about one-third of the surface of the globe, it seems to us that the other two-thirds (or the greater part of them, at all events) have an equal right to be included in the new science. However, when the author has given us so much, it may seem ungrateful to complain that he has not given us more.

Mr. Enock has travelled widely, and those who have read his "Great Pacific Coast" and "The Andes and the Amazon" will know that he has the gift of keen observation and the power of recording what he has seen in a vivid and picturesque style. The present volume scarcely affords so much scope for his literary qualities as his earlier works, which for the most part recorded his personal experiences; it is naturally more encyclopædic in character, and is less the result of first-hand knowledge. But it contains a great amount of information, carefully put together, and is rich in suggestions as to the future development of the various countries which he describes.

GENERAL NOTES.

REPORT ON THE CONSULAR DISTRICT OF ROME FOR 1914.—The works of the new railway line from Rome to Naples are progressing, but somewhat slowly, and it is to be foreseen that the line will not be opened to traffic until late in 1916, though the most difficult part of the work from an engineering point of view seems to have been completed some time ago. An electric line is being built by an Italian company in the province of Rome, and will join the Italian capital with the famous mineral springs of Fiuggi, to be extended later on to other towns of the province, such as Alatri, Guarano, etc. The difficulty experienced during the latter part of 1914 in securing coal required by the various Italian factories, and the consequent rise of price, have been the subjects of much discussion in the Italian press. It has been suggested that in order to make local factories to some extent independent of foreign coal, the Government should encourage the exploitation of the lignite mines which are found in various parts of the country. The mines at present being worked yield about 1,300,000 tons per year, but the output could be increased to about 5,000,000 tons if the exploitation of all the mines in the country were encouraged by facilities in the way of reduced taxes, special freight rates, etc. It is estimated that the value of the coal purchased by Rome alone amounts to over £1,000,000 a year, and one-fifth of that amount could be saved if the use of lignite were resorted to on a larger scale. A recent report on the earthquake of January 13th, 1914, has been submitted to Parliament, and states that about 30,000 persons lost their lives, of whom 20,000 were in the province of Aquila alone. The Government granted certain facilities in the way of exemption from taxes, moratorium, etc., as well as a sum of £12,000,000 to be spent for the relief of the survivors and the building of temporary shelters in the affected districts. The normal commercial activities of the Roman district have been seriously affected since August, 1914,

by the war, especially on account of the absence of the customary visitors. In former years these used to flock in large numbers to the Italian capital at the beginning of the autumn, and a great many of them spent their winter there. Their absence has been seriously felt by the numerous hotel-keepers, tradesmen, etc., who are almost exclusively dependent upon their foreign *clientèle*.

PRINCESS OF WALES' SCHOLARSHIPS.—**The Board of Education announce that, as the National Competition is not this year available as a basis for award of the Princess of Wales' Scholarships, they will award one or two of the scholarships on the basis of the Examinations in Art to be held in 1916. The conditions will be, with certain modifications, identical with those for local scholarships for art.**

TREATMENT OF SNAKE-BITE.—In a paper on "Studies on the Treatment of Snake-Bite: the Present Position of Antivenene Therapy," which appeared in the October issue of the *Indian Journal of Medical Research*, Captain H. W. Acton and Captain R. Knowles, I.M.S., come to the following conclusions: With the remedies at present available for the treatment of bites from poisonous snakes, if properly applied, it should be possible to save a large percentage of the cases which now prove fatal. The general line of procedure should be as follows: (1) Apply a firm ligature immediately. (2) Impregnate the whole area of the bite with a hypodermic injection of a strong solution of gold chloride. (3) Inject from 100 to 200 c.c. of antivenene intravenously, if the biting snake be suspected to have been a cobra or Russell's viper. If symptoms of venom intoxication come on, further and even larger injections of antivenene should be given intravenously. With sera concentrated ten times, a dose of 20–60 c.c. should save every case of cobra bite.

THE EASTERN HEMLOCK OF NORTH AMERICA.—The eastern hemlock (*Tsuga canadensis*, Linn.) occurs in the white pine region of eastern North America and extends from Nova Scotia to east central Minnesota in the west, and to northern Georgia and Alabama in the south. Though excelled in most respects by other trees in the region of its growth, it is none the less a most important member of the remaining old-growth forests. Its lumber serves many purposes for which pine was formerly demanded; its wood supplies more raw material for paper pulp than does any other in the United States except spruce, while the amount of its bark used in the United States for tanning exceeds that of all other native species combined. It is, however, a slow-growing tree, and it will not pay to encourage its reproduction on fertile soil where a good deal of the remaining old-growth hemlock timber at present exists, if it is suitable either for agriculture or for raising timber crops of rapidly growing species. In *Bulletin* No. 152, 1915, *U.S. Dept. Agric.*, a full account of the characteristics and distribution of the tree is given, together with information as to the amount and value of the standing timber in the United States, its utilisation for lumber, pulp, tanning bark and other purposes, forest management, etc.—*Bulletin of the Imperial Institute.*

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

MARCH 29.—R. W. SETON-WATSON, D.Litt., "Pan-German Aspirations in the Near East." SIR EDWIN PEARS will preside.

APRIL 5.—ARTHUR S. JENNINGS, "Painting by Dipping, Spraying, and other Mechanical Means."

MAY 3.—PROFESSOR W. B. BOTTOMLEY, M.A., F.C.S., F.L.S., "Bacterised Peat."

MAY 10.—SIR FRANCIS TAYLOR PIGGOTT, M.A., LL.M., Chief Justice of Hong-Kong, 1905–1912, "Contraband and Blockade." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council of the Society, will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

APRIL 27.—JAMES MACKENNA, M.A., I.C.S. (Deputy Commissioner, Myaungmya, Burma, and designated Agricultural Adviser to the Government of India), "Scientific Agriculture in India."

MAY 18.—SARDAR DALJIT SINGH, C.S.I., "The Sikhs."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

MARCH 28.—PERCY HURD, "Next Steps in Empire Partnership." DUGALD CLERK, D.Sc., F.R.S., Chairman of the Council of the Society, will preside.

APRIL 11.—SIR DANIEL MORRIS, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Timber Resources of Newfoundland." The Right Hon. SIR WILLIAM MACGREGOR, P.C., G.C.M.G., C.B., will preside.

Dates to be hereafter announced:—

JOHN COLLETT MOULDEN, A.R.S.M., M.Inst.M.M., "Zinc, its Production and Industrial Applications." (Peter Le Neve Foster Prize Essay.)

G. P. BAKER, "Hindu Hand-painted Calicoes of the Seventeenth and Eighteenth Centuries,

and their Influence on the Tinctorial Arts of Europe."

PROFESSOR WYNDHAM R. DUNSTAN, C.M.G., M.A., LL.D., F.R.S., "The Work of the Imperial Institute for India." The Right Hon. LORD ISLINGTON, G.C.M.G., will preside.

FOTHERGILL LECTURES.

Monday afternoons, at 4.30 p.m.:—

EDWARD A. REEVES, F.R.A.S., F.R.G.S., Map Curator and Instructor in Surveying to the Royal Geographical Society, "Surveying, Past and Present." Three Lectures.

Syllabus.

LECTURE I.—MARCH 27.—*Historical Sketch.* Introductory remarks—First attempts at surveying—Early surveying instruments and methods—First attempts at measuring size of earth—How early charts and maps were made—Beginnings of astronomical observations for fixing positions—Improvements in instruments and methods introduced in fifteenth century—First triangulation—Survey basis of early British maps—Further improvements in instruments and methods.

LECTURE II.—APRIL 3.—*Present position of Surveying and Mapping of the World.* General account, illustrated by maps and diagrams showing (1) parts of the world topographically mapped from reliable surveys, (2) those less accurately mapped from surveys chiefly non-topographical, (3) parts only roughly mapped from route traverses, and (4) those still entirely unsurveyed—Facsimiles of MS. maps of well-known explorers—Specimens of different kinds of surveys from which the earth has been mapped, with general account of them—Part taken by the Royal Geographical Society in promoting exploration and surveying—Work of the future.

LECTURE III.—APRIL 10.—*Modern Instruments and Methods of Geographical Surveying.* Advance made in recent years—Difficulties of obtaining accurate measurements—Circumstances that determine character of survey—Theodolites—Base line apparatus—Triangulation, with recent examples—Traverses with theodolite and tacheometer or subtense instruments — Plane-table, its use in topographical mapping, and recent improvements—Determination of heights—Photographic surveying—Astronomical observations for fixing positions.

The lectures will be illustrated with lantern-slides.

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m.:—

J. ERSKINE-MURRAY, D.Sc., F.R.S.E., M.I.E.E., "Vibrations, Waves, and Resonance." Four Lectures.

May 1, 8, 15, 22.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 27...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Fothergill Lecture.) Mr. E. A. Reeves, "Surveying: Past and Present." (Lecture I.)

Farmers' Club, Whitehall-court, S.W., 4 p.m. Mr. H. T. Eve, "County War Agricultural Committees."

TUESDAY, MARCH 28...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Mr. P. Hurd, "Next Steps in Empire Partnership."

Royal Institution, Albemarle-street, W., 3 p.m. Professor F. Keeble, "Modern Horticulture. Lecture I.—Plants and the Seasons."

Anthropological Institute, 50, Great Russell-street, W.C. Joint meeting with the Prehistoric Society of East Anglia. 2 p.m. 1. Dr. A. E. Peake, "Grimes Graves and Allied Cultures." 2. Mr. A. S. Kennard, "The Pleistocene Succession in England."

5 p.m. Miss N. Layard, "Hand Grips." 2. Rev. F. W. Hayes, "Irish MS. and other Evidence of the Use of Stone Weapons, including Smooth Stone Celts within Historic Times."

Colonial Institute, Hotel Cecil, Strand, W.C., 4 p.m. Mr. E. S. Bruce, "The Aëroplane and its Use in War."

WEDNESDAY, MARCH 29...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Dr. R. W. Seton-Watson, "Pan-German Aspirations in the Near East."

Sanitary Institute, 90, Buckingham Palace-road, S.W., 4.15 p.m. Mr. G. M. Pettit, "Made-Down and Tenemented Houses."

Metals, Institute of, at the Chemical Society, Burlington House, W., 4 p.m. Annual Meeting. Address by the President.

8 p.m. 1. Third Report to the Corrosion Committee. 2. Mr. E. Cumberland, "The Electrolytic Method of preventing Corrosion." 3. Professors A. A. Read and R. H. Greaves, "Note on some Tin Aluminium-Copper Alloys." 4. Mr. W. B. Withey, "Notes on the Analysis of Aluminium and its Alloys." 5. Mr. F. C. Thompson, "The Annealing of Nickel Silver." 6. Professor A. Stansfield, "Electric Furnaces as applied to Non-ferrous Metallurgy." 7. Drs. N. S. Kurnakow, S. Zemczuzny and M. Zasedatelev, "Transformations in Alloys of Gold and Copper."

THURSDAY, MARCH 30...Royal Society, Burlington House, W., 4.30 p.m.

Child Study Society, 90, Buckingham Palace-road, S.W., 6 p.m. Mr. C. M. Chapman, "The Child Delinquent."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. W. H. Hadow, "English Music in the Tudor Period. Lecture I.—Church Music."

Camera Club, 17, John-street, Adelphi, W.C., 8 p.m. Mr. M. Adams, "Both Sides of Child Life, expressed by my Camera."

FRIDAY, MARCH 31...Royal Institution, Albemarle-street, W., 5.30 p.m. Professor A. Fowler, "The Spectra of Hydrogen and Helium."

Sanitary Institute, Physics Theatre, University, Liverpool, 3.30 p.m. Professor J. M. Beattie, "Tubercular Disease of Children and Milk Supply."

SATURDAY, APRIL 1...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Radiations from Atoms and Electrons." (Lecture IV.)

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—March 24, 1916.

Journal of the Royal Society of Arts.

No. 3,306. VOL. LXIV.

FRIDAY, MARCH 31, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

NEXT WEEK.

MONDAY, APRIL 3rd, 4.30 p.m. (Fothergill Lecture.) E. A. REEVES, F.R.A.S., F.R.G.S., Map Curator and Instructor in Surveying to the Royal Geographical Society, "Surveying: Past and Present." (Lecture II.)

WEDNESDAY, APRIL 5th, 4.30 p.m. (Ordinary Meeting.) ARTHUR SEYMOUR JENNINGS, F.I.B.D., "Painting by Dipping, Spraying, and other Mechanical Means."

PROCEEDINGS OF THE SOCIETY.

SIXTEENTH ORDINARY MEETING.

Wednesday, March 29th, 1916; SIR EDWIN PEARS in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Adenwala, Moteeram Heerabhoy, Heera Bag, Shahibag Post, Ahmedabad, India.

Kale, Professor Vaman Govind, M.A., Fergusson College, Poona, India.

Khan, M. A. Lateef, Furhut Munzil, Saifabad, Hyderabad, Deccan, India.

The following candidates were balloted for and duly elected Fellows of the Society:—

Kewley, James, M.A., Cambrian Lodge, Portishead.

Walker, Basil Woodd, M.D., 6, Dawson-place, Pembridge-square, W.

The paper read was—

PAN-GERMAN ASPIRATIONS IN THE NEAR EAST.

By R. W. SETON-WATSON, D.Litt.

It has become a commonplace of writers on the war to say that Germany is a danger to Europe. In a sense this is of course true, but it gives a wrong focus to the truth. For no nation, so long as it is content with its national unity and independence and the development of its own resources and culture, can fairly be described as a menace to its neighbours. That stage is only reached when it begins to regard its own civilisation as a species of superculture, and its leaders as supermen who have the mission of imposing their wishes and ideas upon the outside world. It is not, then, Germany, *as Germany*, that threatens Europe's whole future. There have been cases before in history, when a great nation went mad for a time and yet recovered from its madness. The classic example is that of our nearest and dearest Allies, the French, during the orgies of the Reign of Terror. And it may be that in the same way Germany will recover from the madness which has devastated Belgium, Poland, and Serbia, and that some intercourse between her and her neighbours to the West and East will again be possible. At a moment when her submarines and Zeppelins are murdering at random, and her soldiers are drugged with ether for the assault, this may appear little better than a pious hope.

But to-day the essential fact with which we have to reckon is that Germany is more united than ever before, and that the classes which control her destinies—not merely the narrow military clique at the top, but the whole vast organism of the bureaucracy, army, and professional and academic classes—are inspired by a programme which may be summed up in three words—*Deutschland ueber Alles*. Fortunately this has at last become too obvious to be ignored, and is, indeed, only contested by a few cranks, who have been far too often wrong in their estimates and prophecies to obtain credence now. Strangely enough, however, the real urgent menace from Germany has been, to a large extent, overlooked by our public opinion or merely alluded to in passing. This menace lies in the fact that Germany controls the destinies

of the 51,000,000 who inhabit the Austro-Hungarian Monarchy—to say nothing of the 20,000,000 of Turkey and the 4,000,000 of Bulgaria—and is ruthlessly exploiting them in a cause which the vast majority of them regard with complete indifference, and at least half of them with utter loathing. Just as the harmless Anatolian peasant is fighting the battles of Enver Pasha—the murderer of his commander-in-chief, his Grand Vizier, and now the heir-apparent—so the thirty-five million Slavs and Latins of the Central Empires are being used as "food for cannon" in a death struggle against their own kinsmen and their dearest national ideals. Thus the main task before us, if we are really to reconstruct Europe on new and healthy lines, must be to detach these peoples from their present thraldom to Berlin, Vienna, and Budapest, to liberate the Slav democracies of Central Europe, and to secure to them the means of progress and organisation upon a national and independent basis. This task has the further military advantage that it enables us to attack Germany at her weakest, and no longer at her strongest, spot; for the events of the war have only served to prove that some of the leading French strategists were right in maintaining that the true field for a successful offensive lies through the great Hungarian plains, not through the brick walls of Belgium. By our planlessness and levity we have abandoned the magnificent natural frontier from the Adriatic to the Danube, which was at our disposal for the first fourteen months of the war, and we did not even take the trouble to defend Mount Lovčen, the key of the Adriatic, from the assaults of Austria. But though our folly has made the task infinitely more difficult, it still lies before us. If to the conquering Germans last autumn Serbia was the route to the East, she is also the route to the West for the Allied armies.

Before the war in Germany, as in all other European countries, our own included, there were two currents of opinion, the one definitely opposed to adventure or expansion, the other as definitely basing itself upon force as the root of all progress. No one who visited Germany frequently, or was in the habit of reading German political literature, could fail to be aware of the existence of an active Pan-German movement, and of a propaganda which often assumed an anti-British complexion. Our mistake lay in over-estimating the strength of those saner forces in German public opinion which made for peace. At the end of July, 1914, those forces proved themselves to be utterly impotent, and were swept away by the march of events. The inevitable result has been to bring the Pan-German programme within the range of practical politics and to increase immensely its appeal and its popularity. It may be argued that we were always wrong to ignore its significance; to-day our most vital interests demand that we should study it in all its bearings.

There are three stages in the Pan-German plan: (1) The creation of "Mitteleuropa," a great Central European state-organism of 130 to 150 million inhabitants, as an economic and military unit; (2) the realisation of the dream Berlin-Baghdad, by the inclusion in the political and economic spheres of influence of the new Zollverein of all the territory lying between the Hungarian frontier and the Persian Gulf; and (3) naval supremacy and Weltmacht. The vital problem of this war, upon which the whole future development of civilisation depends, is whether we are to oppose this programme or to submit to it as inevitable. At such a moment there can be no half measures; the answer must be yes or no. If no, this war is an act of criminal folly which has no parallel in history. If yes, we must not wait till the enemy's plan has reached maturity, but must overthrow it in its initial stages. It was a German poet who told us that what we have inherited from our ancestors we must earn again in order to possess (*Was du ererbt von deinen Vätern hast, erwirb es, um es zu besitzen*). That is a lesson which we have been in danger of forgetting, and which Germany is teaching us. For the future we must throw off the insularity which left us ignorant or oblivious of hostile designs, nor must we ever allow a situation to arise in which we might seem indifferent to events upon land simply because they take place at the other end of Europe. For such indifference is the surest way to alienate our Allies, who realise to the full the close interconnection of West and East and South-East, and expect us to realise it equally. If we are right in regarding sea power as the key to victory, it is none the less true that the extension of German land power will be the prelude to a fresh attempt to challenge our security on the sea. That is, of course, the true inward explanation of the presence of British armies upon French soil; but while everyone to-day realises the need of countering the German land plan on the West, the equally urgent and overwhelming need of countering the Germans in the East of Europe has still not been sufficiently realised. There are still quite serious and well-

meaning people who argue that if the Germans could be once ejected from Belgium and Northern France, our aims in the war would be achieved. To them all the vast problems of Central and Eastern Europe are a mere blank. In seeking to differentiate between Germany and her Allies, they fail to realise the fact that it is no mere accident that has brought Prussia, Hungary, Turkey, and Bulgaria into line. All four stand for the same principle of racial hegemony. The only difference lies in the varying degree of crudeness with which that policy is pursued in Posen, in Transylvania, in the Balkans, and in Armenia.

If the German plan of "Berlin-Baghdad" is to be countered, we must find obstacles to place in its path, and in so doing we can only build with the material which is already to our hand. This consists, above all, of the Slav and Latin peoples of Austria-Hungary and South-Eastern Europe generally, who are eager to lead their own national lives, and the fulfilment of whose aspirations coincides absolutely with British interests and the interests of the Entente as a whole. Till the very eve of war, and even later, it was the fashion in certain circles to regret our political ties with Russia on the ground that the Slavs are barbarous. It would be as easy as it is superfluous to prove that the Russians, the greatest of all the Slav nations, are anything but barbarous, and that they have much to teach us all—above all, the Kulturvolk *par excellence*—in every branch of science, art, literature, and music. But my present object is to emphasize that it is an equally gross libel, and in some directions an even grosser libel, upon the other Slav nations also. The next two in importance, the Poles and the Czechs, far from being barbarous, have ancient cultures and literatures of their own, and have played a notable part in European thought and progress. The Slovaks are perhaps the most attractive and naturally gifted of all the Slav nations, and only await the removal of the tyrannous Magyar yoke in order to reveal their latent talents to the world at large. The Serbs and their Croat and Slovene kinsmen, the three branches of the Jugoslav race, are also noticeable, not only for their heroic endurance against fearful odds, but above all for the virile perseverance which has created, without external aid, the most democratic of peasant states in modern times.

One further point deserves special emphasis in this connection, namely, the essential error which underlay our diplomacy in the years preceding the war, in the treating the Balkans and Austria-Hungary as two watertight compartments. It lies quite outside my present purpose to describe the process by which the Germany of the Burschenschaften and Turnvereine, of the Romantic Era in literature, and of liberalism in the Swabian and South German form, was transformed by the genius of Bismarck and his group into the Prussianised Germany against which we are pitted to-day, and which rests upon the material doctrines of blood and iron, and of brute force as the sure forerunner of national prosperity. During the generation which separated the Congress of Vienna from the Revolution of 1848, the aspirations of the leaders of German thought were directed, at one and the same time, towards national unity and constitutional liberty and reform. But the reform movement was shipwrecked at Frankfurt in 1848. Unity was only possible on a unitary basis. Two masters were impossible; either Prussia or Austria had to give way. The idealists of Frankfurt dreamed of a "Great Germany," the Germany of 70,000,000, as they reckoned even then. But the inclusion of Austria with her non-German elements would have created a dangerous dualism and prolonged still further the rivalry of Habsburg and Hohenzollern. Bismarck achieved German unity on rather narrower lines by the elimination of Austria. He achieved it in seven years by three successive wars of aggression, in which appearances were carefully preserved till long after the event. But for his remaining twenty years of office, with the notorious exception of 1875, when he was within an ace of attacking France once more, he favoured peaceful development, and posed as the peacemaker and honest broker. Nor was this a mere pose, and there are no grounds for doubting his sincerity when he applied the famous phrase "satiated" (*saturiert*) to the territorial appetites of Germany; and when he declared that the whole Eastern Question was not worth the bones of a single Pomeranian grenadier. The modern German tendency to repudiate his attitude in this respect has obscured the extremely subtle nature of his policy. The same attitude which, in the Austro-Prussian War of 1866, made him lie in despair upon his bed and tear the bedclothes with his teeth when William I. wanted to annex Bohemia, was reflected in the memorandum which he addressed to William I. in 1871, to the effect that it was far more advantageous for Germany to extend her influence over the Slavs through the medium of Austria than to annex the German

subjects of the House of Habsburg. A whole volume could easily be devoted to a discussion of his motives in 1866, in suggesting that Budapest was a better centre than Vienna for the reconstruction of the Dual Monarchy. But it is quite clear that he aimed at the political organisation of Austria-Hungary as an instrument of German policy; and with that aim always in view the Czechs were isolated, the Poles discreetly held in check, and the Magyars flattered and encouraged. So firmly persuaded was Bismarck of Austria's value to Germany, that when the Eastern Question separated Austria from Russia and forced Bismarck to a decision, he chose Austria without hesitation. Thus arose the Dual Alliance, which in 1882 became the Triple Alliance. Throughout these years Bismarck favoured the league of the three Emperors, and sometimes managed to attain it, though never permanently; and his leanings towards Russia, or the Tsarist system, led him to conclude the famous Reinsurance Treaty (*Rückversicherungsvertrag*). But determined as he was to remain on friendly terms with Russia, he was never prepared to pay the price of deserting Austria.

Bismarck's aim then was slow infiltration. He once said to Hermann Bahr, the novelist, who as a young man headed a deputation of Austrian students: "That he was glad to see that the German Austrians were such good Germans; but that they could not prove this better than by making Austria strong. Germany needed them and reckoned upon them, but *inside Austria*." To-day we are beginning to see the meaning of this policy. On a similar occasion, in 1895, Bismarck said: "To prove effectually your sentiments towards the German Emperor, fulfil all your duties towards your own dynasty. I advise you to show condescension and indulgence to your Slav neighbours." In the same way he steadily discouraged political demonstrations directed against Austria, and in 1897 induced the Reichstag to reject a motion of sympathy with the German nationalists of Austria. In short, he desired a perpetual political alliance between Germany and Austria, if possible, leading to a Zollverein, but very possibly nothing more.

It is sometimes argued that because Germany's present-day ambitions follow quite naturally out of Bismarck's policy, therefore Bismarck was a Pan-German. That is as true and as false as to describe Drake or Nelson as an Imperialist; for every man lives in his own age. It may be that his biographer, Erich Marcks, is right in claiming that Bismarck would be heart and soul with his people in their struggle to-day. But it is difficult to avoid the suspicion that Marcks and many of his compatriots feel, in their heart of hearts, that Bismarck would never have involved Germany in such a war. For to-day Germany is fighting at one and the same time the three wars which her Jingoes would have liked her to fight in succession—the war against Russia and Slavdom, for the domination of Middle Europe and the Near East; the war against France, to silence the promptings of *revanche* and to win the mouths of the Scheldt and the Rhine; and the war against Britain, for sea power and world dominion. Bismarck would certainly have taken them singly. There is another direction, however, in which it is possible to trace the hand of Bismarck on the tragedy of to-day, in his policy of the "strong hand" against the Poles of Posen and Silesia. Despite his platonic advice to Austrian students, he pursued an anti-Slav policy in the most acute and irreconcilable form, and contrived to combine it with a firm league with the Russian Court. Thus under Bismarck we find the curious paradox of Petrograd, inspired by German influence, following an anti-Slav policy in Poland, and thus weakening Russian prestige in the Slavonic world. The Polish partition is the great initial crime which lies at the root of all European troubles for a hundred and fifty years past, and which has committed the three spoilers to the support of an evil situation. Now that Russia has broken with Germany, and is very slowly but noticeably preparing to atone for the crimes of the past, we have the right to expect a complete transformation of Russo-Polish relations, and consequently of the whole situation between the Baltic and the Danube.

The eighties were a period of mild colonial expansion on the part of Germany, but it was not until the accession of William II. that the new era can be said to have begun. Pan-Germanism raised its head and kept pace with the tremendous outburst of economic activity and material prosperity. *Weltpolitik* (world policy) became the new cry, and William himself became its mouthpiece. In 1896, the year of the Kruger telegram, he made one of his most memorable speeches: "Out of the German Empire a world-empire has arisen. Everywhere in all parts of the earth thousands of our countrymen reside. German riches, German knowledge, German activity find their way across the ocean. The duty devolves on you to help me to knit

this Greater German Empire close to the home country, by helping me in complete unity to fulfil my duty also to the Germans in foreign parts." Thus was inaugurated the new Imperialism. The motto of the Great Elector—"Remember that you are a German" (*Gedenke dass du ein Deutscher bist*)—became the motto of Emperor and people. What more natural and estimable than this encouragement of national sentiment? How could we, who were at that very moment engaged in knitting our own Empire more closely together, venture to criticise the Emperor's attitude? What more unexceptionable than William II.'s words, if they had been pronounced by a man of normal temper and not accompanied by a whole series of reactionary and arrogant utterances? It is unnecessary to go through the long catalogue. "*Sic volo, sic jubeo.*" "Him who opposes me I will crush." "Our future lies on the water." "The trident must be in our hands." "The Emperor of the Atlantic to the Emperor of the Pacific." "Peoples of Europe, guard your holiest possessions." "No quarter will be given, no prisoners will be taken . . . Open up once for all a way for Kultur." The last two sentences, incredible as it may sound even to-day, belong to one and the same speech. In William II.'s unbalanced imagination a glorious ideal becomes raucous and rings false. The pure enthusiasm of the patriot soldier-poet, Theodor von Körner, who apostrophised the sword upon his thigh on the evening before he gave his life in the War of Liberation of 1813, becomes the nauseous military sentiment which makes the German Crown Prince proclaim his regret that a cavalry charge at manœuvres is not the "real thing."

The old idea that Germany is "satiated" comes to be more and more keenly repudiated, not only by the Pan-German extremists, but by all the sanest and most influential political writers. We hear more and more of *Kulturdünger* ("the manure of culture"); of the crude gospel of materialism; of the doctrine of the superman and the "strong hand"; of the supreme morality of war; of military strategy as the basis of all political organism and of all international frontiers; of the theory that small states cannot subsist and must inevitably become the prey of the great. That least aggressive and greatest of all German writers, Goethe, once declared that every man had the choice between becoming hammer or anvil. The Pan-Germans caught up this phrase, and preached the view that after being the anvil for centuries the German must insist upon becoming the hammer. The essence of these modern doctrines may be summed up in the teaching of Treitschke—"the State is Power."

One of the main secrets of German success has been those habits of association and co-operation to which their mediæval cities owed much of their prosperity. Just as the student societies played a predominant part in the War of Liberation, so the eighties and nineties which led to the war of Hegemony were a period of the foundation of every kind of patriotic and political society. In 1880 the Deutsche Schulverein was founded in Vienna for the support of German schools, and in the following year its namesake in Berlin was established. The aims of these societies, which are still very active, though perhaps slightly less powerful since the year 1895, were by no means confined to preserving the German position in such mixed districts as Bohemia, Silesia, Posen, Hungary, and Styria, but also to propagating in the intensest manner possible the German idea all along the non-German borderland. An older society, the Gustav-Adolf-Verein, has devoted itself to the support of German Protestant congregations in difficulties, and has done splendid work against Magyar aggression; but, despite its genuinely Protestant zeal, it must be regarded as an eminently political organ. The three colonial societies—the German Colonial League, the German Colonial Society, and the Society for German Colonisation—have all exercised a very marked influence upon public opinion in Germany. The so-called *Schützvereine* (Leagues of Defence), which sprang up in every direction throughout the Polish districts of Germany, the German and mixed districts of Bohemia, and the countries lying between Vienna and the Adriatic, have at one and the same time strengthened the German element wherever it was forced upon the defensive, and intensified the racial struggle by every kind of offensive tactics. Above all, the notorious Deutsche Ostmarkenverein (1894), which has acquired the nickname of the "Hakatist" League from the first letter of the names of its three founders Hansemann, Kennemann, and Tiedemann, led a fierce and merciless attack upon everything Polish—schools, traditions, culture, religion—and became the foremost champion of the brutal policy of land expropriation pursued by the Prussian Government.

There is, however, one society which has attained special notoriety and which deserves fuller treatment, because though often pooh-

poohed even by quite serious Germans before the war, and though always ahead of German public opinion, and indeed extravagant and fantastic in its aims and utterances, it has, in this present war, come into its own, and proved, not only to Germany but to all Europe, that its vapourings and frenzy are not merely Utopian, but *Realpolitik* of the grimmest kind. This is the Pan-German League, which, first founded in 1886 by the notorious Dr. Carl Peters as the Allgemeine Deutsche Verband, to encourage colonial expansion, was transformed in 1895 by Dr. Hasse, the deputy for Leipzig, into the Alldeutsche Verband. Its programme was one of expansion and dominion, of the community of all branches of the German race (*Gemeinschaft aller deutscher Stämme*). It favoured the restoration of the ancient frontiers of the mediæval Empire, the redemption of all German outposts at the expense of the enemy at the gates, the consolidation of Central Europe on a Teutonic and at the same time on an economic basis. It worked through perpetual meetings and agitation, and the noisy cries of its platform orators were reflected in its official organ, the *Alldeutsche Blätter*. It would be very easy even to-day to exaggerate its influence in the years preceding the war. But it certainly acted as a permanent stimulant to the Government, especially in matters of emigration and colonial expansion. Above all, it stirred up public opinion and accustomed it to think of world-problems which had hitherto lain outside the German ken. It would not be accurate to assert that William II. encouraged the League, but he has always worked upon parallel lines. Another famous speech, delivered in 1898, in which he urged "the unity and co-operation of all the German tribes," aroused special enthusiasm in Pan-German circles owing to its use of the central phrase in the League's programme. The agitation of the Pan-German League unquestionably paved the way for the first Navy Bill and popularised the German fleet, especially in Bavaria and the south. Its programme may be summed up under three main heads. No German must be de-Germanised, or lost to his nationality; the fleet must form the link with all Germans overseas; and an active Pan-German propaganda must prepare the colonisation of Central Europe.

Before the war there was a widespread tendency in this country to speak of the Germans as incapable of colonisation. This cheap contempt for a rival who has since become an active enemy is a very dangerous theory. It may be true enough of the particular territory acquired in Africa by the Prussianised Empire of the Hohenzollern; but it is most emphatically not true as an historical statement. Indeed, the growth of such a theory is due to our neglect of European history, and of the racial facts which underlie and explain that history. The very name of Prussia is Slavonic. Berlin is built on territory once occupied by Wends, Obotrites, and other vanished Slav tribes. Pomerania, which derives its name from the Slav Pomorska (Shoreland), was only Germanised in the seventeenth century. The twin dynasties of Mecklenburg are purely Slav in origin. The Mark of Brandenburg is sprinkled with Slav names. East Prussia was Germanised by fire and sword by the Teutonic Knights and the Knights of the Sword, and as a result the Baltic provinces of Russia fell under the dominion of a German landed aristocracy, which retained its influence upon the Russian Court till the very eve of war. The great seaport of Riga has been a centre of German influence, and Dorpat University was purely German till less than a generation ago. The name of Austria—Oesterreich—signifies the East Mark, the outpost of Germanism in its early struggles against Celt and Slav; and much of the present German territory of Austria has only acquired its present racial character as the result of centuries of strife. Since the beginning of history Bohemia has been the battle-ground of Slav and Teuton, and a notable field of German colonisation. In the north of Hungary there is scarcely a town which was not founded by German settlers and does not preserve to this day much of its German character. In Transylvania the virile little Saxon colonies have preserved their national identity since the twelfth and thirteenth centuries. In the kingdom of Hungary as a whole there are to-day over two million Germans. There are German colonists even in Rumania, in the delta of the Danube and in the northern valleys of Bosnia; while in South Russia and the Caucasus they are numbered by the hundred thousand. Thus the *Drang nach Osten*, so far from being a new event in history, dates back eight centuries and more. It is a commonplace to say that nationality in its modern sense is a very recent development; but that does not mean that national consciousness was non-existent in earlier centuries. Even in this island, Scotland and Wales are a proof to the contrary. For a thousand years past a fierce racial struggle has raged between Germans and Slovenes in the Styrian Alps and

the Karst, between Germans and Czechs in Bohemia and Moravia; and since 1850 this struggle has been intensified tenfold. The present war is perhaps its supreme expression; for it is essentially a national war, upon whose issue will depend the future development of the Slav and Teutonic races.

We must not, then, despise the Germans as colonists. They may not be suited for Africa or Australia; but for Europe they most emphatically are. And if they are formidable to-day, it is, as we have seen, above all because they control the destinies of so many millions of alien race who are liable alike to military and economic exploitation, and may at any moment become the victims of a policy of assimilation and colonisation. The only sure way to curb them, and to reduce them within reasonable limits, is to free from their control those other races which, though weaker, have an absolute right to as free an existence and development as the Germans themselves.

Wars and revolutions are thought out in conspirators' garrets and in professors' studies and class-rooms. Mazzini made United Italy possible. Adam Smith laid the foundations of the British mercantile system. Despite our many Empire builders, it was Dilke and Seeley who first taught us to think Imperially. In the same way, Treitschke and Sybel, List and Mommsen, kindled the modern Prussian tradition. Nowhere has the professor, and above all the historian, played the part of the prophet more effectually than in Germany. In the words of one of the ablest German political thinkers, Friedrich Naumann, "When I speak of the historian as the trainer for politics, I see on his right hand the philosopher and on his left the poet."

The German national movement of a century ago is one from which no impartial student of history can refuse his sympathy and admiration; and the figures of Stein as statesman, Fichte as philosopher, Arndt and Körner as poets, Jahn as organiser of patriotism, cannot be held responsible for their brutal and degenerate descendants. Unhappily, the dream of German unity was not to be realised by the admirable methods of South German liberalism, but by the blood and iron of the Prussian Junker. Our natural detestation for the one need not blind us to the merits of the other, as originally conceived; but it is also necessary to point out that even among the idealists who gave to the War of Liberation its inspiration and its programme, the first traces of the modern Pan-German doctrine may be detected. Arndt regarded the fate of small nations as sealed; his whole outlook was vitiated by the theory that the Rhine from source to mouth is the heritage of Germany—a theory which, of course, involves the disappearance of Holland and Switzerland. "The German," he argued, "warlike, enterprising and resolute, has been created to co-operate in the domination of the world"; and his natural mission is one of colonisation. "Turnvater" Jahn, whose influence upon the youth of Germany in the first half of the nineteenth century was incalculable, dreamt of banishing Austria and the Habsburgs to Belgrade and Semlin, and argued that the Pan-German capital must be erected "halfway between Geneva and Memel, between Trieste and Copenhagen, between Dunkirk and Sandomir." It was on this generous basis that he dreamt of erecting German unity.

Parallel with the epochmaking work of Clausewitz, who placed the teachings of strategy upon a modern scientific basis, we find the less profound, but still highly significant writings, of Dietrich von Bülow, who evolved an elaborate theory of political strategy as the true basis of all modern statecraft. His influence can be traced down to the present day, especially in two of his favourite contentions—that only offensive wars can hope to succeed, and that small states are doomed to inevitable extinction.

One of the foremost links in the chain of Pan-Germanic doctrine was the famous economist Friedrich List, who inspired that policy of economic union—or "Free trade within the Empire," to use a more modern phrase—which was a necessary preliminary to German unity in 1871. It was List who said, over two generations ago: "He who has no share on the seas is shut out from the good things and honours of this world. He is a stepson of God." He, like Treitschke after him, declared that Holland can only hope to regain even part of her former prosperity by union with Germany. To him the "Continental System" of Napoleon ceased to be a monstrous idea, if Germany, not France, could be made the centre of economic union. The Continent must be organised as a unit against Britain on the one hand and Russia on the other. It was List also who preached and foretold an union of hearts between Germans and Magyars, and Turkey's destiny as the heritage of Germany.

Another of the founders of modern Germany, Hellmuth von Moltke, as a young man travelled

in the East, and resented the complete absence of German influence. In his writings he favoured the foundation of a German principality in Palestine, and expressed the hope "that Austria will maintain the rights and safeguard the future of the Danubian countries, and that Germany will finally succeed in liberating the mouths of her great rivers," *i.e.*, the Rhine and the Danube. Here we already see the germ of "Berlin to Baghdad" in the earlier form "Rotterdam to Constantinople."

The literature of Pan-Germanism deserves closer attention than it has hitherto received in this country. I do not refer to such wild lucubrations as "Germania Triumphans," "The Reckoning with England," "The Coming War"; for mountains of such trash have appeared during the last twenty years both in Germany and in England, and though not without a certain psychological effect upon the masses, need not be taken very seriously. Nor is it necessary to dwell upon the writings of General Bernhardi, Colonel Frobenius, and others who acquired a sudden notoriety on the declaration of war. Far more important, and yet almost unknown in England, is the figure of Paul Lagarde, who even before the war had come to be more and more recognised as the true spiritual father of Pan-Germanism. In private life, Lagarde was Professor of Oriental Languages at Gottingen, and a scholar of high distinction, whose work marked an epoch in the study of the Septuagint and Greek patristic literature.

But Lagarde's true significance lies in the collection of "German Writings" (*Deutsche Schriften*), in which he concentrated his political creed. Compounded of a fervent Protestantism of the period which preceded David Friedrich Strauss, an uncompromising anti-Semitism, based upon an inversion of the New Testament, and an ultra-Conservative outlook upon social problems, he stated his main political thesis as follows in a letter of dedication to Prince William (now William II.) in 1886: "Little Germany is only to be regarded as a perhaps inevitable and necessary stage on the march towards Great Germany, just as the North German Confederation was a stage towards the present German Empire." In his view, the proper work for the German race was colonisation: and the non-German districts of Austria-Hungary and Germany must be Germanised, if not even Prussianised. He accepted Italian unity, and looked upon Croatia and Serbia as capable of forming an independent state, "because inhabited by a homogeneous and cultivated population and contiguous with kindred tribes." But the Turks, Magyars, and the whole Ural-Altaic stock are, he argues, played out; while "Magyars, Czechs, and other such nationalities under the sceptre of Austria are a burden upon history, but can serve as the mortar for a nobler race." German colonisation, then, must be conducted on a careful strategic plan, extending throughout the Polish, Slovak, Czech, and Magyar territory. Germany must find new and strategically tenable frontiers, annexing on the west Alsace-Lorraine as far as the Argonne, and on the east Russian Poland as far as the Pinsk marshes. Under no circumstances must Germany's frontiers towards Austria ever become those of a hostile state. Central Europe ("Mitteleuropa"), then, must be regulated anew, as a pledge of peace: an indissoluble offensive and defensive alliance must be followed by the Germanisation of Austria. "They all"—Magyars, Czechs, Jews, etc.—"hate us, because they know that our life is their death, and that without us they cannot exist spiritually, and in spite of this will not recognise our superiority." In 1875 Lagarde was already urgently advocating a scheme of German colonisation in Posen and West Prussia, "when not a soul in authority thought of the need for making a stand against the Slavs in the East"; while in 1885 he further favoured the creation of "profitable posts" for German princes in the Balkans, similar to those already existing in Rumania and Bulgaria. "Even a King of Armenia," he argued, "would, in following an Armenian policy, be just as surely following a German policy as Alexander of Bulgaria and Charles of Rumania."

Lagarde and Treitschke were the forerunners. But during the reign of William II. there has been a flood of Pan-Germanic literature, much of it fantastic and negligible, but some of it strangely prophetic in the light of recent events. A few of its most characteristic products deserve special attention.

In 1895 an anonymous Pan-German writer published, under the title of "Great Germany and Central Europe in the Year 1950," a book which enjoyed considerable vogue by reason of its audacious and detailed programme. According to it, Germany was to be transformed into the "Great-German League" by absorbing the Austrian Empire, Holland, and Belgium, the Walloon districts of which would fall as a sop to the French Cerberus. Thus Rotterdam and Antwerp on the north, Trieste on the south, would become German ports, the possession of

the latter being, in the opinion of this writer, as in that of Lagarde, a matter of life and death. But this league is to be but the foremost member of a "Great German Customs Union," of which the other five members are to be a Baltic Principality; the Kingdom of Poland; Greater Rumania, conceived as a buffer state between Russia and the Balkan Slavs; a Kingdom of the Ukraine, including Odessa; and Greater Serbia. The German Navy would thus be supreme on the Adriatic and the Black Sea. To-day who would dare to dismiss the programme as a mere Utopia?

An abler and extremely popular exposition of a similar theme is the pamphlet of Karl von Winterstetten — "Berlin-Baghdad: New Aims of Mid-European Policy"—whose programme is summed up as follows: "New peasant land, a great economic area, the salvation of Germanism in the Danubian Monarchy, the union of all Germans, a free path to the South-East, protection of the non-Slav races of the South-East against Pan-Slavism—in short, Berlin-Baghdad . . . On the execution of this task depends the future of our race. If we fail, there is no more habitable land in the world for the Teuton to hold as master, and it will be our fate to be cultural manure." Similar ideas underlie the writings of Count Reventlow, whose very able books on "Germany's Foreign Policy" and "The Vampire of the Continent" (a polite attention addressed to England) have had infinitely greater influence on German opinion than Bernhardi's pseudo-philosophy, but have not received the same free advertisement in England. Since the war another book, entitled "The New Triple Alliance" (*Der neue Dreibund*), by Ernst Koehler, has been much discussed in Germany. The *rôle* assigned by him to Germany is that of "liberator of the Western Slavs." Russia is to be driven eastwards, Finland is to be restored to Sweden, Poland and the Ukraine liberated. This is an interesting "liberal" variation of the orthodox Pan-German view, that Galicia may well be thrown to Russia as ballast from the Austrian balloon, while the German and Slovene provinces of Austria would be included in the German Empire as a new kingdom, the Eastern Adriatic coast would become a "Reichsland" on the analogy of Alsace-Lorraine, and the Austro-Hungarian Navy would be incorporated in the German. The extreme doctrine of absorption in Germany, preached so unashamedly by the Pan-German deputies in the Austrian Parliament for years past, has to-day received a more decorous form. Instead of cheers for the Hohenzollern dynasty and an open invitation to civil war and a Prussian invasion of Bohemia, we are presented with the theory that "Austria must exist for Germany," and that "it will be Germany's task after the war to transform the old Austria into a new German Austria."

Amid all this literature one book stands out pre-eminent—"Mitteleuropa," by the Radical politician and economist Friedrich Naumann, one of Germany's sanest and most serious political thinkers. Without a trace of rant or sabre-rattling, on the basis of wide knowledge, both historical, political, and economic, and in eloquent yet sober language, he builds up an elaborate argument for the fusion and consolidation of the two Central States after the war, as a single unit with a solid front to the outer world. The Northern Powers, Holland, Switzerland, and the Balkan Peninsula are not to be included at the very outset; they still have a little time before them in which to make their choice. The essence of his plan is to create the kernel; all the rest will follow automatically. All historical particularism must be wiped out by the stress of world-war, in so far as it may interfere with the idea of unity. This war, he argues, is not merely a German war, as so many leading Germans claim, but the crucible in which "Mitteleuropa" is to be shaped. Nor must Naumann be regarded as a mere Jingo; for almost at the outset he protests against Bethmann-Hollweg's theory of the decisive struggle between Teuton and Slav and condemns it as an insult to the Czechs, Poles and Slovenes, all of whom must be brought to realise their identity of interests and common future with the Germans and Magyars. "Mitteleuropa" must be the fruit of joint economic labour, but also of joint intellectual effort, and must lead to emancipation from the spell of French and Russian influence. It means an end to the old jealousy of Prussia and Austria, of Berlin and Vienna. "An united nation of brothers" (*ein einig Volk von Brüdern*) must revive the old conception of the mediæval Empire, organised on the intensest possible modern methods. Questions of language and religion may be treated as side issues, so long as there is unity in essentials. The root fact upon which Naumann rests his whole argument is the argument that Germany must either abandon the idea of being a world power, or organise Central Europe under her ægis as an economic unit. The days of small states being numbered, and our century being marked by the development of vast world-states, "Mitteleuropa" is essential, if there is to be something

German to place beside the British and Russian Empires, the French colonial empire, China and Japan, the United States, and Spanish America, the six great organisms which the nineteenth century has formed, or which are still taking shape before our eyes. Throughout the book Naumann's tone remains eminently sane, and if all Germans shared his outlook and his moderation it is probable that there would long ago have been such a development on entirely peaceful lines. But developed further according to the tenets of Treitschke and Lagarde, of Prince Bülow and Bassermann, of Rohrbach and Schiemann, it would swiftly become a terrible danger to the rest of Europe, which is scarcely able as a coalition to resist Germany's impetus, and might be reduced to helplessness if all the resources of Mitteleuropa, including her Polish and Balkan conquests, could be organised by the relentless system of Potsdam.

Mitteleuropa is the first stage. The second—that of "Berlin-Baghdad"—is also far from new. Quite apart from Moltke's dream of a German Palestine, we find Roscher, in 1848, arguing that Turkey's heritage should fall to Germany. In 1846 List proposed the Baghdad Railway and German colonisation of Asia Minor; and similar ideas can be traced in Rodbertus, Lassalle and others. Though Bismarck affected indifference for the Eastern Question, it was his *rôle* as honest broker at the Congress of Berlin which first opened the door to German influence at Constantinople. In 1882 the first German military mission was sent to reorganise the Ottoman army; and though Von der Goltz never obtained enough power to make his reforms effective, the German military tradition was firmly established in Turkey, and with it the connection of Krupp as the furnisher of war material. In 1886 the Orientalist Sprenger published a book on "Babylonia: the richest Land of the Past and the most Remunerative Field of Colonisation in the Present," and declared it to be the sole country not yet occupied by a Great Power. Kaerger, too, advocated Asia Minor as a field of colonisation. Their writings coincide with the period when German engineers and emissaries of the Deutsche Bank were founding the Anatolian Railway Society and building as far as Angora and Konia. The Pan-Germans, of course, pushed the idea of a protectorate of Asia Minor and the acquisition of Mesopotamia and Syria. Among numerous students of the ground was an artillery officer, Kannenberg, who in 1897 published a monograph on "Asia Minor's Natural Riches," and who, significantly enough, was accompanied by an officer of the German General Staff. A year later it was William II. himself who, as the "Imperial commercial traveller," propagated the German idea in the Middle East. At Damascus he proclaimed himself the "friend for ever" of the whole Mohammedan world. At Jerusalem he chose the anniversary of the nailing of Luther's theses on the church door of Wittenberg to reiterate Luther's famous resolve "to maintain this field." In Constantinople he extracted from the blood-stained hand of Abdul Hamid, still reeking from the Armenian massacres, valuable commercial concessions for the Germans in Asia Minor. In 1899 the Porte concluded with Dr. Siemens, of the Deutsche Bank and the Anatolian Railway Company, a comprehensive contract, conceding to Germany in principle the whole railway system as far as the Persian Gulf. In 1902 the actual right of construction as far as Baghdad was also conceded. The complicated negotiations and intrigues which followed this event, and led to more than one important modification of the original contract, are not suited for treatment in a paper which covers so much ground as my present subject, and I hesitate to enter into details of which our Chairman has an infinitely deeper knowledge than I can claim. But it is essential to emphasize the need for careful study of this policy of "peaceful penetration" by which Germany prepared the way for what her leaders glory in describing as "the German War." The tireless work of the Deutsche Bank, and the brilliant writings of Von der Goltz Pasha, Paul Rohrbach ("The German Idea in the World"), Hugo Grothe, and many others, have done much to popularise the idea that Mesopotamia and Asia Minor are destined to become "an economic substitute for the lack of a German Canada or Australia," and it is essential that we should be well informed as to the views of the enemy, both before and during the war, on this subject. It is all the more essential, because the secret negotiations between the British and German Governments regarding the Baghdad railway, in the eighteen months which preceded the outbreak of war, appear to have been based upon a complete failure on the part of our leaders to comprehend the very elements of the situation in the Near East.

I cannot pretend to have offered you anything approaching a clear picture of German designs. Whether real statesmanship on our part during the years following King Edward's death would

have averted the conflict by convincing Germany that the risks of the game were too great is a question which would lead too far afield. The essential fact is that under William II. Germany has been plagued by vast ambitions and growing unrest, which finally took the form of a challenge to all Europe in arms. To-day it is no longer possible or necessary to argue about the exact strength of Pan-Germanism on the eve of war. For in war moderate counsels are necessarily thrust into the background on every side; and to-day Germany is writing the Pan-German programme in letters of blood on the face of Europe. Her alliance with Austria-Hungary has become more indissoluble than ever, and the idea of a customs union, as a final seal upon the bond, is being propagated by prominent politicians, publicists, professors and bankers. Three members of the Austrian Cabinet who opposed the idea were driven from office during last winter. Germany reorganised the Austro-Hungarian Army when it had reached breaking point, and does not mean to relinquish the control which this fact has given to her. To all intents and purposes Mitteleuropa is shaping before our very eyes. Turkey and Bulgaria are in the German grip, and the consummate folly of our statesmen in deserting Serbia and intriguing with Bulgaria has thrown away an invaluable strategic position, brought untold misery on a gallant Ally, and opened the gate to Constantinople, which it was alike our duty and interest to block. To-day we are faced by a solid mid-European *bloc* of 120 millions, which can only be shattered or pared down by military effort, but cannot be split up by diplomacy; by the maturing project of a kingdom of Poland under a German or Austrian sovereign, as an annexe, industrial, agricultural and military, to Germany; by the prospect of a Balto-Lithuanian state, also under German rule; by the certainty that Serbia will be annexed to the Habsburg Monarchy unless we can deliver her by force of arms; by the no less certain prospect of Bulgaria, under King Ferdinand, continuing as a vassal of Austria-Hungary and Germany; and of Turkey, reorganised and exploited by Berlin, becoming a constant menace to Egypt, Persia and Arabia.

This situation cannot be met by a few vague phrases about Prussian militarism, admirable eighteen months ago as a first statement of our case, but to-day worthless unless translated into more precise and concrete terms. Unless we are prepared to desert our Allies and conclude an ignominious peace with Germany, we must counter the German plan of "Mitteleuropa" and "Berlin-Baghdad" by placing obstacles in its path. Germany can only be defeated if we are prepared to back the Slavs and liberate the Slav democracies of Central Europe. Our barrier to the German *Drang nach Osten* must be sixfold. (1) Poland, freed from its long bondage and reunited as a state of over 20,000,000 inhabitants, on terms of close intimacy with Russia, will be able to develop still further her great natural riches, and to reconstruct her social system on the lines of Western democracy. (2) Bohemia, who has been the vanguard of the struggle against Germanisation for eight centuries and has proved herself the most modern, the best organised and educated, and the most virile and persistent of all the Slav races, will, as an independent state possessing natural frontiers, strong and self-supporting industries and keen national consciousness, become one of the greatest assets in the struggle against Pan-Germanism. (3) The small and landlocked Serbia of the past will be transformed into a strong and united Southern Slav state upon the eastern shore of the Adriatic, no longer seething with unrest as the result of Magyar misrule in Croatia and Austrian economic tariffs, but free at last to develop a national life which has resisted five centuries of Turkish oppression. As a second line behind these three Slavonic states, we should aim at creating (4) independent Hungary, stripped of its oppressed nationalities and reduced to its true Magyar kernel, but for that very reason emancipated from the corrupt oligarchy which has hitherto controlled its destinies, and thus enabled to develop as a prosperous and progressive peasant state; and Greater Rumania, consisting of the present kingdom, augmented by the Rumanian districts of Hungary, Bukovina and Bessarabia. Behind these again would stand Greece and Bulgaria as national states, the latter purged of her evil desire to exercise hegemony over the Peninsula. Finally, Russia would control Constantinople and the Straits, thus restoring the Cross to its true place upon the Golden Horn, and at the same time satisfying that longing and need for an access to the open sea which has underlain Russian policy for at least two centuries. As a free port for all comers, Constantinople could only gain by a Russian protectorate, and the special rights of Rumania in the Black Sea and the Straits would receive the fullest recognition.

The alarmist will seek to oppose such a programme by the argument that it involves assigning the German provinces of Austria to

Germany, and thus aggrandising an enemy whom it must be our aim to weaken by every means in our power. Such arguments are, however, entirely specious. In the first place, there is no power on earth which could keep the Germans of Austria and of the Empire apart if once they determined to unite; and it is quite impossible for us to lay down the principle of nationality as the basis of settlement and then to deny it to the most powerful and compact of all the European nations. Moreover, in the event of our victory—and all such speculation is worthless in any other event—Germany will presumably lose the greater part of Alsace-Lorraine and Posen; and thus any access of Austrian territory would leave her virtually where she was before. But the decisive reason is the fact that the sole alternative to the completion of German national unity is the survival of Austria-Hungary; and in present circumstances this can only mean the latter's reduction to complete military, political and economic vassalage to Germany. The events of the war have amply demonstrated the Dual Monarchy's dependence upon German discipline and organising talent; and, if for no other reason, this dependence will tend to increase more and more rapidly as a result of economic exhaustion and imminent bankruptcy. Possible failure in other directions will only strengthen Germany's hold upon the Monarchy, which, according to the Pan-German plan, is regarded as a fertile field for German colonisation. In other words, we are faced by the alternative of breaking up Austria-Hungary —in which case Germany obtains an addition of eight or nine million inhabitants, but is restricted to her natural limits and is surrounded by new and virile national states—or of permitting its survival, and thus securing to Germany the final assertion of political control over its fifty-one million inhabitants, and thus indirectly the mastery of Central Europe and the control of the Adriatic, the Balkans, and Constantinople.

The twentieth century is the century of the Slav, and it is one of the main tasks of the war to emancipate the hitherto despised, unknown or forgotten Slavonic democracies of Central and Southern Europe. If the Poles, the Czecho-Slovaks and the Jugoslavs succeed in reasserting their right to independent national development, and to that close and cordial intercourse with the West to which they have always aspired, they will become so many links between the West and their Russian kinsmen, and will restore to Europe that idealism which Prussian materialist doctrine was rapidly crushing out. Establish one nation supreme over the Continent, controlling the destinies of a whole group of its neighbours, and you most surely inaugurate a new era of armaments and racial strife, accentuated tenfold by revolution, bankruptcy and social upheaval. The theory of racial domination, whether it be Prussian, Magyar, Turk or Bulgarian, must be replaced by a programme of free and untrammelled development for every race. The supernation must follow the superman into the limbo of history.

The Chairman (Sir Edwin Pears), in moving a hearty vote of thanks to the author for his interesting paper, said he hardly knew what was the right adjective to apply to it: it was brilliant, it was academic, it was thoughtful; and it suggested that English people had not given the amount of thought that they ought to have given to the subject. It did not follow, of course, that they were all bound to agree with every proposition put forward by the author. The author had alluded to him as knowing something about the development of the railways in Asia Minor, and it was true that he had watched the question "from Berlin to Baghdad" during the last thirty years. Twenty-five years ago he was strongly urged by Austrian friends to buy land in Macedonia, for they said that Austria was going to annex Serbia, reach Salonica, and take possession of all that part of the country within five years. He was glad to say he did not take their advice, but the constancy and persistency of the idea of Austrians and Germans that Serbia was in the hands of Austria, and that Austria could annex Serbia whenever it liked, was astonishing to those who knew the country. Five years ago he met, at a well-known club in London, the representatives of four of the leading papers of Vienna and Budapest, one of whom said to him: "You know you in England over-estimate the power of Russia enormously. As for our being able to annex Serbia, we can have it when we like, and you are mistaken in thinking that Russia could stop us." He turned to the other three and asked them if that was their opinion too, and they all said, "Yes, undoubtedly Serbia is in the grip of Austria and cannot escape from it." With regard to the construction of the railway from Constantinople towards Baghdad and the Persian Gulf, he was concerned in the Arbitration on behalf of the British and Austrian subjects who were dispossessed of their land at the head of the line, between Constantinople and Ismid, and obtained £133,000 as compensation for them, but the Germans got the line all the same. The various rumours that had been circulated about Enver Pasha were nonsense; he had really been to the Taurus to see whether the tunnels had been completed and were ready for the passage of the troops. Once the mountain tunnels had been made, it was

an easy matter to reach Aleppo, and to continue on to the Euphrates. A friend had driven his motor-car from Smyrna to Baghdad and declared that there was no finer ground in the world for motoring over than the desert there; it was just of the right consistency and flexibility. If the Government would spend a few hundred pounds in repairing the roads to the river-bed and up again on the other side, that journey, which now occupied three weeks or a month, could be performed in four days. The railway there was rapidly being completed, but neither that railway nor the English irrigation scheme would convert Mesopotamia into the paradise that the Germans imagined. The railway would be of advantage to the peasants of the country, as it would enable them to convey their produce to market, and in that connection he had nothing to say against the Germans, as it was a case of peaceful penetration. Great efforts had been made to plant German colonies along it, but they would all fail from beginning to end. He knew Palestine fairly well, and could say with certainty that, except for two or three settlements of Second Adventists, there were no German colonies in Palestine. He had no objection to peaceful penetration by Germany, but when it came to a question of a railway from Berlin to Baghdad, destroying the hegemony of Serbia, of Macedonia, of Turkey, and so on, that was a matter that should be strenuously opposed.

The resolution of thanks was carried, and the meeting terminated.

GENERAL NOTES.

INSTITUTION OF NAVAL ARCHITECTS.—The annual meeting of the Institution will be held in the hall of the Royal Society of Arts on Wednesday, April 12th, and Thursday, April 13th, commencing each morning at eleven o'clock. The usual annual dinner and evening reception will not take place this year. A list of the papers to be read will be found in the usual list of meetings at the end of next week's *Journal*.

CANADIAN FISH.—The first big consignment of Canadian fish for the Canadian troops now in Europe has lately arrived in England. It is made up of salmon and halibut from the Pacific Coast and soles from the Maritime Provinces. Another shipment will contain lake whitefish and herring from Lake Superior, and about forty tons of lake and sea fish are to be sent over weekly. They are all frozen, and sent to St. John in cold-storage cars, and then put into the cold storage of the ship, so that they may arrive at the camps in a frozen condition, just as the soldiers have been used to having them at home.

MEETINGS OF THE SOCIETY.

ORDINARY MEETING.

Wednesday afternoon, at 4.30 p.m.:—

APRIL 5.—ARTHUR S. JENNINGS, "Painting by Dipping, Spraying, and other Mechanical Means." Major P. A. MACMAHON, R.A., LL.D., D.Sc., F.R.S., will preside.

FOTHERGILL LECTURE.

Monday afternoon, at 4.30 p.m.:—

EDWARD A. REEVES, F.R.A.S., F.R.G.S., "Surveying, Past and Present." Three Lectures.

Syllabus.

LECTURE II.—APRIL 3.—*Present position of Surveying and Mapping of the World.* General account, illustrated by maps and diagrams showing (1) parts of the world topographically mapped from reliable surveys, (2) those less accurately mapped from surveys chiefly non-topographical, (3) parts only roughly mapped from route traverses, and (4) those still entirely unsurveyed—Facsimiles of MS. maps of well-known explorers—Specimens of different kinds of surveys from which the earth has been mapped, with general account of them—Part taken by the Royal Geographical Society in promoting exploration and surveying—Work of the future.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 3...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Fothergill Lecture.) Mr. E. A. Reeves, "Surveying: Past and Present." (Lecture II.)

Victoria Institute, Central Hall, Westminster, S.W., 4.30 p.m. Rev. Professor D. S. Margoliouth, "The Influence of German Philosophy in bringing about the Great War."

Electrical Engineers, Institution of (Local Section), Technical College, Bristol, 5.30 p.m. Mr. H. Joseph, "Hire and Maintenance of Continuous-Current Motors."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, Society of, Caxton Hall, Westminster, S.W., 5.30 p.m. Mr. J. E. Lister, "Modern Coal and Coke Handling Machinery."

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m.

Geographical Society, Burlington-gardens, W., 8.30 p.m. Colonel Sir Thomas Holdich, "Geographical Problems in Boundary Making."

TUESDAY, APRIL 4...Sociological Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8.15 p.m. Dr. C. W. Saleeby, "Imperial Eugenics."

Royal Institution, Albemarle-street, W., 3 p.m. Professor F. Keeble, "Modern Horticulture. Lecture II.—Growing Time and Seed Time."

Alpine Club, 23, Savile-row, W., 8.30 p.m. Mr. J. Stogdon, "Random Memories."

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. 1. Discussion on Sir G. C. Buchanan's paper, "The Rangoon River-Training Works." 2. Mr. R. F. Grantham, "The Present Conditions of Arterial Drainage in some English Rivers."

Zoological Society, Regent's Park, N.W., 5 p.m.

Röntgen Society, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8.15 p.m. 1. Mr. J. P. Neate, "A Chronograph constructed to work with the Electroscope." 2. Messrs. B. H. Morphy and S. R. Mullard, "The Enclosed Tungsten Arc as a source of Ultra Violet Light." 3. Mr. E. Schall, "Experiments with a Coolidge Tube." 4. Mr. H. E. Donnithorne, "A New Modification of the Ionization Method of Measuring X-Rays." 5. Exhibition of Plates showing "Experiments with the Coolidge Tube in Radiography."

WEDNESDAY, APRIL 5...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. A. S. Jennings, "Painting by Dipping, Spraying, and other Mechanical Means."

Civil Engineers of Ireland, Institution of, 35, Dawson-street, Dublin, 8 p.m.

Geological Society, Burlington House, W., 8 p.m.

Sanitary Engineers, Institute of, Caxton Hall, Westminster, S.W., 7 p.m. M. Andre Le Marchand, "Planning for a Manufacturing Town of 50,000 Inhabitants."

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m. 1. Messrs. W. R. Schoeller and A. R. Powell, "On the Alkalimetric Estimation of certain Bivalent Metals in the form of Tertiary Phosphates." 2. Mr. P. A. E. Richards, "Note on a Specimen of Russian Oak." 3. Mr. A. H. Bennett, "The Estimation of Potassium in presence of other substances."

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. 1. Dr. A. C. Fryer, "The Monumental Effigy of Bridget Countess of Bedford at Chenies." 2. Dr. P. Nelson, "The Effigy of a Thirteenth-Century Abbot of Ramsey. Some further examples of English Mediæval Alabaster Tables."

THURSDAY, APRIL 6...Faraday Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Dr. W. Rosenhain, "The Making of a Big Gun." (Illustrated by cinematograph.)

Royal Society, Burlington House, W., 4.30 p.m.

Linnean Society, Burlington House, 5 p.m. 1. Professor G. C. Bourne, "On Five New Species of *Edwardsia*, Quatr." 2. Professor W. J. Dakin, "A New Species of Enteropneusta from the Abrolhos Islands." 3. Dr. O. Stapf, "The Southern Elements of the British Flora."

Chemical Society, Burlington House, W., 8 p.m. 1. Mr. J. N. Collie, "A space formula for benzene." (Part II.) 2. Earl of Berkeley, "A new form of distilling flask, together with a note on benzyl benzoate." 3. Mr. J. W. Smith, "3-Phenanthrol-4-aldehyde."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. W. H. Hadow, "English Music in the Tudor Period. Lecture II.—Secular Part Music."

FRIDAY, APRIL 7...Royal Institution, Albemarle-street, W., 5.30 p.m. Mr. W. S. Lilly, "A Plea for War."

Engineers and Shipbuilders, North-East Coast Institution of, Newcastle-on-Tyne, 7.30 p.m.

Geologists' Association, University College, W.C., 7.30 p.m. Mr. M. Odling, "Notes on the Corallian of the Oxford District, with special reference to the Occurrence of a Pebble-bed at a Constant Horizon."

SATURDAY, APRIL 8...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Radiations from Atoms and Electrons." (Lecture V.)

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—March 31, 1916.

Journal of the Royal Society of Arts.

No. 3,307. VOL. LXIV.

FRIDAY, APRIL 7, 1916.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, APRIL 10th, 4.30 p.m. (Fothergill Lecture.) E. A. REEVES, F.R.A.S., F.R.G.S., Map Curator and Instructor in Surveying to the Royal Geographical Society, "Surveying: Past and Present." (Lecture III.)

TUESDAY, APRIL 11th, 4.30 p.m. (Colonial Section.) SIR DANIEL MORRIS, K.C.M.G., M.A., D.C.L., D.Sc., F.L.S., "The Forest Resources of Newfoundland." THE RIGHT HON. SIR WILLIAM MACGREGOR, G.C.M.G., C.B., LL.D., D.Sc., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

COLONIAL SECTION.

Tuesday afternoon, March 28th, 4.30 p.m.; DUGALD CLERK. D.Sc., F.R.S., Chairman of the Council of the Society, in the chair. A paper on "Next Steps in Empire Partnership" was read by PERCY HURD, joint author of "The New Empire Partnership: Defence, Commerce, Policy."

The paper and discussion will be published in subsequent numbers of the *Journal.*

FOTHERGILL LECTURES.

On Monday afternoons, March 27th and April 3rd, 4.30 p.m., Mr. EDWARD A. REEVES, F.R.A.S., F.R.G.S., Map Curator and Instructor in Surveying to the Royal Geographical Society, delivered the first and second lectures of his course on "Surveying: Past and Present."

The lectures will be published in the *Journal* during the summer recess.

JOURNAL.

The Government limitations on the importation of paper and paper-making materials have rendered it necessary to restrict the *Journal* to the smallest possible size. For the present, therefore, its contents will be confined as far as possible to a report of the actual proceedings of the Society, and it may be necessary occasionally to publish reports of the meetings a little less promptly than has always been the practice.

It is hoped that the Fellows will appreciate the necessity of such restrictions, and it is also hoped that the *Journal* may be able to expand to its normal size at an early date.

PROCEEDINGS OF THE SOCIETY.

SEVENTEENTH ORDINARY MEETING.

Wednesday, April 5th, 1916; MAJOR PERCY A. MACMAHON, R.A., LL.D., Sc.D., F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Donelan, Dermot O'C., J.P., Regent Palace Hotel, Piccadilly-circus, W.; and Sylanmore, Tuam, Co. Galway, Ireland.

Phillips, S. Charles, M.S.C.I., 47, Cannon-street, E.C.

The following candidates were balloted for and duly elected Fellows of the Society:—

Deb, His Highness Raja S. Tribhuban (of Bamra), Bamra, Deogarh P.O., Sambalpur, India.

Major, John Grayling, Clevedon Lodge, West Park, Eltham, Kent.

The paper read was—

PAINTING BY DIPPING, SPRAYING, AND OTHER MECHANICAL MEANS.

By ARTHUR SEYMOUR JENNINGS, F.I.B.D.

It may safely be taken as a fact beyond doubt that the application of paint, japan, enamel and varnish by mechanical means, in contradistinction to the old-fashioned method of using brushes, effects an enormous saving

of time, and to some extent of material also. It should also be recognised that the result from the point of view of both durability and appearance is a distinct improvement on the older method. In the United States of America dipping, paint-spraying, and the application of paints and varnishes by other mechanical means are employed almost universally in the industries, and in this country such methods have been successfully used in certain factories for many years past. Of late there has been a remarkable increase in this direction in the United Kingdom, although there are not a few manufacturers who still seem slow to adopt modern methods.

It is remarkable to note that a great number of firms who have given some consideration to the subject are inclined to the idea that while paint or its equivalent may be successfully applied by mechanical means in other industries than their own, it is not suitable for the particular one in which they are engaged. Closer examination, however, proves that there are very few trades indeed using paint in which the processes may not be successfully employed, and it may surprise some of those present to learn that in at least 250 different industries dipping or spraying may be successfully and economically employed. A few of these may be mentioned in order to indicate the diversity of the articles dealt with. Paint is applied by dipping to agricultural implements on a very large scale, to casements, bedsteads, piano cases, barrows, reaping-machines, cans and a great many other articles. By spraying, paint, varnish, japan and various other protective liquids are applied to shells and to confectionery, to celluloid buttons and to motor-cars, to bird-cages and to dynamos, but the list could be extended almost indefinitely.

In my investigation of the subject I have come across a few firms who have tried one or other of the methods mentioned, but have abandoned them on the ground that the result has not been satisfactory—never, be it remarked, because they were found to be too expensive. Investigation has proved that such cases of failure have arisen either because a suitable apparatus was not chosen for the particular work in hand or the right sort of paint or japan was not used. The last cause of failure is the most frequent, as, for instance, a case placed before me some time since, in which small iron castings were painted by dipping but were found to stick together and not dry properly. Here the japan used was not suitable for the purpose, and it will be readily seen that paint or japan which might answer well if applied by means of a brush would not be suitable for application by dipping.

Without going at this stage into the question of other failures, it may be remarked that an idea prevails that the cost of plant necessary for carrying out these processes is prohibitive. This is altogether a mistake. A spraying machine with the necessary plant could be purchased for £30 or £50, although a large plant would, of course, cost very much more. The same is true in the case of dipping. If the articles to be painted are very large and very elaborate, the plant will obviously be somewhat expensive. For many purposes the tanks, hoists, etc., may be of a very simple character, as, for example, iron and steel sashes which are dipped into a narrow tank containing paint would require only a simple form of hoist with hanging rails and metal dripping floor adjoining the tank; or, simpler still, a mere boxlike tank, in which tapered varnish and paint cans are dipped by hand, a piece of wood being inserted in the neck by which to lift them in and out. The cost of such a plant need only amount to a few shillings.

It will be convenient now to divide the subject up under various heads, viz., (*a*) painting by immersion; (*b*) by spraying by means of compressed air; and (*c*) other mechanical means.

Taking these in order, a dipping plant usually consists of a tank (preferably metal lined) which contains the paint or varnish into which the article to be painted is plunged bodily. Clearly it must be of sufficient size to hold easily the article to be dipped. In the case of agricultural machinery, farm and military waggons, etc., the size and depth have to be considerable, and in this case, as a rule, an agitating apparatus at the bottom is desirable. One form consists of a shaft passing from end to end at the bottom of the tank, and provided with a paddle, while over it is provided a metal frame which may be roughly described as a horizontal venetian blind, the slats of which may be turned vertical when the agitating apparatus is working. This fitting is provided with the object of preventing the paddles being clogged by the settling paint, but it also serves to catch any pieces of wood, nails, etc., which may accidentally find their way in. As a matter of fact, a good dipping plant does not settle out to any extent, and it is sufficient if the agitating apparatus is operated each day for twenty minutes or so before starting work, and for a somewhat longer period on Monday morning.

Another form of agitating apparatus is

provided with a worm for agitation instead of a series of paddles.

As already indicated, for dipping such articles as iron sashes a very narrow but deep tank suffices, and in this case, as in many others, the agitating mechanism may be wholly dispensed with, because it must be remembered that the mere fact of plunging an article into the paint and immediately withdrawing it has the effect in itself of stirring up the paint.

Iron bedsteads are coated nowadays almost invariably with paint or japan by plunging the parts into japan, and these are afterwards stoved or baked. Iron frames of mangles and many other similar parts are also painted by dipping. Perhaps no better illustration could be given of the high degree of finish obtainable by dipping than the fact that piano cases may be finished by the method, the parts being lowered bodily into the varnish tank. Time will not permit me to give the details of the process, but I may state quite definitely that the finish is quite as good as that obtained by the use of brushes, and that the extra amount of varnish required is only about 5 per cent. I would very emphatically state that if the very fine finish which is necessary for pianos can be obtainable by dipping there can be no paint, varnish or japan finish too difficult to obtain by the method. In effect, it simply means a careful study of the requirements for the particular work in hand.

Adjoining the tank must always be an inclined metal-lined floor, over which the articles can be held to drip for a few minutes, and this floor should be connected with a trough leading to an underground tank to hold the superfluous paint, which should pass through a grating and may be pumped into the main dipping-tank as required, or, if desired, the arrangement may be such that the superfluous paint drains directly into the dipping tank.

Just as the size of the tank will vary with the dimensions of the object to be dipped, so will the type of hoist employed differ according to circumstances. I have seen a rope over a pulley used for very simple work, such as bedsteads, but as a rule a pneumatic or electric hoist is the cheapest in the end, particularly if it is worked in connection with a trolley, because it must be remembered that it will be necessary to provide a more or less elaborate system of overhead rails on which the articles can be hung to dry after dipping.

As a rule, the paints employed are sufficiently hard to receive a second coat within, say, four hours; and the system adopted at Woolwich Arsenal is a very good one, which may be confidently recommended. Two tanks are provided, one at each end of a very long room with rails between. The waggons are dipped at one end, proceed very slowly towards the other end of the room where they are sufficiently dry to receive a second coat, and on turning receive a third coat at the first tank.

I should like to emphasize the importance of a careful consideration being given to the question of the overhead rails, as I find from my inspection of a large number of factories that many of them are quite deficient in this respect. As in all details of engineering works, a saving of labour is essential to economy, and it is well to have the rails so arranged that the work passes from the finishing-room to the tank or tanks, and thence to the storage or shipping department. If this is done on a well-thought-out basis great speed can be effected.

It will be understood that the article being painted remains in the paint only a few seconds, that it is then stationed over the dripping floor for perhaps five minutes, and then proceeds along the rails for further treatment until it is finished. The question will at once occur whether this method does not produce drips, or what painters call "fat edges." The answer is, that if this occurs the paint is not properly made for the purpose. As a matter of precaution, one painter usually stands by each article as it is suspended over the dripping floor, and with a brush removes any small drips or fat edges which may occur. This labour, however, is very slight. Sometimes it is desired to put on a different-coloured finish to the work than that which is put on the under-coats; it is clear that this may be effected by using a different tank.

Before proceeding to describe paint-spraying or painting by means of compressed air, it may be convenient to compare the method with that of dipping. Without dwelling at any length on the subject, which is of a somewhat controversial character, it can be stated briefly that in arriving at a decision as to the respective merits of the two processes, one can only be guided by the shape and size of the particular article which is to be painted. A reaping-machine, for instance, is of so intricate a character that plunging it bodily into the tank is certainly preferable to spraying; on the other hand, there are many articles where spraying produces far better results than the dipping process. Sometimes both methods are used in conjunction; for example, the first or priming coat can be given by dipping and the final coat of varnish sprayed

on. Again, spraying can be used in cases where the whole article is not required to be painted, as, for instance, the body of an automobile, which if plunged would receive paint on the inside as well as the outside, which is not desired. A better way would be to spray over the whole of the outside surface, although this method, as I shall explain later, has to some extent been superseded.

There are about a dozen different makes of paint-sprayers on the market. It is hardly within my province to recommend any one of these as being superior to the rest, but those interested should carefully compare the construction and first cost before arriving at a decision as to adopting either. With one or two exceptions these machines all work in the same manner. Paint, varnish or other liquid is contained in either a cup attached to the spraying apparatus when the quantity required is small, or in a small tank connected up with tubing. Take, for example, the "Aerograph," which was the first of its kind placed on the European market. It is also the one which will be used in the demonstration which will follow my remarks. A cup containing the paint is screwed on when only a little paint is required, but when the supply is to be continuous a cap fits in the same position, and the paint comes through a supply tube. The air is supplied through a flexible tube, and there is a finger lever which controls both the air valve and the colour valve in the nozzle, so that little or much paint may be allowed to pass into the current of escaping air. This may be considered to be a general principle upon which all these sprayers work, with one or two exceptions. The amount of air pressure varies very largely with the consistency of the paint, but, generally speaking, thin liquids and varnishes may be sprayed with 18 lb. to 20 lb. to the square inch, while a maxmium of 50 lb. will cover nearly all classes of paint and similar products. In cases of very thick liquids heat may be applied to the paint tank, which will facilitate the operation to some extent.

The next sprayer is known as the "Midland." Its claims to superiority are chiefly simplicity of construction, solidity of working parts and ease of cleaning.

Another form of sprayer is the "Invincible." This instrument is so arranged that it may be used with the air pressure only if required to dust the article about to be painted.

The "Airostyle" is the next type of sprayer shown. It is made in various patterns and sizes for use with different kinds of work, and is one of the most popular instruments of the kind on the market.

The "Aeron" is another type, and the spraying is done through the cup holding the paint, excepting in the case of a considerable amount of work being done, when the paint will be placed in a container holding several gallons and held in an elevated position.

The "Eureka" is constructed on an American model. It is used with the cup only and is conspicuous for the absence of complicated parts. It is very suitable for work in which it is desired to change the colour frequently, as any number of cups filled with different colour may be on hand and the transfer from one to the other takes but a minute or so.*

Having briefly described the principal spraying apparatus available the next provision necessary is (a) the supply of compressed air, (b) the exhaust, and (c) the cabinet in which the spraying is done and which should be fitted with a turntable. There are various forms of air compressors, ranging from a small and simple one for a single spraying apparatus up to those larger and more elaborate which are required where a number of sprayers are in use. The compressors must be designed to give an absolutely pure supply of air, free from oil and grit, and the air-main must be so arranged as to avoid any trouble due to condensation. For high-class work a suitable air filter should be fitted to the intake of the compressor. It should be of large diameter, and have a gauze screen and wad of cotton wool.

As already intimated, the spraying should be done in a cabinet fitted with an air exhaust. Unless this is provided the operator may be seriously injured by inhaling the fumes from the paint or varnish or the paint itself. The exhaust is usually produced by fans, and in large works the exhaust main connects up with all the different cabinets. This question of masks is one which solves a good many of the problems surrounding the subject of paint spraying. By using masks or stencils, or both, almost any work can be done. For instance, I was recently consulted by a toy manufacturer in a large way of business as to the most economical method of painting red lines on iron parts of toy standards. I recommended a spraying machine to be used with stencils of thin metal through which the lines should be cut with breaks at intervals to hold the stencil together. Going back for a

* Slides showing the various forms of apparatus were shown.

minute, it may be mentioned that in dipping articles into paint any portion which is not required to be painted may be protected by the application of a little vaseline, and this can be rubbed off when the rest of the work is dry.

Before leaving the subject of spraying, a few words may be said as to another type of apparatus used in the open for sixteen operators on small work. These cabinets are fitted with glass sides, and it may be here mentioned that ample light, either natural or artificial, must always be provided, as otherwise some part of the work to be sprayed is nearly certain to be missed. The light should be derived from the left side of the operator or from overhead.

There are so many trades in which spraying is successfully done that it is difficult to select any one as being of special interest. A simple operation is that of painting or repainting gas-meters. In this case some parts of such work, as for instance the brass labels and name-plates, are not required to be painted. To protect them a mask of suitable shape is used. They are held in position by the stout wire appendage, and are readily put on and taken off. When it is desired to paint a very large surface, such as a gasometer, or a series of iron girders, or even a long stretch of fencing, it can best be done by using a portable spraying apparatus with motor sprayer and everything else required mounted on a platform or wheels, so that it may be moved along as the work proceeds.

An extremely interesting paint-sprayer is that designed and used by the Pennsylvania Railroad. Mr. M. E. McDonnell, Engineer, wrote: "The company does very little painting by dipping. The spray process is, however, used very extensively, a large percentage of our freight cars having been painted by this method for years. The method is very satisfactory and also economical. The saving in the cost of labour in the spraying method is approximately 60 per cent. In some cases the saving is greater than this. In one of our largest shops the cost of application per unit for a given number of square feet is $38\frac{9}{10}$ cents with the spray, as compared with \$1 with brush. It might be said that more paint is applied per coating when the brush is used. A given surface which would require 10 gallons of paint for one coat by the brush method would require approximately 7 gallons by the spray method. When painting a freight car a more uniform coating is obtained when the brush is used, due to the fact that the paint can be brushed out behind ladders and other things which would obstruct spraying, while in the application of the paint with a sprayer it is necessary to apply a thicker coating at certain points in order to reach other points which are obstructed, and which must, therefore, be approached from a side angle. The spray, however, reaches certain crevices which cannot be reached with the brush, and this is in some cases advantageous with the painting of freight equipment cars. Our company would not consider returning to the brush method of painting."

I may add to these remarks that rapid as the increase in the use of paint spraying has been of late in this country, I am convinced that there is an enormous field yet untouched, particularly in connection with portable apparatus.

Turning from comparatively rough work for a moment to the most artistic, it need hardly be said that paint-spraying may be employed for the most delicate artistic work, from retouching photographs to designs on pretty well any material.

As to the best paint for use in dipping and spraying, I need only say that ordinary paint will not answer, as a rule, because it is not of the right consistency. Supplies should be obtained ready for use or ready to be thinned by the addition of turpentine or white spirit from firms who have made a special study of the subject.

A few words now as to the method of painting or enamelling very small articles such as hooks and eyes, small castings and parts; no better method is known to me than the use of the "tumbler," which in form is similar to an ordinary churn. Inside this machine are placed a number of shot or steel balls of different sizes. The articles to be treated are then introduced, together with the japan, and the machine is started at varying degrees of speed. The shot carries the japan over the various parts and into the interstices. As different objects and materials require different speeds, some work will be started slowly and the speed increased to get the desired finish. The objects are then dumped out on to wire screens or baskets, and shaken, when the steel balls and shot fall through the mesh, leaving the articles that have been japanned behind. The baskets are then hung in baking ovens while the balls are washed in gasoline ready for use.

In order to obtain the exact amount of japan required for a given quantity of articles, the weight is taken of such articles, of the steel balls and of the japan. After a little experimenting the proportions may be formed which will result

in all parts of the articles being covered with japan without leaving any surplus whatever.

Shells.—It need hardly be said that the subject of painting shells inside and out is of great interest in these days. The paint or varnish is applied to prevent the shell rusting, and the constituents of both materials are usually settled by the War Office specifications which, however, vary considerably. White lead must not be used for the paint, zinc oxide is usually preferred, and this may be followed by yellow ochre or other earth colours, or lamp-black may be mixed with the zinc oxide to produce grey. The varnish is usually fairly cheap copal, which can be stoved or baked at a heat up to 300° F. The painting outside can be done by dipping by the aid of suitable mechanism, but the varnishing of the inside surface is more difficult. A brush or swab is sometimes used. The simplest plan is to place the shell upside down over a vertical rod communicating with the force-pump. A single plunge will send the varnish to the upper end and the inside of the shell, the varnish runs off back into the tank and the shell is then removed and placed on an adjacent perforated table to drain. Another practical method is to use an ordinary spraying machine with an extension which reaches all parts of the interior. This method is employed at the present time in many munition factories. Shellac spirit varnish is often used for small shells, and this should be slightly warmed as well as the shell itself into which the shellac may be poured and then be inverted to drain.

In a machine which is made by the Spray Engineering Co., of Boston, Massachusetts, U.S.A., an ingenious device is provided for admitting only a fixed amount of coating material at each operation. The exact amount is ascertained, the mechanism is then set to repeat precisely the same quantity, and the machine once so adjusted can be worked by an unskilled operator. The actual spraying is practically instantaneous, so that the speed is determined by the rate at which the shells are fed to and taken from the machine. What is known as Type A machine has a speed of forty miles per minute. The standard machine consists of a table with steel-supporting frame, the operating mechanism being mounted beneath the table top. The usual coating material, such as varnish, asphaltum, paint, and similar special compounds, is carried in a reservoir supported above the operating table. The liquid coating material passes down the hollow reservoir support to an adjustable measuring device controlling the amount of material sprayed at each operation. A system of levers controls the motion of the device which cuts off the supply from the reservoir and admits the measured quantity of material to a channel leading to the spray nozzle. The last part of this motion admits a compressed-air supply which drives the coating material through the spray nozzle and distributes it evenly over the surface to be coated. High working speed is thus obtained without waste of material, and one setting of the measuring device ensures the delivery of a fixed quantity of coating material to each shell.

The slide shows a general idea of the appearance of the machine and the working parts are lettered. It will be observed that the actual operation of discharging the varnish or other compound is effected by operating a foot lever.

The next slide shows Type B machine, which is adapted for coating uniformly the interior of deep shells from 3 in. to 6 in. in diameter as well as cartridge-cases for the various types of shells not exceeding, approximately, 3 in. in diameter. One feature of the machine is a moving nozzle automatically controlled. The coatings are applied to the article while in a stationary vertical position.

Type C.—This machine is designed for coating the outside of shells and cartridge-cases not exceeding, approximately, 3 in. in diameter. It is equipped with a motor-driven rotating shell table, also an exhaust fan mounted in a sheet-metal hood for protecting the operator from the paint fumes. The coating is applied while the shell is being rotated in a vertical position.

Type D.—This machine is designed for coating the inside of shells larger than 6 in. in diameter, and of those that are too heavy and too long to be handled in a vertical position. A motor drive is included for rotating the shell, also an exhaust fan as noted under Type C machine. The shell is laid on its side and rotated in a horizontal position during the coating operation. The nozzle, while spraying, is moved automatically along the shell axis, thus ensuring the uniform coating over the entire inside surface.
